THE
JOURNAL OF HORTICULTURE,
COTTAGE GARDENER.

AND
HOME FARMER.

A CHRONICLE OF COUNTRY PURSUITS AND COUNTRY LIFE, INCLUDING BEE-KEEPING.

CONDUCTED BY
ROBERT HOGG, LL.D., F.L.S.

Established

in 1848.

VOLUME XVII. THIRD SERIES.
JULY—DECEMBER, 1888. :

LONDON:
PUBLISHED FOR THE PROPRIETOR, 171, FLEET STREET.

LONDON:
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,
171, FLEET STREET.

TO OUR READERS.

ANOTHER half-yearly Volume of the *Journal of Horticulture* is completed, and its contents, to which the accompanying Index refers, we are induced to believe have not been less acceptable to our readers than those of previous issues embracing the same length of time.

Eighty-one of these Volumes are now completed, and we are glad to have made a favourable commencement with the eighty-second. The series, we think, contains a record of the true position of horticulture throughout the period of upwards of forty years; and, sound as much of the practice of the old master cultivators was, and agreeable as is this description of it, a great advance is noticeable as we approach the present time.

In variety of subjects treated, in the manner in which discussions are conducted, in the literary ability displayed by the greater number of writers, in the number and execution of the engravings, progress is apparent. This is gladdening to us, and encouraging.

The grand old gardeners of past days we can never forget, and some of their work in the garden, and, as registered in the pages in which it was presented to the world, has not been excelled; but they were few in comparison with their successors, who strive in a manner most creditable to themselves, and usefully to others, to disseminate information on the important and delightful occupation of gardening.

It is due to them that we should state that their work is appreciated by far more readers, extending over a much wider field, than they can be cognizant of. From gardeners old and young, from experienced amateurs and earnest probationers, we have letters conveying good wishes to all who share in the work which gives to them satisfaction, that helps them in their difficulties, aids in their successes, and contributes to the pleasure of their lives. From every part of the kingdom such testimony comes--from the continents of Europe and America, and from far distant Australian colonies. It is no expression of vanity when we say such testimony is pleasant to us; and it is mentioned to enable us the better to express our obligations to all our co-helpers who have effectively shared in maintaining so well the acceptability of the *Journal*, and placing it in the satisfactory position it occupies in the horticultural world.

We rejoice in the retention of old friends and the acquisition of new, to all of whom we tender our best wishes, and look forward with confidence to the interest and usefulness of the "old *Journal*" being fully sustained.

INDEX.

- ABUTILONS**, 228; **VITIFOLIUM**, 165; planted out, 484
Acacia *Riceana*, 434
Acantholimon, 210
Achimenes *gloxiniiflora*, 290
Acme weed-killer, 195
Adam's Needle, 62
Adiantum cuneatum for cutting, 13, 526; *versatillense*, 193; *Waltoni diffusum*, A. Farley-ense from spores, 335; *mann-ghum*, 406
Aeschynanthus, 479
African *Gronovii*, 436
Agapanthus umbellatus *albus*, 290; dividing, 505
Agricultural College and Merchants' Company, 386
Allamandas, 85; repotting, 549
Allium *Moly*, 22; *pedemont-ianum*, 27
Alpine plants, select, 2; notes on, 210; rockeries, 317
Alternanthera fallax, 231
Alocasia, 479; *metallica*, culture of, 207
Amaryllis, 157
Amasonia calycina, 478
American seedsmen and hmnor, 224
Ammonia for Vines, 111
Anemones, 156; culture of in pots, 505; single, 539
Annals, sowing for spring, 168, 206
Anthurium Scherzerianum, 479
Antirrhinums, 145
Antin meadowland, 206
Aphelandra aurantiaca *Roelzi*, 479
Aphis, new facts about, 537
Aponogeton distachyon, 568
Apples—*Bess Pool*, 123; *Pear-shaped*, 261; *Grand Sultan*, 265; cultivation, 270; the oldest, 277; for profit, Mr. Bannard's paper, 357; certified at Chiswick, 374; grafted on *Pears*, 385; storing, 412; and *Pears* in Wales, 440; selection of, 455; importation of American, 564
Apple crops, prospects of the, 26
Apple trees, canker in, 428
Apple and Pear Conference, 97; at Chiswick, 316, 356
Apple and Fruit Growing Company, 267
Apricots out of doors, 274; under glass, 277; selection of, 456
Aquatics for table decoration, 568
Arancaria—imbricata coning, 316; *nnheathy*, 371
Arbicultural Society (Eng-lish), meeting of the, 171, 492; visit to Chillingham Castle, 314
Arnebia echinoides, 210
Artichokes, *Globe*, 478
Artificial mnners, 54
Asclepias tuberosa, 437
Ash trees, raising from seed, 595
Asparagus stem, a fasciated, 122; plantations, 368; forcing, 528; sowing and planting, 528; and *Potatoes*, forcing in frames, 572; neglected, 595
Asphalt, 325; walks, making, 528
Asters, 124; at Chiswick, 244; *Townsendi*, 292; *Comet*, 588
Aubrietias, 3
Auricula, 156
Auricula and Carnation Societies (National), 390, 469, 546, 557
Anstralia, the big trees of, 505
Autumn, 395
Azaleas, 181; manure for, 38; Ghent, 337
BARBERIAS, 117
Battersea Park, 164
Basingstoke Show, 270
Bawtry Show, a disputed cnp, 173
Beans, *Kidney*, 323
Bedding plants—propagating, 228; keeping, 570
Bees—hopes for the harvest, 13; the weather, 37, 61; raising queens, 37, 133; the Heather harvest, 38, 157, 206, 457; glass sections, 38, 205, 436, 458, 527; general management, 61, 133; the best hive, best site, double-cased hives, 61; work for the month, 85; queen substitution, 109; Caledonian Society's Show, 109; price of honey, 157; lessons of the year, 182; at the Heather, 204, 370; changing queens, 205; preparing for winter prospect, 229, 369, 370; paint and tar for hives, 230; erroneous advice on, 253; removing from a building, 254; the closing season, 276; notes on, 299, 571; combination hive, 300, 370; introducing queens, 301; how to begin, 323; notes on bad seasons, 347; Carno-lian queens, 348; snipers, 370, 504; and their enemies, birds eating, 391; sections, 418; as educators, 414; feeding, 435; the "long idea" hive, 456, 470; which way do they naturally build their combs? 456; in what part of the hive do they store their honey? which race is best, are Cyprians spiteful? Pond's *alias* Sim-min's system of queen intro-duction, 457; the peculiarities of the season, "A Lanark-shire Beekeeper's hive, 480; signs of the times, 503; how long do queens lay? 504; wintering, 527; supering, 549; at Christmas, 593
Beetroot, storing, 368
Beet, Carter's turnip-rooted, 290
Begonias—C. Showell, 148; for winter-flowering, 156; General Chichester and Mrs. Stark, 335; *Scharffii*, 539; at *Maister-*son; new, 196; at *Maister-*son, 222; wintering, 280 455; at Forest Hill and Swanly, 314
Berkeley Castle, 337
Berlin exhibition, 516
Bertolonia, 156
Birch, purple-leaved, 437
Birds and caterpillars, 391
Birds, notes on, 409
Birmingham Chrysanthemum Society's dinner, 583
Birmingham gardeners at Reading, 218
Bocconia cordata, 290
Bollea Wendlandiana, 76
Bolton Hall, 518
Book, review of—Drury's "Choice British Ferns," 57; "Cultivation of Bulbs," 97; "Cultivation of the Pansy," 222; "The Rose Garden," 547
Books on botany, 594
Botanic (Royal) Society's Fête, 26
Botanic Society (Royal) ar-rangements for 1889, 564

Botany—the study of, 247; pro-gress of, 296, 344, 352; geo-graphical classification, 305; Dar-winian theory, 344
Bougainvilleas, 85
Bonquets at exhibitions, 18
Bonvardias, 228; for cutting, 13; at Bristol, 517
Box, use of the wood of, 99
Brentwood Show, 297
Brighton Show, 272
British Fruit Growers' Asso-ciation, 303
Broccoli dying, 135
Brookfield Horticultural So-ciety, 122
Bromeliads, 158
Brussels Sprouts, culture for profit, 22
Bulbs—planting, 299; rationa-le of potting and planting, 437
Bunyard's nursery, notes on, 444
Buttercups, poisoned by, 189
Buttonhole holder, 504
CABBAGES AT CHISWICK, 26; and Onions for early use, 33; competition, 49; for spring, 90, 117, 138, 186, 478; clobbinz, 111; Express, 123; white hearted, 134; a critique, 163, 218; old, 180; at Chiswick, 186; *Ellam's Early* and *Early York*, 242; planting, 275; 424
Cactuses, notes on, 115, 172
Cesalpinia japonica, 9
Caladium, 85
Calanthe Veitchii, 406
Calanthes in winter, 581
Calceolarias, 133, 276; *mexicana*, 138; and *Cinerarias*, notes on, 456; falling, 573
Calendula pluvialis, 138, 196
California, fruit culture in, 590
Calopogon pulchellus, 147
Camellias, 43, 181, 276; potting and managing, 188; buds fall-ing, 532
Campanula isophylla *alba*, 191
Cannas, 456; new, 196, 293; *Ulrich Brunner*, 335
Canker in fruit trees, 398, 478 544, 555; Mr. Tonks' paper, 376; its cause and cure, Mr. Douglas's paper, 497
Carladovica palmata, 321
Carnation and Picotee Society's Show (National), 77
Carnation (National) Society's meeting, 390
Carnations, notes on, 47; *Comte de Chambord*, 93; layering, 108; and *Picotees*, 121; tree, 124; Mrs. Reynolds' *Hole*, 147; R. H. Elliott, 148; border, 211; Edwin Molyneux, 219; Madame *Carle*, 244; good border, 277; Mrs. Reynolds' *Hole* and *James Fitzpatrick*, 243
Carpenteria californica, 27
Carrot, the *Guerande*, 48; stor-ing, 413
Carya alba, 137
Castle, death of Mr. R., 539
Casuarina muricata, 321
Catherham Gardeners' Society, 423
Caterpillars—a plague of, 8, 12 56; some conspicuous, 63; wood burrowing, 278; in 1884, 343
Cattleya Harrisii, 388; C. Lam-berhurst Hybrid, 389
Cauliflowers, 413; plants, young, 275
Celery, 181; earthing up, 275; clean, 305; decaying, 392; fly, 459
Celosias, 133
Centranthus ruber, 98
Cercis siliquastrum, 22
Cereus grandiflorus *Maynardi*, 172; seedling, 173
Cheltenham Show, 273
Cherry trees under glass, 37
Cherry house, the, 322, 412
Cherries, selection of, 456; fore-ing, 518
Chichester Gardeners' Mutual Improvement Society, 317
Chicory, the *Asparagus*, 536
Chillingham Castle, 314
Chiswick, notes at, 419
Chiswick Gardeners' Mutual Improvement Association, 406

IN THE VINERY.

PROBABLY some of the happiest hours in many a man's life have been spent in the vinery, and some also the most anxious—not to say painful. When all goes well, and the work of thinning, dressing, and otherwise attending to Vines can be done at the right time, and every day shows satisfactory progress in growth, the leaves increasing in texture and deepening tints of green, indicative of health, and when the fruit swells steadily onwards to maturity, no scalding or rusting of the berries, no red spider, thrips, or mealy bug attacking the foliage, and no fear of shanking entertained, then the hours spent in the vinery are happy hours to the amateur or gardener who delights in the culture of this princely fruit. But on the other hand, when work of various kinds presses to be done, and a little time can scarcely be snatched for tending the Vines; when laterals are rambling wildly and cannot be reduced; when the berries are wedging against each other and cannot be thinned; when insects are insidiously establishing themselves and cannot be subdued; when the dreaded shanking is expected and there is little hope of averting it, then the vinery is a source of deep anxiety, and the moments spent in it are moments of misery. Granting, however, the existence of the drawbacks indicated, and they are stern facts, there yet remains another fact to be recognised, for it cannot be ignored, that the best is not always made of the means at disposal in the management of Vines. Moments are lost that might be utilised, and errors committed that ought to be avoided, and especially as their avoidance is as easy as their committal.

Having had opportunities for spending a little time in vineries lately in different gardens and not in the same district, in which both good and bad management was apparent, and good and bad crops of Grapes advancing accordingly; when in some houses the temptation was great to linger and admire, and from others it was a treat to escape, perhaps a few hints appropriated under the circumstances may not be unacceptable if recorded as suggesting lines of guidance on the one hand that may possibly be of service to some who may not be pursuing the right path, or as warnings on the other for the benefit of the undecided who are in doubt as to which course to take in their procedure. As the leading object of these notes is neither to administer reproach to men who fail nor to accord praise to those who succeed in Grape-growing, the houses and the Vines in them shall be referred to under numbers, and it is hoped no one will seriously object to the arrangement.

No. 1 vinery.—A new range, admirably adapted for the purpose, and in which the Vines have been planted two years. Some of them have made good growth and are bearing prodigiously; others have a stunted appearance, with small light green, rusted or warted leaves, and the house on the whole is very unsatisfactory—one to be left as speedily as possible without hurting the feelings of the “manager.” It is, in truth, more than he can manage. The garden has been enlarged, and Vines are new to a good worker and vegetable grower, who would be happier in the outside department, and might with great advantage to the owner of the garden and himself make room for a competent man for the “glass.” Perhaps this will be so. The borders were made the full width of the house inside, also outside, and “lots of manure” was used. Strong fruiting canes were planted, the soil shaken from the roots, and the canes not shortened, while they were forced into growth in

February. In that brief statement lies a jumble of mistakes. The borders were made too rich by half, and are now in a “soapy” state. They were five times too large to commence with; the Vines having been shaken out ought to have been shortened considerably, and they ought not to have been forced. It was entirely a matter of chance that some of them made a good start, and now because the others did not these that did are made to bear beyond their capacity. This will bring things to a level no doubt, but it will be a low level, and this good vinery, which cost £300, will not be well furnished till new Vines are planted in a new border of sound fertile loam, narrow for a year or two, and firm. But this is not the time for details in border making. The lesson to be profitably learned is this. Those amateurs, we will say, who have planted Vines this spring without shortening the canes, and which are pushing pretty strongly from the top and trying to grow, but the lower buds starting weakly, then standing still, will fail in their object if they do not gradually remove the growths from the top downwards, one or two to-day, another or two to-morrow, till the root force, which is weak, is concentrated on a growth at or below the base of the rafters; then by maintaining a genial atmosphere, and not admitting air through the front sashes till the top ventilation fails to keep the temperature below 90°, a good cane may possibly be “run up” during the season; but it cannot be if the weak root force is frittered away through a multiplicity of outlets (buds), the weakness of the growths from which will be in proportion to their number. When newly planted Vines are stubborn or weak, there, then, is the remedy—reducing the outlets, and maintaining a moist rather than a dry atmosphere, through being chary of front ventilation till the canes get strong, then they may have air in abundance for ripening them.

Vinery No. 2.—Also nearly new, but the Vines cover the roof. The owner is their gardener in this case, and, like many another amateur, was afraid to thin both laterals and fruit. It is very evident the growths were overcrowded last year, hence the weak laterals this, and these when seen were far too numerous. The Vines are not 3 feet apart, yet there was an average of three laterals to each foot run of rod. The spurs are in places not more than 6 inches asunder, with, in most cases, two laterals from each, duly topped beyond the bunches, only one however from a spur bearing fruit, this bunch having been removed from the other because the owner of the Vines had read of that being a “good plan.” The plan is good enough in many vineries, but in this one there is only one right name for it—bad. With half the laterals removed the foliage would be too crowded and the Vines weakened instead of strengthened, for let it be clearly understood that a dozen imperfect leaves cannot compensate for the absence of one fully developed and capable of doing its important work.

The laterals should be so thinly disposed that the leaves on them can attain the full size of which they are capable without crushing against each other, or in other words there should be space between them so that glints of sunshine can pass through into the house. Let amateurs take that as a guide, and if the roots are duly supported, and the foliage kept fresh and clean, healthy Vines must of necessity follow, provided the serious evil of overcropping is avoided. In the case in question the gradual removal of superfluous growths went steadily on for a week, and now the Vines are in a fair way for maturing a good crop of fruit with an increase of strength for better work next year; had they remained unrelieved they would have been seriously injured before the end of the season, and next year's crop practically worthless.

When sufficient leaves are produced on the laterals for occupying the space at disposal, with a little to spare between them, all subsequent growths that push from the axils of the leaves should be pinched out as soon as they can be seized with the finger and thumb. It is not in the least necessary to pinch all these sub-laterals to the orthodox “one leaf;” this may be done with those starting from the

ower two or three joints for strengthening the buds there, to which the Vines will have to be pruned; but all axillary growths above them may be removed entirely, and if the main buds push pinch these too, and those below will be the stronger. This is a simple and safe way of preventing a good deal of overcrowding and concentrating strength in the main leaves, on which everything depends. It is not the practice generally taught, and the timid may hesitate to follow it, but it is safe and sound for all that, as any one may prove by a few experiments. It is not a tentative procedure with scores of good growers, and should be adopted by all when the laterals cover the roof rather more closely than is desirable, as is the case in the great majority of houses devoted mainly to the cultivation of Grapes.

Vinery No. 3.—This is a 20 feet long house with seven Vines in it, belonging to a clergyman and managed by a groom and gardener. He has managed them fairly well, the border outside, where the roots are, being thickly covered with manure. This is put on when the Grapes set every year and the loose raked off when they are ripe, an inch or two of fresh loam being then spread on the border. That was a new rule to me, and I am certain not a bad one. The Vines were in excellent health, but overcrowded, though the laterals were quite a foot asunder along each side of the rods. With such strong growth and large leaves the distance between the spurs should be 18 inches; but as this cannot be very well managed now the man was advised to remove all the sub-laterals except from the two or three lowest axils, also to only allow each alternate lateral to bear a bunch. As the crops will then average nearly or quite 2 lbs. to each lineal foot of rod it will not be bad, and in fact much better than if twice the number of bunches were allowed, as in this case the Vines would be overweighted, the Grapes not coloured, and shanking probably induced. But though there were many, too many, fine bunches, several of them were being spoiled, from a gardener's point of view, by rough handling in thinning. This was in progress and ought to have been finished, for it was difficult to insert the scissors between the berries without touching them—a sure proof of the work being too long delayed. The bunches thinned, moreover, had a shiny appearance, the result of rough handling, and too many berries had been taken from the tops of the bunches.

As the man appeared anxious to learn he was shown how to thin a bunch of Grapes. One was chosen that he was afraid to touch, as the berries were so small, yet they were fairly set, and that was enough. The berries stood quite clear, and it was easy to work the scissors between them. It was a fine bunch of the old favourite, the Grape of Grapes for grooms and gardeners and most amateurs—the Black Hamburgh. It would have been a symmetrical bunch and “tapering” but for a great shoulder jutting out from the top, half an inch above the rest, and half as long as the bunch itself. This was quickly cut off. The man picked it up and looked scared, but he could not put it on again, fortunately for the bunch, which the sprawling shoulder would have spoiled. It was a well set bunch, and fully two-thirds of the berries were cut out. A cedar pencil was held in the left hand for gently raising the shoulders, and snip, snip, snip went the scissors in the right, chiefly working under the shoulders and inside the bunch, no berries being cut out that had room to swell upwards and outwards. Only quite a few were taken from the upper side of the top shoulders, as it is surprising how the Grapes find room there, curling back and piling themselves, so to say, round the stalk; still, their probable size should be anticipated and room provided accordingly, though overthinning there is a common mistake, as is underthinning beneath and in the centre of the bunches. When the berries are as large as good-sized peas it ought to be easy to pass a thick pencil round them without touching, as the shoulders are held up for the purpose. When they fall into position this could not be done, but room is provided for their swelling all the same, and they may safely be left to occupy it and push their way into the best positions. Tying up the shoulders may be necessary

in the case of very large bunches of above 4 lbs., but a great deal of time is wasted in work of that kind on those that are smaller, and their appearance marred rather than improved. I wonder if Mr. Wm. Thomson of Clovenfords ties up the shoulders of his 10,000 to 20,000 fine bunches, but imagine he does not, and if his average is maintained growers may be satisfied. And this reminds that in many vineries in which I see the best Grapes Thomson's Vine manure is highly spoken of; but let it be said emphatically that the effects of the best manure ever compounded and the best soil that can be collected are quite nullified if overcrowding, overcropping, injudicious ventilating, and insufficient watering are permitted, that being the certain way to grow good crops of insects and bad crops of Grapes.

But a pause is imperative. If I were to describe the condition of the Vines in every garden entered during the past two months, and detail the routine that led to success or failure there would be no room for anything else in the Journal, and that would never do. The subject, however, may, perhaps, be resumed, and in the meantime if anyone desires a hint on any special point let him state his case; if he wishes to ask any questions let him ask them; if he prefers to grumble at anything that is said let him grumble, as it all does good in the end.—EXPERIENTIA DOCET.

SELECT ALPINE PLANTS:

ALPINE PHLOXES.

It is not many years since that the species and varieties figuring under this head were comparatively few in number, and while the species remain about the same to-day, the varieties have increased considerably, bringing with them new and pleasing shades of colour, while for free growing and flowering they are all that can be desired. These latter remarks apply more especially to the new varieties of setacea, which have enriched our gardens in spring to some considerable extent. The whole of the varieties of setacea, as well as frondosa, nivalis, and Nelsoni, form dense prostrate cushions, which in May and June are completely hidden by the numbers of flowers produced. Nothing can surpass them for effect in the spring garden, and where this is indulged in to any extent some of these Phloxes should be among the number.

For the convenience of those desirous of securing the most distinct varieties, I will give what I regard as the best, all points considered:—atro-purpurea, dark rosy purple, very free and a good doer; The Bride, pure white, with a ring of scarlet spots in the centre, a very telling variety, habit very compact, and an abundant bloomer. Compacta well bears out its name, and produces rose-coloured flowers freely. Vivid; in point of colour this is the most effective. It does not produce flowers as large as some, but is remarkable for freedom, while for colour it stands alone; its rigid tufts, studded with rosy scarlet flowers with deeper centre, render it very conspicuous. The foregoing I consider the best and most distinct of the forms of setacea, apart from which there are several which cannot be omitted. Among these Nelsoni stands first, and is covered with pure white masses of bloom, a most charming plant; and frondosa, with rosy pink flowers. All these are very similar in general aspect, quite hardy and most effective.

But what I regard as the gem of all the Alpine Phloxes is *P. amœna*. It is a most lovely plant in effect, and so continuous a bloomer, according to the season, it flowering in April or very early in May, and continues a long time in perfection. I have had this one in flower for six months, and had as fine flowers in October as in May; but to get this result it should be divided as soon as it has ceased flowering, and planted in good rich soil. Attend to watering and so forth, it will speedily recover, and show signs of flowering again. Its full height is 6 inches; the colour of the flowers a bright pleasing pink, and to see a bed some 40 feet long carpeted with this lovely plant and in full flower, is one of the prettiest sights in spring. The only other that calls for mention now is that usually sold as *verna*, but which correctly is *reptans*. It has also been distributed under the name *stolonifera*, but this species has bluish or slate-coloured flowers, while *verna* (*reptans*) has reddish-purple flowers. Both plants, however—*i.e.*, *stolonifera* and *reptans*, possess the same habit, hence the confusion probably. All the varieties of setacea and their allies may be increased by division, either in autumn or spring after flowering. Cuttings of all these taken when about 2 inches long—that is, of new growth and with a heel attached, root readily in moist sandy soil, in hand-lights or frames kept close and shaded. *Amœna* may be had in

plenty by division after flowering in May, while reptans will root readily if the runners are pegged on the surface of the soil, and may also be increased by division.

Every person who takes an interest in the cultivation of these plants should, I consider, take an interest in making the best possible display of them also. By this I mean that they ought not to be content by merely purchasing a plant and letting it do its best. That is not gardening in its truest motives, nor is it likely that the best results will be forthcoming for such scanty pains. Let all who grow plants make the most of the space at command, and few plants form a better starting point than these Phloxes. An amateur may buy one plant, and in three years it may make a nice tuft, but if he had put in say fifty cuttings each year in the manner I have described above, and only succeeded in rooting half of them, and potted them singly in small pots, what a grand stock of such things he may possess! But amateurs will wonder of what service such a stock may be to themselves, but I will explain. These Alpine Phloxes require to be seen in large spreading masses several feet across, and to quickly obtain these handsome floral carpets they should be increased freely. Established in small pots, and planted out about 6 or 8 inches apart each way, they would soon form a mass of colour such as is rarely seen, and make the garden a perfect paradise. Take Phlox Nelsoni and Vivid, and treat them as suggested, what a lovely picture they would make, especially if planted on a rocky surface, such as a rockery border; the effect would be natural and most pleasing, and by adopting this course throughout what a rich and varied display one could easily obtain by first ascertaining the best plants for such a purpose.

AUBRIETIAS.

Another group of easily grown Alpines are the Aubrietias. These, however, have been referred to so recently in the pages of the Journal by "A Londoner" that it would appear superfluous to say more. I cannot refrain from drawing attention to the happy result so clearly set forth in the illustration there given. Of two plants *Iris pumila cœrulea*, with Aubrietias nestling at its base, what more natural or what more beautiful than that charming combination, and yet but one of the many equally charming which may, and which really ought to be, of more common occurrence in our midst. After all it is not an endless variety which gives the effect, but the few carefully studied and judiciously blended together.—J. H. E.

ORTON HALL.

ORTON HALL, about two miles from Peterborough, is the seat of the dowager Marchioness of Huntly, a great lover of plants, who has collected many hardy species on the Alps and elsewhere for establishing at home. The rockeries and borders are filled with hardy flowers, and the grass, where the lawn is not closely machined, is in places full of bulbs. When these push up in myriads in the spring, followed closely with hardy Orchises, which abound, a stroll round the semi-dressed grounds is very enjoyable. The grounds are, however, always "furnished," and are perhaps never more beautiful than when the numerous and fine Conifers are wreathed with fleecy snow, or resemble fountains and cones of silver by the hoar frost glistening on every spray and leaf. The late Marquis of Huntly was a great planter, and as the soil is good most of the trees have made splendid growth, and Conifers are thus the commanding feature of Orton.

When going north a few weeks ago on a visit to Belvoir it may be remembered I called on Mr. Harding, the gardener, and we spent a few pleasant hours among the Conifers, ascertaining the heights of some in a very simple and certain manner. As the plan adopted may be worth making more generally known, a sketch of the home-made appliance is given in fig. 1. Mr. Harding's tree measurer on the right of the figure consists of a staff 6 feet long pointed for pressing into the ground. To the centre of the staff a piece of half-inch board 12 inches wide and exactly square is affixed with screws. The diagonal cross lath is 3 feet long and perfectly straight. It may be fixed or moveable; if the latter, a small batten being screwed on the board for it to rest on when in use. The plumb line is indispensable, as no correct measurement could be had without it. The plumb-bob may be about the size of a small walnut, the string passing through its centre, then knotted to make all secure.

In measuring the tree the staff is placed at a distance from it so that with the plumb exactly perpendicular, the cross lath points to the top of the tree, the person taking the "sight" resting on one knee or reclining to bring the eye to the bottom of the lath. The lath is then drawn to the ground, where the end rests at C in the figure, or if the lath is fixed a string will answer the purpose of extending the sight line to the ground. From this point C to the centre of the trunk, not the face of it nearest the point, but the middle, will represent the actual height of the tree; or to put the matter concisely, the horizontal line, AC, is equal to the vertical AB; and if the tree were blown or cut down its top would follow the course shown by the curved line and rest at C. If a tree has several leaders, as *Pinus excelsa* and some others often have, the sight should be taken of the most central one, or

nearest in perpendicular with the root of the tree, not a side branch that may happen to be a little taller, as the base line would then not give the true height of the specimen. On level ground it is easy to perceive that altitudes of a number of trees can be quickly ascertained. When the ground is irregular provision must be made for having the line level from the root of the tree, or A in the figure to C. The central board, it may be repeated, must be a true square, the perfectly straight sighting lath resting across it exactly from corner to corner, as the least deviation will lead to error, and the weight must hang positively plumb, as not otherwise can the measurement be accurate. Any handy man can make an appliance of this kind—at least Mr. Harding made the one that answers its purpose so well.

The sizes of a few of the Orton Conifers may now be given. *Pinus Jeffreyi*, several specimens, foliage a foot long, and straight trunks, the tallest 60 feet in height, girth 6 feet 3 inches. *Wellingtonia gigantea*, several over 60 feet high, the tallest 67 feet, girth 14 feet 6 inches, produces cones in abundance, but as yet no fertile seed. *Abies cephalonica*, 55 feet high, and 5 feet 6 inches in girth. *A. Pinsapo*, 57 feet high, 7 feet in girth, a good specimen. *Abies Nordmanniana*, 53 feet high, 5 feet in girth, a beautiful tree, and has produced plenty of cones with seeds about 10 per cent. fertile. *A. bracteata*, 39 feet high, 5 feet 3 inches in girth, a noble looking tree. *A. amabilis*, beautiful foliage, resembling *A. Nordmanniana*, but more dense and silvery beneath, 34 feet high, and 4 feet in girth. This species has not yet produced cones. *A. Morinda* (syn. *Smithiana*), with weeping habit, 51 feet high, and 5 feet girth. *A. Douglasi*, 65 feet high, 7 feet 6 inches in girth. *A. lasiocarpa* (syn. *concolor*), a grand specimen, feathered to the ground, 54 feet high, with trunk 7 feet 9 inches in girth, one of the best. *A. grandis*, 60 feet high, and 6 feet 3 inches in girth. *A. pectinata*, the common Silver Fir, 85 feet high, and 13 feet in girth, an old tree. *A.*

FIG. 1.—MEASURING TREES.

nobilis, 40 feet high. *A. magnifica*, 10 feet high, with glaucous foliage in the way of *nobilis*, but distinct from that beautiful kind. *Cedrus Deodara*, 44 feet high, with a good trunk, 7 feet 6 inches in girth. *C. atlantica*, a beautiful specimen, with glaucous foliage 56 feet high, and 8 feet in girth, produces handsome cones in abundance. Cedars of Lebanon are also good, about 60 feet high.

Libocedrus decurrens (known as *Thuja gigantea*) is represented by handsome specimens, the tallest 48 feet high, 6 feet 4 inches in girth; small cones produced some years in abundance with fertile seed. *Pinus excelsa*, distinct, 59 feet high and 9 feet 3 inches in girth, has produced good seed. *P. Sabiniana*, 55 feet high and 7 feet 9 inches in girth. *P. macrocarpa*, handsome foliage, 51 feet high and 8 feet in girth. *P. ponderosa*, 60 feet high, very straight trunk, 5 feet 8 inches in girth. The red male catkins are very showy in June. *P. Laricio*, 57 feet high and 8 feet in girth; produces good seed. *Taxodium sempervirens*, 66 feet high and 12 feet 6 inches in girth. *Salisburia adiantifolia*, 32 feet high and 3 feet 6 inches girth. *Cupressus Lawsoniana*, a good specimen, 38 feet high; produces good seed freely. *C. macrocarpa*, 57 feet high and 8 feet girth; produces good seed. *Thujaopsis borealis*, 40 feet high, a distinct and handsome tree. *Torreya myristica*, a tree with curious fruit about the size of a walnut produced some years in abundance, 18 feet high, 60 feet circumference spread of branches; a quantity of young trees has been raised from this plant. *Thuja gigantea* (also known as Lobbii), Lobb's Arbor Vitæ, 48 feet high; a tree that thrives well, producing trunks as straight as an arrow, handsome foliage, useful for decoration; healthy plants make 3 or 4 feet leaders in one season; produces good seed abundantly, from which many hundreds of young trees have been raised, some of the best at nine years old being now 15 feet high. This is the yellow Cedar of the settlers of British Columbia and N.W. America; its timber is good and fine grained, and Mr. Harding regards it as the timber tree of the future for this country. It should be added that all girths were taken at 1 foot from the ground.

There are numerous other specimens of various Coniferæ, a good

plant of the Irish Yew, *Taxus baccata* var. *fastigiata*, *T. adpressa*, *Biota pendula filifera*, 18 feet high, pendulous, and very distinct. *Juniperus chinensis*, *J. excelsa*, *J. excelsa stricta*, *J. squammata*, an old plant, spreading low bush, not exceeding 3 or 4 feet in height. *Cupressus sempervirens*, *Thuopsis dolabrata*, *Pinus cembra*, *P. Strobus*, and old Scotch Pines. Sufficient has been said to show the noteworthy character of the Orton Conifers, except that a few words must be devoted to the Wellingtonias. Though in the above list the height of the tallest specimen is given as 67 feet high, 14 feet 6 inches girth, there are many over 60 feet in height. All were raised from seed on the place. In the avenue and about the grounds there are upwards of 300 specimens. They were planted in 1860 and 1861, the plants being at the time 3 or 4 feet in height. The Wellingtonia avenue is 36 feet in width, with a gravel drive up the centre 12 feet wide, the trees being set 30 feet apart. Its length in a straight line or view is 700 yards, containing about 140 trees, but a continuation of this drive at one end to the right hand, and another at the other end to the left hand, makes it over a mile in length, but Wellingtonias are not planted all the way. One of the best furnished and symmetrical trees stands by itself on the lawn near the rockery, and is now 57 feet in height, and by its vigorous annual growth promises to make the best tree in the grounds. This and many others have been invigorated by heavy top-dressings of manure and soil. Some of the trees have grown with much greater freedom than others, the latter having presumably been raised from cuttings, the former from seed. Plants from *Thuia gigantea* raised from cuttings by Mr. Harding do not approach in freedom of growth others raised from seed, though he knows which cuttings to select for making the best trees. It may be added the timber of Wellingtonias is of practically no value, several large trees having been cut down at Orton, but the wood is spongy and destitute of durability.

The rockbound dells and wilderness ferneries are extensive and picturesque. The are embowered in foliage and delightfully cool in sultry weather. On some of the large moss-covered boulders seeds have fallen from trees of *Thuia gigantea* above and freely germinated, and one tree clinging to the perpendicular face of the rock is 4 or 5 feet high. It is secured in its position, and has a singular effect. The roots have extended in the moss to the ground, and the tree is thus established. A large rockery has been made in the open for alpine and other plants suitable for the position, about 700 species are growing at present. A small Italian garden with clipped Yews adjoins the mansion, to which is attached an elaborately built conservatory, and the parish church with its ivy-clad tower is only a few yards distant, and is an interesting feature of the beautiful grounds. There is a large and excellent kitchen garden of four acres excellently managed, vegetables and fruit being abundantly produced. Grapes, Cucumbers, and Tomatoes are well grown, also plants for decorative purposes, and a fine *Marchal Niel* Rose will be referred to on another occasion. Mr. Harding is a practical and industrious gardener, and a credit to the craft to which he belongs.—A LONDONER.

CYCLAMENS AT BESBOROUGH COURT, CORK.

CYCLAMENS are too seldom seen well grown in gardens, and it is a pity they should be so greatly neglected, as their usefulness in the winter and spring months is beyond question. These plants have been of a very interesting character here for the last two years, being greatly admired by many visitors. A span-roof house is devoted to them, and the treatment is as follows:—After flowering they are removed to a cool house. We do not adopt the general system of drying, but just keep them in an intermediate state. They remain in this position until the middle of August, when they are shaken out and repotted. The compost given consists of eight parts of loam shaken out, one-third of peat, and a third of leaf mould, with a liberal dash of coarse sand; also adding a 3-inch potful of soot and the same quantity of fish manure to every bushel of soil, mixed thoroughly.

We sow seed every year, because we discard all plants that are over two years old. At this age we find no difficulty in getting them to start, whereas plants three and four years old often are very stubborn in starting. The pots mostly used are 6 inches in diameter. Some were placed in 8-inch pots; they certainly made very fine plants, but they did not flower any better than those in the 6-inch pots. I counted on several plants in the latter size over 160 flowers fully expanded.

The place for starting is a cold pit; there we have a little fermenting material, just enough to cause a slight bottom heat. On this they are placed, then supplied with tepid water, after covering the crowns with a little sifted leaf mould, which keeps them cool and moist all through the starting period, assisting growth. This pit is shaded from hot sun, providing just a chink of ventilation when the temperature rises to 75°, syringing and closing about 8 P.M. As the leaves appear through the leaf mould it is removed from the surface of the pot. Then the plants are shifted to a cold frame, standing them on pots to prevent worms or any insects entering the bottom of the pots. More air is given then to obtain sturdy plants, closing with a little sun heat in the afternoon. As the evening approaches the lights are thrown off if there are no prospects of rain, as the dew seems to be very beneficial to them. By the end of September the pots are washed and staged in the flowering house. Ventilation is then provided according to the weather, damping between the pots and misting the plants over the foliage on fine days. As the flowers become visible a little artificial heat is given, keeping ventilation on constantly day and night. By that means the plants do not become drawn, and a circulation of air prevents the flowers

damping, which they are very liable to do. The temperature at night never exceeds 50° to 55°, with a rise of 5° by day.

The watering is a very important point to be taken into consideration. If the soil is allowed to become dry the plants will lose all their flowers, whereas, on the other hand, if kept too wet they lose their roots; then the least exposure to sun causes the foliage to flag. They are subject to the attacks of thrips, and we use a little tobacco powder applied with a distributor and syringed off the next morning.—FOREMAN.

REPORTS OF SHOWS.

As it is impossible to make special arrangements for reporting all the shows that will be held during the present month, we shall be obliged by receiving as early as is convenient brief accounts, with the results in the leading classes, from secretaries of societies or friends who may visit exhibitions in various parts of the country, and a previous intimation as to when the notes may be expected would assist us materially. Long newspaper reports of local shows and complete lists of prizewinners cannot, as a rule, be inserted. The general character of the exhibits, with particulars of the chief classes, are preferable to the majority of our readers. When more than one report is sent of a show, as occasionally happens, that which arrives first is usually inserted.

ROSE SHOWS IN 1888.

- July 5th.—Bath, Farningham, and Norwich.
- " 6th.—Sutton.
- " 7th.—Crystal Palace (National Rose Society).
- " 10th.—Gloucester, Ipswich and Oxford.
- " 11th.—Ealing, Glasgow, and Tunbridge Wells.
- " 12th.—Birmingham, Carlton-in-Lindrick, and Winchester.
- " 14th.—Eltham, Manchester, and New Brighton.
- " 16th.—Christleton and Newcastle-under-Lyme.
- " 17th.—Leek and Ulverstone.
- " 18th.—Birkenhead.
- " 19th.—Helensburgh.
- " 20th.—Darlington (National Rose Society).
- " 24th.—Tibshelf.

In the case of Birmingham and Glasgow, where the show extends over two days, the date of the first day's exhibition only is given.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

AMATEURS AND TRADING.

JUST as the war of the Roses is commencing, I hear that strife has broken out amongst the members of the N.R.S. in consequence of one of the leading amateurs having sold a large quantity of Roses, and I fear he cannot say it is the first sale. Let us hope the Committee will at once sift the matter to the bottom, otherwise the N.R.S. is doomed.—AMATEUR.

ROSES AT KETTERING.

AT the annual Show held on the 2nd inst. cut Roses were the leading feature. In the class for forty-eight blooms Messrs. G. & W. Burch, nurserymen, Peterborough, were first, their stand containing some very fine flowers indeed, such as *Marie Baumann*, *Queen of Queens*, *Marquise de Castellane*, *Mdlle. Marie Verdier*, *Grace Darling*, *A. K. Williams*, *Sunset*, *Captain Christy*, *Mdlle. Marguerite D'Ombraïn*, *Camille Beruardin*, *Madame Gabrielle Luizet*, *Madame Lacharme*, *Madame Bravy*, *Niphetos*, *M. Noman*, *Ulrich Brunner*, *Perle des Jardins*, *Lady Mary Fitzwilliam*, *Magna Charta*, &c. Second, Mr. W. H. Frettingham, nurseryman, Beeston, Notts; third, Messrs. W. & J. Brown, Wolthorpe Nurseries, Stamford. Mr. John House, nurseryman, Peterborough, entered for competition, but through losing the train did not reach the Show until after the awards were made. He had some very fine blooms, and a box of William Allen Richardson finely coloured, a variety he grows with great success. In the class for twenty-four varieties Mr. H. Watt, gardener to G. L. Watson, Esq., Rockingham Castle, won first with fairly good blooms, but all unnamed. Mr. Watt also had the best twelve Tea and Noisette Roses, also without names. The best twelve Roses shown by amateurs came from Mr. Alfred Warner, Pytchley, they also being unnamed. In the class for six varieties of Tea Roses the Rev E. Gates, Pytchley, was first with good blooms of *Madame Bravy*, *Souvenir de Gabrielle Drevet*, *Madame Lambard*, *Jean Ducher*, *Catherine Mermet*, and *Souvenir d'un Ami*. Second, Mr. A. Warner. Special prizes for Roses shown by amateurs and cottagers were offered by Messrs. W. & J. Brown, also by other gentlemen.

BROCKHAM.

ON Thursday, June 28th, the Brockham Amateur Rose Association held its twenty-third Show of Roses in the grounds of Holmwood Park. This is the fourth time that Mrs. Gough Nichols has invited the Association to partake of her hospitality, which on this occasion was of a particularly generous character. Adjoining the large marquee where the Show was held, a long tent capable of seating between two and three

hundred persons had been erected, with a carpeted wooden floor, a roof impervious to rain, and the walls fitted with windows and curtains, and lined throughout with chintz of a very tasteful pattern. In fact, it was a very pretty little theatre, and on the platform at one end Mr. Grossmith, from the Savoy, gave several well-known and very amusing sketches. A very large and appreciative audience was present, in spite of the heavy rain, and had it not been for the weather the room would scarcely have held the many friends whom Mrs. Gough Nichols had invited to witness the entertainment. At the other end of the room the Hungarian Band, which had also been engaged, played a selection of their well-known and beautiful stirring music from time to time during the intervals of Mr. Grossmith's entertainment. The house was, with a kindness characteristic of Mrs. Gough Nichols, thrown open to her friends, and every kind of refreshment was provided. A particularly pleasing effect was produced by the removal of the doors throughout the long corridors, and different sorts of Iris and other flowers with drooping Grasses being suspended in pieces of bamboo. The house, accordingly, which is filled with very many plants of beauty and value, was occupied by a continual stream of visitors.

Holmwood Park is three miles from Dorking. It was formerly the residence of Francis Seymour Larpent, Esq., Judge Advocate-General to the Forces in the Peninsula of Spain, under the late Duke of Wellington. It was subsequently purchased from Baron de Hochfeld Larpent by the late John Gough Nichols, Esq., F.S.A., who for many years was the editor and proprietor of the "Gentleman's Magazine," and the author of numerous antiquarian treatises.

The house (which, by the way, is roofed with Horsham flags) stands in the most beautiful and picturesque part of Surrey near Leith Hills and Holmsdale. In years gone by it joined the extensive woods of the Duke of Norfolk, which reached as far as Arundel Castle. Designed and built by Mr. Larpent, it was formerly a warder's lodge belonging to the Earls of Arundel, and is now surrounded by a park-like common of 800 acres. The church, built and endowed by Mr. Larpent, stands on the hill above, and there are beautiful views in the distance of the Reigate Hills on one side and the Redland Woods on the other.

The Rose Show was held in a meadow opposite the house. There are sixty-two members of the Association, and of these twenty were exhibitors, two more than last year. Considering that Rose-growers hitherto have this season been discouraged by nearly every plague that the "queen of flowers" is heir to, it was no small surprise to see such a large Show and such a good one. It helped the attractiveness of the Exhibition to see at the entrance a grand box of thirty-two new and other Roses from the well-known gardens of Messrs. George Paul & Son of the "Old Nurseries," Cheshunt, containing Mrs. John Laing, Madame Bois, three red seedlings (raised by Mr. Geo. Paul from Beauty and Grandeur of Cheshunt), Lady Alice, Inigo Jones, Comte de Paris, Madame Honoré Defresne, Lady Helene Stewart, Silver Queen, all new, and the following:—Madame Treyve, Marie, Château des Bergeries, Lady Mary Fitzwilliam, Souvenir de Gabrielle Drevet, Madame Henry Pereire, Gloire Lyonnaise, and American Beauty. In addition to these Roses, Mr. Appleby of the Boxhill nurseries had, as he always does, brought very many decorative plants, such as Caladiums, Crotons, Dracænas, Ferns, and Pelargoniums, which made the Show tent very bright, and two boxes of H.P.'s and Teas, comprising amongst others, Souvenir d'un Ami, Niphotos, Rubens, Clotilde, and Madame Welch, Ulrich Brunner, Xavier Olibo, H. Schultheis, Madame G. Luizet, and Général Jacqueminot. Mr. E. Claxton of The Rosery, Allerton, Liverpool, had also actually sent his man with two grand boxes of Teas, not for competition, including Anna Ollivier, Souvenir de T. Levet, Jean Ducher, Innocente Pirola, Madame Lambard, Madame de Watteville, and Francisca Kruger. The three Judges were T. W. Girdlestone, Esq., on the Committee of the N.R.A.; Mr. George Paul, from the Old Nurseries; and the Rev. A. B. Alexander, late Hon. Sec. of the Farnham Rose Association, and they were unanimous generally in awarding the prizes as follows:—

For twenty-four distinct blooms (three competitors), first prize, gold medal of the N.R.A., awarded to the Rev. Alan Cheales for a fine box, including Star of Waltham, Princess of Wales, Duke of Edinburgh, Marquise de Castellane, Violette Bouyer, Charles Lefebvre, La France, Glory of Cheshunt, Belle Lyonnaise, A. K. Williams, Lady Mary Fitzwilliam, Pride of Waltham, Reine Marie Henriette, Maréchal Niel, Madame Thérèse Levet, Jean Ducher, Le Havre, Rêve d'Or, Fisher Holmes, Dupuy Jamain, Madame Bravy, Duke of Teck, Catherine Mermet, and Horace Vernet. The second prize for 24's went to Mr. Cuthell for a good box containing, amongst others, Magna Charta, Captain Christy, Etienne Levet, M. Noman, Countess of Rosebery, M. E. Y. Teas, Madame Gabriel Luizet, and Abel Carrière. Mr. F. T. Wollaston also had a good box in this class, which did him credit.

For twelve Teas in class 2, Mr. Cuthell took first prize (silver medal of N.R.A.) for Jean Ducher, Marie Van Houtte, Catherine Mermet, Anna Ollivier, Princess of Wales, Souvenir d'un Ami, Rubens, Madame Lambard, Perle des Jardins, Madame Watteville, Jules Finger, and Caroline Kuster. The second prize (bronze medal of N.R.A.) was won by Mr. Horne for Perle des Jardins, Madame Bravy, Maréchal Niel (grand bloom), Anna Ollivier, Climbing Devonensis, Madame Camille, and other varieties. The Rev. A. Cheales was highly commended by the Judges for a very good box. For nine single trusses Teas, N. or H.P.s (same kind), Mr. Cheales won the first prize for Maréchal Niel, and Mr. Horne was second for Annie Laxton. For four triplets, the Rev. Alan Cheales had the first prize for Violette Bouyer, A. K. Williams,

Lady Mary Fitzwilliam, and Reine Marie Henriette. The second prize went to Mr. Cuthell.

In division B, class 1, for twelve single blooms, distinct, Lady Lawrence won the N.R.A. gold medal for twelve very fine blooms of Lady Mary Fitzwilliam, Earl of Pembroke, Edouard Morren, Jean Pernet, A. K. Williams, Anna Ollivier, Marie Baumann, C. Bell, Général Jacqueminot, Eugène Furst, Madame M. Roederer, and M. Noman. Mr. Thompson took the second prize, and in her box was a fine bloom of Sultan of Zanzibar. The Hon. Lady Ryder was highly commended. For six distinct blooms of any sort Mr. Leopold Seymour received first prize, and Mr. Hatch second. For six of the same sort of any class of Rose Mrs. Mortimer carried away the first prize for Souvenir d'un Ami, and Mrs. Thompson second prize for the same Rose. In the class of three triplets Mr. Leopold Seymour had the first prize, and Mr. Hatch second.

For the decorations in division C there were altogether sixteen exhibitors. Mr. Cuthell won the first prize for a dinner table decoration of Tea Roses and Ferns that was well arranged and in excellent taste. Mr. Bruce Nichols took second prize for two low baskets, well arranged, but with too much Fern. For the drawing-room decorations, which displayed both good taste and genius, Mrs. Benecke had the first prize for a ball wicker basket, containing Spiræa, Aquilegia, Fern, and Passion Flowers, and Begonia. For a pretty simple arrangement of pink Pelargonium, Fern, and white Geranium, Mrs. Bruce Nichols received the second prize, while for a very large arrangement in Pæonies and Copper Beech Miss Perkins took equal second prize. The buttonhole bouquets were prettier and more tasteful and suitable than usual, though some were too small and others too large. Mrs. Cuthell, Mrs. Thompson, and Miss Carter Perkins took the first, second, and third prizes respectively.

For the first time for twenty-three years the Treasurer could not attend the Show. His absence was greatly felt, and the fullest sympathy went with him. It only remains to say that—1, The Show was an exceedingly good one. 2, The Teas were unusually well represented. 3, All the classes had a fair number of competitors. 4, The old winners did not have it all their own way. 5, The number of visitors was very large. 6, The luncheon to the Committee unusually good; 7, and the speeches of the three Judges thereat were short and to the point.—A. B. ALEXANDER.

RYDE.—JUNE 28TH.

THE fourth annual Exhibition of cut Roses and other flowers was held in the Town Hall, Ryde, Isle of Wight, on Coronation Day, June 28th. The day is observed as a general holiday throughout the Island, and, notwithstanding the many counter attractions, and the inclement weather, the Exhibition drew together a large number of visitors, who seemed to take a lively interest in the excellent display of flowers. The Exhibition was opened by the Mayor (R. Colenutt, Esq.), accompanied by other members of the Corporation, and Mr. J. Eley, the efficient and courteous Hon. Secretary. The wet weather the day previous and on the morning of the Exhibition no doubt prevented many from taking part in it; nevertheless, it was satisfactory to find that the exhibits, in number and quality, were quite equal to those of the previous year, and much better than we expected to see in this late and unfavourable season.

In the open class for twenty-four cut Roses, distinct, the first prize, a gold medal offered by the National Rose Society, was won by Mr. R. E. West, Reigate; and the second prize, the silver medal of the N.R.S., was awarded to Messrs. W. & G. Drover, Fareham. The first prize stand contained good blooms of M. E. Y. Teas, Countess of Rosebery, Marquise de Castellane, Marguerite Brassac, Mrs. Baker, &c.; and in Messrs. Drover's stand were good blooms of Pitrod, a good dark Rose, Cannes la Coquette, Souvenir de René Lévêque, Duchess of Hatwell, Rosy Morn, Mrs. Laxton, &c. Messrs. Ewing & Co., Havant, also exhibited in this class. In the class for twelve, Captain Ramsay, Fareham, was first with good blooms of Earl of Pembroke, Merveille de Lyon, Lady Mary Fitzwilliam, Souvenir d'un Ami, and Amazone, a beautiful yellow Tea. The second was awarded to Mr. D. Seaton, Bitterne. The stands of Tea Roses were very fine, Mr. D. Seaton winning first honours for twelve, showing Grace Darling, Madame Lambard, Rubens, Madame Cusin, very fine. Second, Mr. Ridout, Woodhatch Gardens, Reigate; and Messrs. Ewing & Co. were highly commended.

The chief competition in the local classes was for two silver challenge cups presented by the Rev. Canon Girdlestone, and offered as the first prize in the twenty-four, and the first prize in the twelve class, both of which have now been finally won by Mr. G. Pack of Ryde, whose exhibits were amongst the finest in the Show. In the class for twenty-four there were five competitors, and in Mr. Pack's winning stand were good blooms of Glory of Cheshunt, Violette Bouyer, Dupuy Jamain, Marie Baumann, Isaac Perrière, Chas. Lefebvre, Mrs. Baker, and Madame Victor Verdier. Mr. J. O. Brool, Ryde, also exhibited well, President Vallamy and Ulrich Brunner being very fine. In Mr. Pack's winning stand of twelve blooms were good examples of Mrs. Caroline Twalles, Violette Bouyer, Merveille de Lyon, and La France. Mr. Brooks was again a good second in this class. Mr. Pack was also first in another class for twenty-four distinct varieties, with Mr. E. Ratcliffe, Ryde, second. In the leading stand were good blooms of Madame Marie Finger, Lady Mary Fitzwilliam, Duke of Edinburgh, and Mrs. Baker. With twelve Teas, four varieties, Mr. G. Williams, Gatecombe, was first, and Mr. Brooks a close second; and in the class for six Teas, distinct, were some fine blooms of Grace Darling, Madame Willermoz, Madame de Jacquier, Jules Finger, Maréchal Niel,

and Reine Marie Henriette, exhibited by Mr. Pack and awarded the first prize.

The baskets of Roses, as well as the baskets of miscellaneous flowers, are always a strong feature in the Isle of Wight exhibitions, and in this instance were no exception to the rule. They are usually of a large size, measuring 2 feet or more in length, and about 1 foot to 1 foot 6 inches across, the cross handle being decorated with flowers and foliage according to taste. The first prize for a basket of cut Roses was awarded to Mr. H. Strickland, Shanklin, for a good basket well arranged and of splendid quality. The second went to Mr. J. Atrill, gardener to E. Ratcliffe, Esq., Ryde; and Mr. J. Coffin, gardener to Sir Henry Daley, was highly commended for a basket showing much taste in the arrangement. For a bouquet of Roses, Messrs. W. & G. Drover was well to the front with a beautiful basket of Teas and Moss Rose buds. For a box of Roses Mr. J. Atrill was first with a large box of blooms; Mr. Darebury second. Messrs. Ewing & Co. and Mr. Brooks also exhibited well.

Miscellaneous.—For a basket of cut blooms Mr. Atrill had a very beautiful arrangement, containing Water Lilies, Roses, Gloxinias, Pelargoniums, &c., and was awarded first; Mr. J. Woods, Ryde, second; Mr. J. H. Sharland, Newport, h.c. For a hand bouquet, Messrs. W. & G. Drover was awarded first for a choice arrangement of Gardenias and Stephanotis, Mr. J. Atrill, second; and for six buttonhole bouquets Mr. J. Atrill was a good first, with Messrs. W. & G. Drover second. Boxes of cut Pelargoniums, Zonalas and show varieties, Pyrethrums, single and double, in their several classes were well represented, and made a fine display of colour, a noticeable feature being a fine collection of cut herbaceous flowers, containing some very fine Pæonies from Messrs. W. & G. Drover, which gained the first in that class. The table decorations and other cut flowers exhibited by the ladies in their various classes showed much taste in arrangement, Miss M. Shaw, Mrs. E. F. Brook, and Mrs. Jones being the most successful. Two very fine dishes of Strawberries (James Veitch) from the open air were exhibited by Sir Henry Daley's gardener, and in the several interesting collections and baskets of wild flowers, was some very fine examples of the Butterfly, Bee, and Fly Orchises.

REIGATE.—JUNE 30TH.

THE late Mr. Mechi of "magic strop" and Tiptree fame once enunciated the formula,

"A dry May, and a dripping June,
Does surely bring all things in tune."

His maxim will be tested this year. May here, in mid-Surrey, had but four wet days, while June is ending with sixteen and a rainfall of all but 4 inches; at Brockham Vicarage 3.91 inches, at Reigate 4.93 inches. The hapless hay mourns, but the Rose plants rejoice, and the blooms that can struggle out on sunny moments are excellent. High authorities foretell a good though late Rose season. The Show of Roses at Reigate on June 30th was of a nature to confirm this anticipation. The Roses had a cool morning for travelling and a bright breezy afternoon in which to be admired. The Show was small, and many blooms showed marks of weather.

The awards were as follows:—For thirty-six varieties.—First, Mrs. Waterlow; second, Mr. T. B. Haywood. Twelve triplets.—First, Mrs. Waterlow. Only one box shown. Eighteen Teas.—First, Mrs. Waterlow. Again only one box. Twenty-four varieties.—First, Mr. A. Slaughter; second, Mr. R. West; third, Mr. E. M. Bethune. Six triplets.—First, Mr. R. E. West; second, Mr. F. C. Paule; third, Mr. A. Slaughter. Twelve Teas.—First, Mr. A. Slaughter; second, Mr. E. M. Bethune; third, Miss Baker. Twelve varieties.—First, Mr. E. Wilkins; second, Rev. Alan Cheales; third, Mr. C. E. Cuthell. Four triplets.—First, Mr. E. Wilkins; second, Rev. Alan Cheales; third, Mr. E. Horne. Six varieties. First, Mr. E. Wilkins; second, Mr. E. Mawley; third, Mr. Freshfield. The Committee have failed to protect this last small class against those who show in twelve, a mistake they will do well to remedy.

Mr. Haywood showed a fine Mrs. J. Laing, a Rose of Bennett's, which is growing in favour. Mr. Slaughter's Général Jacqueminot was remarkable. Mrs. Waterlow showed Pride of Reigate, fine, and in all its pride of place. The Show would have been a small affair but for the kind assistance of the trade. Mr. G. Paul came to judge, and brought a box of Roses; one very pretty carmine Rose, not yet named, seedling, also Lady Alice, his white sport from Lady Mary Fitzwilliam, and Luciole, a new Tea of great beauty. Mr. Rumsey had a box of high-class Roses; Mr. Bunyard the same, and also a most interesting collection of twenty varieties of garden Roses. It has been strongly pressed upon the Brockham and Reigate Committees that they should have a class in future shows. Messrs. Cheal & Sons exhibited some beautiful cut flowers; but the great feature of the day was a lovely set of seven boxes of Teas brought by Mr. Prince of Oxford, in one case Madame Cusin and Maréchal Niel being shown together most effectively. His new pure white sport (H. S. Prince) from Souvenir d'un Ami shown side by side with the parent Rose excited great admiration. It is very like Niphetos, but larger and more robust, and likely when in commerce to be in great demand.

The Judges were Messrs. G. Paul, Rumsey, Prince, Brown, Ridout, and Rev. A. Cheales. The President of the Association and Mr. Hayward entertained the Committee, Judges, and other friends with the splendid hospitality for which Reigate Presidents have always been

famous. It cannot be doubted that these social gatherings tend to develop and perpetuate the friendly feeling and generous rivalry amongst competitors which is almost invariably conspicuous on these occasions. A basket of blooms from a new Scotch stock of seedling Briars, exhibited by Mr. Wollaston, also excited attention, giving promise of an excellent stock of the future. This is likely to be on show again at the N.R.S. Crystal Palace Show. The wild Rose now, wedded to our high-born Teas, receives an attention, which the Wizard of the North seems to have anticipated, but to deprecate—

"Cherish the Tulip, prune the Vine,
But feely let the Woodbine climb
And leave untrimmed the Eglantine."—(Marmion.)

—A. C.

ANOTHER correspondent also favours us with the following note on the above Show:—"Previous to the Show day the Secretary and Committee must have had a most anxious time, by reason of the general backwardness of the season and the unpropitious state of the weather, the neighbourhood having suffered for several days recently from violent thunderstorms with heavy downpours of rain and hail, the latter in some places completely riddling the leaves of the Roses as though they had been pierced by bullets, while in the course of five hours, on the 26th ult., nearly 1½ inch of rain was registered, this being frequently followed by heavy showers up to the morning of the Exhibition. No rosarian need be told what a disastrous effect this had on the Roses, more especially the Teas, and delicate petaled ones, such as Lady Mary Fitzwilliam; consequently the falling off in the leading classes was very noticeable, while the Great Doods Roses had it all their own way, being cut on the spot. Among the amateurs rough, coarse, and damaged flowers were in the ascendant, but the two best stands were in the class for twenty-four, distinct, shown by Mr. Slaughter, Steyning, and R. E. West, Esq., Reigate. These were remarkably fresh, clean, and very even, and only a few points divided them. Mr. West is showing well this season, having already staged, at different shows, eleven stands, and secured nine prizes. This is a great achievement for one with such a limited quantity of Rose trees. Mr. Prince sent a lovely and pure white sport from Souvenir d'un Ami, named Souvenir de H. S. Prince. It is a more pearly white than the old Niphetos, which some thought it closely resembled—though the distinction is great by reason of the petals being stout, solid, and erect. Unquestionably this is a Rose that will be much sought after, as in addition to its other good qualities, it has the robust and hardy constitution of the parent."

CROYDON.—JULY 4TH.

A SATISFACTORY Show was held in the grounds of Brickwood House, East Croydon, on Wednesday last, and it was the general opinion that both in number and quality there was a decided improvement on the previous exhibitions of this Society. Two large tents were occupied with the principal exhibits, comprising specimen plants and groups, with a good display of cut Roses, and some fruits.

A special feature in the Rose classes was the trophy, value twenty-five guineas, offered to gentlemen's gardeners and amateurs for thirty-six distinct Roses. The trophy is to be held by the winner for the year, and if won by the same exhibitor twice consecutively it will become his property. With it was also offered the National Rose Society's gold medal. It might have been expected that such inducements would have brought more than two competitors; but both these—namely, R. E. West, Esq., Reigate, and Alfred Slaughter, Esq., Jarvis Villa, Steyning, showed extremely well. So close were the competing stands that it was only after long and careful examination that the award could be made, and it was eventually given in favour of Mr. West. His blooms were larger than those of his opponent, but hardly, perhaps, so fresh and neat.

The varieties represented were as follows—Back row: Duke of Edinburgh, Pride of Waltham, Duke of Teck, Madame Gabriel Luizet, Charles Lefebvre, Général Jacqueminot, Madame Isaac Perrière, Dupuy Jamain, Duchesse de Morny, Madame Victor Verdier, La France, and Etienne Levet. Middle row: François Michelin, Dr. Andry, Comtesse d'Oxford, A. K. Williams (a splendid bloom), Heinrich Schultheis, Prince Arthur, Sénateur Vaisse, Horace Vernet, Mrs. Caroline Swales, Countess of Rosebery, Xavier Olibo, and Earl of Pembroke. Front row: Duchess of Bedford, John Hopper, Prince Camille de Rohan, Duke of Wellington, Fisher Holmes, Marie Finger, Duke of Connaught, Innocente Pirola, Louis Van Houtte, Baroness Rothschild, Marie Verdier, and Marie Baumann.

A special prize, consisting of a Rose trophy, value 7 guineas, and the National Rose Society's silver medal, was also offered for a collection of six Roses to be grown within a radius of four miles of the Croydon Town Hall. This naturally excited considerable interest amongst local growers. Six stands were in competition, the winning one being that of Ernest Wilkins, Esq., Lyndhurst, Sutton, who had good examples of Etienne Levet, Comtesse d'Oxford, Charles Lefebvre, Ulrich Brunner, Madame Gabriel Luizet, and A. K. Williams.

In the plant classes Mr. G. King, gardener to Phillip Crowley, Esq., Waddon House, was a successful competitor, and he carried off several leading prizes with specimens of moderate size, but distinguished by their clean healthy condition. Miscellaneous exhibits also contributed to the attraction of the Show, but the weather proved very unfavourable during the greater portion of the afternoon.

EVENTS OF THE WEEK.—As will be seen from the list on another page, the Rose Shows are still numerous, but the principal event will probably be the National Rose Society's Exhibition at the Crystal Palace on Saturday next, and one of the members of the Committee writes respecting it, "Should the weather prove at all favourable it will be the best Show we have held, at all events for many years." The Royal Horticultural Society's Committees will also meet on Tuesday the 10th inst., in the Drill Hall, James Street, Victoria Street, Westminster, the Twickenham and Ipswich Shows being fixed for the same days.

— At the next meeting of the ROYAL HORTICULTURAL SOCIETY on July 10th special exhibits are expected of Roses, Lilies, and Strawberries, and Messrs. Laing & Sons, Forest Hill, offer prizes for Begonias to amateurs and gardeners—viz., for six singles, distinct varieties, 40s., 30s., and 20s.; and for three doubles, distinct varieties, 20s., 15s., and 10s.

— OUR Entomologist writes:—"I see a correspondent inquires about the EGGS OF THE EARWIG. It would be no doubt an excellent plan to keep the pest under by destroying these, but unfortunately they are seldom to be found. What we might call the earwig season extends from July to October, when the insects are only too manifest. During their breeding time earlier in the year we have few opportunities of observing them, as parents and young live more or less concealed from view."

— THE SHOW PELARGONIUM DUCHESS OF TECK as represented by a truss forwarded to us by Messrs. Fisher, Son & Sibray is a useful variety. Its characteristics are a bold truss, large handsome flowers; the petals substantial, crimped, and of snowy whiteness, and very large leaves. The stamens are bright reddish-purple, and present a distinct and pleasing contrast with the pure white of the petals surrounding them.

— We are informed that the annual Exhibition of the EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY takes place on Wednesday next, July 11th, in the grounds of the Royal India Asylum, Elm Grove, Ealing and the prizes will be distributed by the Duchess of Teck.

— To see OMPHALODES VERNA in perfection select a moist, shady position, where it will soon spread into large handsome patches and give abundance of its intense blue flowers annually in spring, sufficient to satisfy the most fastidious. In some parts of the country it carpets the ground, and in spring is a perfect picture. There is a white variety but it does not equal the type for general effectiveness.

— PAPAVER ORIENTALE.—"Amongst the numerous varieties of Poppies," writes "E.," "not one is more showy at the present time in the borders than is orientale, its brilliant scarlet blossoms with a large black blotch near the base of each petal renders it extremely showy. It grows freely and increases fast, no difficulty need be experienced in obtaining a stock of this handsome border plant."

— THE same correspondent remarks—"When growing singly on the grass QUINCES of good dimensions are very ornamental when in flower, as they have been this season, covered with their large white blossoms. Where spring-flowering trees are in favour many worse ones than ordinary Quinces could be planted."

— THE numerous species and varieties of OENOTHERAS form a pleasing group of plants with yellow flowers; for the most part, free and useful for borders. *O. scrotina*, *fruticosa*, *Youngi*, and *riparia* have yellow flowers in great profusion, and grow about 2 feet high. *O. macrocarpa* also is yellow, but of procumbent habit. *O. eximia* and *speciosa* have large handsome white and fragrant flowers; the latter sometimes fades to rose and flowers in the wildest profusion. It attains nearly 2 feet high, and may be regarded as one of our best hardy plants either for the rockery, the border, or for bedding purposes.

— **FRUIT EXHIBITION AT VIENNA.**—A Fruit Exhibition will be held by the Association of Austrian Pomologists, under the patronage of the Archduke Charles Louis, at Vienna, from the 29th of September until the 7th of October next. Two sections of this Exhibition are international—namely, that for fruit-drying apparatus and that for machinery and implements used in cultivating and harvesting fruits. Applications for space in the international sections should be directed before the 15th of July to the K.K. Oesterreichische, Pomologen Verein, Leschwald, Graz, Styria, Austria.

— "How seldom do we see *PERNETTYA MUCRONATA* in private gardens?" writes "S.," "yet it never fails to flower abundantly at this time of the year; it will grow in almost any position, and even under the partial shade of trees it does fairly well. This *Pernettya* is well adapted for planting in a much exposed position where south-westerly or east winds are troublesome. We have it on the south-west side of a bed of *Kalmias* and *Ghent Azaleas*, which are much exposed otherwise to wind from that quarter. When planted in peat it grows fast, throwing up strong vigorous shoots from the base, and is easily increased by dividing the roots. Its pure white flowers are very showy produced as they are in such profusion; afterwards the berries, which are borne freely, render it again attractive. Being low-growing and dense also, it is much more valuable than any other shrubs."

— AN interesting example of BUD-SPORTING IN PEACH TREES is brought to our notice by Mr. J. Willard, Holly Lodge Gardens, Highgate, who writes:—"The three Peaches sent are from the same tree (*Violette Hâtive*): The green one shows the stage of the crop; the other two are both from the same shoot, and have taken a lead throughout. The house has been treated for the growing crop as to moisture, &c. Under these conditions I should not expect much in the way of flavour. Their swelling and ripening so much earlier than the rest of the crop on the trees I thought remarkable, and shall be much obliged for an opinion in the Journal. The tree has shown a tendency to gum in places, beyond this I can see no causes." Two of the fruits are over-ripe, size 10½ inches in circumference, the other representing the crop quite hard and 6 inches in circumference. The ripe Peaches appear to differ from *Violette Hâtive*, and it seems desirable that endeavour should be made to "fix" the sport by budding.

— **THE GARDENERS' ORPHAN FUND.**—At the monthly meeting of the Executive Committee on Friday night last the gratifying announcement was made that a sum of £330 had been received from seventy-four local secretaries, and that nearly £70 had been received during the preceding week from other sources. The total amount now received is £1800, of which £1000 is invested in Consols. Mr. C. H. Sharman was elected an Auditor in the place of Mr. Fraser, who is unable to attend. Preparations were made for the election and first anniversary dinner on July 13th, and it was hoped that gardeners will, as far as possible, make it at the time for visiting London and joining in the gathering, which is expected to be representative and enjoyable. We hear many gardeners fancy those who have but one vote can vote only for one candidate, and we are desired to state that subscribers of 5s. can give one vote each to any six candidates, or if they especially wish to have a particular candidate elected they can give one vote to that candidate only. But it must not be imagined the votes are cumulative, as in School Board elections, and that six votes can be given to any one candidate for a 5s. subscription.

— A CORRESPONDENT writes:—"GRAPES ON WALLS have broken well, and bunches are plentiful. Well attended to there is a prospect of the crops ripening; if neglected, a failure must result. The shoots ought to be freely thinned, leaving one only to each spur, and in the case of young canes it is frequently advisable to thin the laterals, crowded growth preventing the ripening of both the crops and the young wood. Stop all fruiting or reserved shoots not required for furnishing blank space at either the first or second joint beyond the bunch, and before the bunches weigh them down tie in or otherwise fasten all to the walls or trellises. Where the old rods fail to bear fruit, lay in young canes either in short lengths or at the base. The former being trained along the old rods and stopped when about 18 inches long will become fairly stout and well ripened, and without any pruning will produce fruitful shoots next season, these to take the place of the old and useless spurs previously sawn off. If it is intended to wholly replace worn-out rods

with young ones, give the latter good room to develop, and stop when about 6 feet long. Leaders on young Vines also to be carefully fastened to the walls, and be duly stopped when they are 4 feet or more in length, or according to their vigour. Lateral growth from ripened wood to be kept stopped at the fourth or fifth joint, and from the young canes at the first joint."

THE OLDFIELD ORCHIDS.

THE first portion of the collection of Orchids formed by F. A. Philbrick, Esq., Q.C., at Oldfield, Bickley, was sold on June 26th and 27th at Messrs. Protheroe & Morris's Rooms, Cheapside, and as many rare and valuable plants were included, numbers of Orchid growers were attracted and some good prices were realised. Some of the most important plants sold were the following, with the prices attached:—*Cypripedium villosum aureum*, 10 guineas; *Cœlogyne cristata Lemoniana* (Veitch) 12 guineas and 21 guineas; *Lælia lilacina*, a natural hybrid between *L. Perrini* and *Cattleya crispa*, a plant with twelve pseudo-bulbs, 21 guineas; *Cypripedium Veitchi*, fine plant with eight flowers, £23 2s.; fine plant and good variety of *Cattleya Trianae*, 15 guineas; *Cattleya Trianae Backhouseana*, 13 guineas; *Cattleya Mossiae grandidissima*, 16 guineas; *Cattleya Trianae Clio* with fifteen pseudo-bulbs and two growths, large flower, £24 3s.; *Phalenopsis Stuartiana nobilis* (true), 12 guineas; *Cœlogyne cristata alba* with fifteen pseudo-bulbs and seventeen breaks, 18 guineas; *Lælia elegans Turneri* with fourteen pseudo-bulbs and two breaks, £27 6s.; *Cypripedium politum*, a fine plant of this hybrid with four breaks, 11 guineas; *Lælia anceps Dawsoni*, a strong plant, part of the original figured in the "Orchid Album," vol. i., £31 10s.; *Lælia anceps Schroederi*, a fine plant, 17 guineas; *Cattleya Mendeli Wallacei*, a grand plant with twelve pseudo-bulbs and two breaks, £23 2s.; *Cattleya Mendeli* hybrid with six pseudo-bulbs, 11 guineas; *Cattleya Skinneri alba* with eight pseudo-bulbs, 15 guineas; *Phalenopsis Schilleriana*, 10 guineas; *Cypripedium cardinale*, two leads and two growths, 12 guineas; *Cypripedium insigne Chantini*, a fine plant, 10 guineas.

VANDA BATEMANN.

THIS strong-growing and somewhat rare Vanda is not very frequently met with, only in gardens where Orchids are extensively cultivated, the reason probably being that it is not sufficiently free blooming to merit a place in smaller collections. There is a strong plant which is now producing its vigorous flower spike in the gardens of J. Deham, Esq., Sneyd Park, Bristol, the blooming of which is exciting some little attention, as it forms one among very few, if not the only specimen in the neighbourhood. It is growing in a pot some 14 inches in diameter, and if I remember rightly, it has fourteen pairs of its stiff, broad, pale green leaves on the principal growth. It has two other small leads, a third having been removed for the purpose of increasing the stock. The plant has been growing for some time at the shady end of a large span-roofed stove, a position that has evidently suited it well. The flower spike promises to be of a good length, and will continue the display over a long period, the buds being disposed at rather wide intervals along the stem, this being at the time of my visit about 2 feet in length. The first bud, although not nearly open, was just assuming its richly coloured tints, while the point suggests the possibility of many more flowers to follow for a long time hence. Mr. Rye, the gardener, has had this plant for several years under his charge, but this is the first flower-spike formed since its importation.—W. S.

THE DOWNSIDE ORCHIDS.

MANY regrets were expressed when it became known a few weeks ago that the estate of William Lee, Esq., Downside, Leatherhead, was to be shortly sold and the magnificent collection of Orchids dispersed, for numbers of Orchid lovers have had the satisfaction of inspecting the well-grown plants included in the extensive ranges of glass houses. The sale of the first portion of the collection is fixed for July 10th, 11th, 12th, and 13th, at Downside, and no doubt it will constitute one of the most interesting gatherings of the kind yet held. For the four days 1280 lots are enumerated, comprising many valuable hybrids, and rare, or in

some cases unique, plants. The collection is especially rich in *Cattleyas*. Those who have seen the large span-roofed house filled with specimens in flower will not readily forget the spectacle. *Cypripediums* also comprise scores of choice plants, *Dendrobiums* and all the larger genera being proportionately represented. The situation, houses, and treatment have evidently suited the plants exactly, for they are in vigorous health, a recommendation which Orchid purchasers readily appreciate. The sale will commence each day at 12.30 P.M.

ROYAL HORTICULTURAL SOCIETY.

JUNE 26TH.

SCIENTIFIC COMMITTEE.—R. McLachlan, Esq., F.R.S., in the chair Present: Messrs. Boulger, O'Brien, Church, Murray, D. Morris, Dr. Masters, and Mr. Ridley.

Mr. Ridley reported that the *Odontoglossum* referred to him for a name at the previous meeting was a form of *O. oblongatum*.

Aluminium in the Ashes of Plants.—Professor Church contributed a summary of his highly interesting and important researches upon the presence of aluminium in the ashes of plants. This substance, instead of being peculiar to the species of *Lycopodium*, as once supposed, is found in minute traces in the ashes of very many others, a circumstance not to be wondered at, considering the abundant distribution of the element in many soils. It occurs in all the species of *Lycopodium* examined, except those which are of epiphytic habit, and which, consequently, do not directly derive their food from the soil. It does not occur in the allied genus *Selaginella*. It occurs in the ashes of some Tree Ferns in large proportions, sometimes forming as much as 20 per cent. of the ash, as in *Alsophila australis*, *Cyathea medullaris*, while from others it is all but absent. In the British species of Ferns little or no alumina has been found.

Weevil Attacking Rhododendrons.—Mr. McLachlan exhibited specimens of a beetle destructive to *Rhododendrons* at Sunningdale, and which he identified as *Strophisomus limbatus*.

Beetle Injurious to Tobacco.—Mr. McLachlan showed specimens sent from Trinidad of beetles injurious to Tobacco and Egg Plants in that island, and which he found to be a species of *Epitrix*, allied to that which feeds on *Atropa belladonna* in this country.

The Plague of Caterpillars.—Mr. McLachlan called attention to the notion that cold winters are injurious to insects—a notion he stated to be erroneous; although, no doubt, severe alternations of cold, heat, drought, or moisture were prejudicial to insect life. During the present season it was noticed generally that great destruction of foliage occurred from caterpillars which destroyed the succulent portions of the leaf and tied the framework and fragments together by a web of fine threads comparable with spiders' webs. These caterpillars were different in different cases. In the Oak they were species of *Tortrix*; in the Apple the winter moth was destructive; while in other cases the larva of the Ermine moth was exceedingly hurtful to leaves.

Heteroicous Fungi.—Mr. Plowright contributed specimens illustrative of the following notes:—

Æcidium on Pea and on the Bean.—This was produced on both plants by infecting them with the same infecting material—viz., *Uromyces fabæ*. The *Æcidium* on the Pea differs in appearance from that on the Bean, the pseudoperidia in the former being few and scattered over pale yellowish spots, while on the Bean they are crowded in thickened white spots.

Puccinia extensicola.—This produces a very handsome *Æcidium* on *Aster tripolium*. Mr. Plowright found the *Puccinia* last year at Wells-next-the-Sea, Norfolk, and produced the *Æcidium* this year on the leaf now exhibited.

Gymnosporangium confusum (Plowright).—This species has hitherto been confounded with *G. fuscum*. It occurs on Savins, but does not produce *Æcidia* on the Pear as *G. fuscum* does, but on the Hawthorn, Quince, and Medlar, specimens of which were exhibited. Professor Sorauer of Proskau had sent leaves of Hawthorn on which he had produced the *æcidiospores* of *G. confusum* from teleutospores sent by Mr. Plowright about a month ago. The *æcidiospores* of *G. clavariæforme* were also sent for comparison. All the specimens sent were the products of cultivation. A special vote of thanks was proposed by Mr. Murray for this and other contributions of Mr. Plowright.

Spiral Torsion in Mint.—Dr. Hogg exhibited a specimen of Mint in which the stem was so twisted that all the leaves were placed in one continuous line. The phyllotaxis, as pointed out by Mr. Henslow, is really not interfered with in these cases. The occurrence is not uncommon. [See Masters' "Vegetable Teratology," German edition, 1886, page 367.]

Opuntia Shoots.—Mr. Morris exhibited joints of *Opuntia monacanthus* and *O. Dillenii*, which bore seeds in their interior, shoots from their upper edge, and roots from their lower end. [Analogous cases were observed as long ago as 1832, and various references to similar phenomena are given in Masters' "Vegetable Teratology," German edition, 1886, page 207.]

Various Exhibits.—From the Royal Botanic Garden, Edinburgh, came catkins and cones of *Pinus contorta* and other species of Coniferae. A malformed flower of *Odontoglossum crispum* from Mr. Douglas was referred to Mr. Ridley. *Brassia caudata* and *Acanthophippium striatum* were also shown.

CÆSALPINIA JAPONICA.

THE relatives of the Cæsalpinias form a very distinct division of the great family of Leguminous plants, and are mostly distinguished by the

ing botanically or useful to some extent in their native lands, but seldom seen here except in botanic gardens. *C. japonica*, however, possesses more important claims to attention, as it would no doubt be

FIG. 2.—CÆSALPINIA JAPONICA.

comparative regularity of the flowers and the partial or entire absence of the Papilionaceous or pea-flowered characters so strongly marked in many other genera. Few Cæsalpinias are cultivated for their decorative value, and the majority are either tropical trees or shrubs, interest-

found largely in many parts of southern England, and Messrs. J. Veitch and Sons have tried it satisfactorily in their Coombe Wood nursery. Specimens in flower shown at a recent meeting of the Royal Horticultural Society showed the characteristics of this plant to the best ad-

vantage, and a first-class certificate was at once granted for it. The leaves are pinnate with small even bright green pinnæ, and the bright yellow flowers, not unlike some of the *Cassias*, are borne in graceful erect racemes, the individual flowers being on long slender stalks. It is of good habit and free both in growth and flowering.

EARLY RHUBARB.

I CAN but regret that, having sent you a sample of Rhubarb, which during a series of years I have proved to possess certain new characteristics in that vegetable, you should remark that my "experience is inadequate for determining whether the kind, with such characteristics, is or is not new." Having for some years made the plant a study, all I can say is that had there been known a Rhubarb which—wholly unforced by oak leaves, pots, tubs, or other contrivances—begins to bear usually by St. Valentine's Day, if not earlier, I think I should have heard of it. I am sure you would not consider me capable of designedly misleading other persons. Must I then conclude that you would advise me to reflect whether I am not myself misled in supposing that plant to be mine which I myself for years have ventured to cultivate carefully—one whose characteristic qualities have been advertised in no nurseryman's list—simply because nurserymen grow no plant with such properties, and, like honest persons, have never professed to have such on sale? I do profess to have Rhubarb such as is described in my prospectus, and such possibly as some relative of mine (though I cannot be sure of it) raised from seed, which has certainly been grown in my family for forty years, and which as certainly I have specially cultivated from ten to fifteen years in my garden. I consider it my own by inheritance as well as by a long course of culture given it. And, therefore, as in a free country like England, a man may do what he will with his own, I, without prejudicing my neighbours' plants, have called my plant the "Yaxley Vicar's Rhubarb." And I hope I have not unpardonably offended the usages of horticulturists, whom I very highly esteem, by standing sponsor to my own Rhubarb.

Allow me to observe that it is not correct to say that I am "selling roots of the variety." No copy of my prospectus has at present been issued without the "prices" having first been cancelled by the words written over them "Advanced proof," a term well understood among journalists. In that paper I was careful to say that I referred to the St. Martin's Rhubarb only, because it is admitted by gardeners to be "amongst" the earlier kinds. I cannot help being fully aware that there is a difference between St. Martin's Rhubarb and mine, when I have grown the two kinds for comparison side by side and seen the difference yearly for ten years.

I accept your thanks for the half-dozen stalks with leaves I sent you; only, however, after a special request made in your columns. They are from the fag-end of the crop, and have been, and must indeed remain, the very last I pull this year. I cannot, therefore, accept your advice to send a sample at this time of the year to any committee, however well qualified, of any Society however distinguished. What grower of sound judgment would think of exhibiting a vegetable of the earliest spring now after Midsummer Day? Only one thing—the peculiar form of the growing plant—can be seen now (and not much later) better than at any other time of the year. There are about one dozen well-established stocks to be seen. As, therefore, I have no secrets to conceal, I repeat my offer that, by appointment, without giving any away, I shall be happy to show it to you, or to any person you please to commission to come and inspect it, describe it, sketch it, or photograph it.

From none of the statements made in my prospectus do I withdraw one letter; willingly undertaking to justify every word, if, please God, I live till next spring. I hope you will print what I have here written.—W. H. SEWELL.

[We readily print this letter. It is precisely because we felt our correspondent incapable of designedly misleading that we presumed he would regret doing so inadvertently, and we suggested a course that would prevent the possibility. The Vicar declines to submit a sample of his Rhubarb now that its character is developed and its "peculiar form seen" to "any committee, however well qualified, or any society, however distinguished," for ascertaining whether it is really distinct from existing varieties or not; and asks, "What grower of sound judgment would think of exhibiting a vegetable of the earliest spring now after midsummer?" We do not know any grower who would hesitate to do so in the case of Rhubarb, and samples similar to the variety in question have been exhibited this year, at the time when their "peculiar form could be seen;" and we are bound to observe that although the time is considered unseasonable for submitting the Rhubarb in question for examination by competent authority, we are still invited "to inspect it, describe it, sketch it, or photograph it." If it is the wrong time for showing it we do not clearly see that it is the right time for figuring it; but perhaps the Vicar can reconcile his declination on the one hand and his readiness on the other.

It is our duty to say, honest personal conviction on the part of an owner of something believed by him to be new, distinct, and superior from anything of the same nature in cultivation is not sufficient to entitle him to attach to it a new name and sell it as a new variety, unless his conviction is founded on a much more enlarged experience than is revealed in this case. The variety in question appears to have been tested with the St. Martin's alone, and because it differs from that, which we

know by comparison, and because it is earlier, which we admit, the owner of it thinks that in this "free country" he is free to give a forty-year-old Rhubarb a new name, and send it out as a new variety. The fancy prices in the prospectus we are told are cancelled. Whether the variety was raised from seed or not, we repeat that the comparison with one variety alone, and that a second early, is obviously inadequate for determining whether the old favourite is new and earlier than all other varieties in cultivation or not. If after a full comparison it is certified as differing from them all, then its sale under a new name, and at any obtainable price, will be justifiable; but if it should happen to be identical with an existing variety largely grown, there can be no such justification. The negative evidence cited about nurserymen's lists is of no avail. Evidence of distinctness must be positive, and founded on trial with earlier varieties than the St. Martin's for public satisfaction.

As a sample of the Rhubarb under notice cannot be sent for examination by a well qualified committee at the present time because the merits of the variety can only be determined in spring, may we make another suggestion—namely, that a root be sent in the autumn to the Royal Horticultural Society's experimental garden at Chiswick, on the understanding that roots of the same size and character from the collection there be taken up and planted with it? If this is done, and the new comer is found to be distinctly in advance of them in hardiness, earliness, and sweetness, proving all that is claimed for it in the prospectus, its fame will be spread all over the country, and the value of the stock enormously enhanced.]

ARTIFICIAL MANURES.

AFTER perusing Mr. Dunkin's recent contribution to the above subject I felt considerably disappointed on finding a decided tendency on his part to perform a rapid flank movement in regard to the scientific application of artificial food to plants as evinced by his sturdy opposition to the use of "properly proportioned combinations." Why he should be so anxious to creep back under the safe shadow of his experience is evident. I was at one stage of this controversy flattering myself that our respective views would eventually converge to the "true system," but he apparently intends to make a stand on the present position, and I will endeavour to briefly recapitulate a few of the various modes, practices, or systems that have been elicited during this debate.

In the first instance we have a simple application of a specific artificial manure, but its repeated application does not prove satisfactory, so recourse is had to what I termed the "haphazard system," that is, by some other kind of manure. This course being challenged, the second or "semi-artificial system" was advocated, this taking its name from the faulty artificial being supplemented by natural liquid and solid manures. Passing from this point and calling up the names of successful cultivators to endeavour to bolster up his cause, we arrive at the "fad system, or anything for a change system," and from this is evolved "the experiential system," that is, anything for a change provided results are satisfactory. But a spasmodic study of chemistry shows that a greater certainty of effect can be produced by a knowledge of the nature of the elements administered and induced a move to the aim of all true scientists—viz., "the true system." To this system I had at one time great hopes of converting my adversary, but he has apparently found some of the chemical compounds "altogether too mysterious."

Against this formidable array of "systems" consecutively championed by your correspondent, I have but one—viz., "the properly proportioned combination of the elements needed system," which I brought forward, in the first instance, against the initial article, and to which I also alluded in conclusion in a recent article, yet your correspondent has failed, he says, to find a single instance in which I have taken into consideration the various stages of growth that plants pass through, and the condition they are in at the time of application, and also that he considers I have shifted my ground considerably.

That the "experience" system is a tolerably safe resort to the unsentient cultivator there is no disputing, as it cannot be maintained that a system known to give good results, even though it is a blind and clumsy one, is altogether objectional. Not that I intend this to add to Mr. Dunkin's jubilant attitude when he says he is glad to notice that I am gradually abandoning the ideas of the "properly proportioned combination of elements needed system" as unnecessary and impracticable, as it is my intention to stick to this text until he can prove more clearly than heretofore that we shall never reach that stage where we can take for our motto "Scientia docet." After pointing out a few of the positions taken up by Mr. Dunkin at various times, I do not think he will place all the inconsistency to my credit.

As your correspondent again alludes to the use of lime, I would remind him that he has not yet cleared up the point in reference to its action on soils in regard to the idea of its causing moisture to be retained in land that it has been applied to with the object of renovating its fertility. Possibly it may have been an oversight in the same way that I failed to bring forward further arguments anent market plants. While agreeing with much advanced regarding the altered conditions under which they are placed being an important factor in their degeneracy, there are still other points that should not be overlooked in dealing with the subject. For instance, those plants retained by the market grower to grow on receive special treatment by not being called on to carry their crop of flowers so long as the others. *Erica hyemalis* and its companions would

be cut down long before its flowers commenced to fade, and Azaleas would be stripped of their buds even before they had time to expand. Again, taking a scientific view of the case, and presuming that they had been fed continually on nitrate of soda or some other equally strong ammoniacal stimulant, their vigorous growth would, according to scientific teachings, have absorbed the bulk of the phosphoric and potassic constituents from the limited portion of soil at command of the plant; hence the usual dose of nitrate or other similar substance would fail to have any effect, so that here we have an explanation of the circumstance, "that when one kind of manure is continued for several weeks the plants receiving it do not respond to its stimulating influences so readily as when it was first given. When such is the case give a few applications of clear water, and then supply some other kind of manure, and health and vigour will follow." It was to this vague and unscientific advice given in an article of his on "Artificial Manures for Pot Plants," that Mr. Dunkin will please to recollect that I took exception, though since then the debate has expanded, and other points have been raised that make it desirable to drop the latter part of the heading. The questions at issue are substantially the same, and may, I think, be summed up as follows:—Firstly, Is a change of food for plants necessary? Secondly, Is it possible to produce a perfect plant food? Thirdly, Will experience triumph over science? The first question, I think, my arguments are clearly against, provided the second can be answered in the affirmative, and the third I should answer by advising that the "p. p. e. system" be given a trial.—M. COOMBE, *Ashton Court, Bristol.*

RICHMOND.

RICHMOND is in many respects the most favoured of the larger towns surrounding the metropolis, which may be now almost described as part of the suburbs, so rapidly have the lines of houses extended. The valley of the Thames offers many attractions from Kew onwards, and the exceptional beauty of the view from Richmond Terrace is widely famed. From the Terrace Gardens also delightful prospects are obtained, and the townspeople may well value such an important acquisition. But it is the great park which more than anything else gives Richmond its pre-eminence, and were this its only attraction it would be a favourite resort for visitors, and one that should be preserved with the utmost care. A walk on a bright summer's morning from the gate near the "Star and Garter Hotel," across to the Robin Hood Gate near Wimbledon Common and thence to the Sheen Gate, gives an adequate idea of the charming wildness and sylvan beauty of Richmond Park, at present unmarred by anything of an incongruous character. In taking the route named and avoiding the roads, the Pen ponds are passed, and then on the rising ground to the left is seen the pleasantly situated residence of the Duke and Duchess of Teck, to which a few notes may be devoted.

WHITE LODGE GARDENS.

The pleasure grounds surrounding the mansion are of an unpretentious character, their chief attractions being the well-kept lawns, vigorous shrubberies of old tree-like Rhododendrons, shaded walks, and borders of homely flowers such as one delights to find in country gardens. Especial favourites are East Lothian Stocks, and some beds of a capital strain of these have been yielding abundance of massive spikes of large double bright red and pure white flowers. The seed is generally sown in the beginning of August, the seedlings being kept in pits or cold frames during the winter, and placed out in spring, when they soon make fine plants, and the following season are bushy specimens of considerable size and very useful. Irises, too, are favourites in the borders with Carnations, while Roses occupy a number of beds, miscellaneous hardy plants of the most reliable habit and showy character filling all other border space. Amongst the shrubs very conspicuous is the Mock Orange or Syringa (*Philadelphus coronarius*) and its varieties. These must have been planted freely some years ago, for the bushes are of great size, and during the closing weeks of June they filled the air with the powerful fragrance of their numberless flowers. Besides these, Lilac, with red and white Hawthorns, make up the greater part of the shrubberies with the Rhododendrons already mentioned. Several Conifers seem thoroughly at home, but the finest specimen amongst the trees is a wonderfully large spreading example of the Copper Beech, which covers with its branches a space something like 100 feet in diameter. Seen on a sunny day when approaching from the Pen Ponds, this Beech has a remarkably fine appearance in contrast with the various green tints of the trees in the background.

The kitchen garden is about a mile from White Lodge, near Sheen Gate, and there the gardener, Mr. J. S. Lindsay, gives good evidence of his practical knowledge and skill. The garden occupies a space of 3 or 4 acres, rather narrow, and of great length, running east and west, the only advantage of this form being that it gives a fine extent of wall space. The principal wall is on the north side, which is 525 yards long, the south aspect being occupied mainly with Peaches, Nectarines, Plums, Cherries, and Apricots, the majority well-developed healthy fruitful trees, but some trouble is experienced with the last named. Peaches constitute an important crop, and with the exception of two or three trees are bearing well, having in this respect much the advantage of those in many gardens, that were severely damaged when in flower this spring. The favourite varieties are the following—Hale's Early, chiefly relied upon for early supplies under glass; Early Rivers and Early Albert, which has fine-looking fruits with white flesh, but is liable to come with split stones; Early Silver, one

of the Sawbridgeworth seedlings, and Dr. Hogg from the same source, are both found to be good varieties; Bellegarde and Lady Palmerston coming in well for mid-season and later supplies. Only one tree of Royal George is grown, as it is found to be especially subject to mildew, and this season it is the only one so affected. The Nectarines are Lord Napier, Prince of Wales, and Pine Apple, the first being valued for its appearance, and the two latter for their flavour.

Of Apricots Hemskerk is the least liable to canker, and is hardier than Moorpark, though the latter is superior in quality, but Plums are so much more satisfactory that they are gradually superseding the Apricots. Varieties of the Gage type have been planted freely and look well. Particularly noticeable also is Rivers' Early Favourite, a fine oval purple Plum of good flavour, extremely prolific, and on a warm wall like the one under notice is evidently very early. Transparent Gage, Guthrie's Late Gage, and Pond's Seedling promise equally fine crops. Cherries are a favourite fruit at White Lodge, and large supplies are obtained from a number of healthy trees occupying the wall at the lower portion of the garden, and the crops this season look extremely satisfactory. An early variety in much request is the Early Purple Gean, which in favourable seasons is ripe at the beginning of June. Dr. Hogg says in the "Fruit Manual" that "this variety was received by the London Horticultural Society from M. Decandolle of Geneva in 1822; and by M. Decandolle it was procured from M. Baumann of Bolwyller." The fruit is large, becoming when fully ripe of a purplish black colour; the flesh is also dark, juicy, with a rich flavour, and excellent for dessert. The tree is of good habit and very free, but is said to require the Mahaleb stock to ensure its success. Another fine early variety is Empress Eugénie, which is one of the May Duke type, but considerably earlier, the fruits large and juicy. Black Eagle is also a reliable highly approved variety.

Cross walls at intervals have both east and west aspects filled with Pear and Morello Cherry trees, the former in many varieties, but all carefully selected for special qualities. One warm corner is occupied with a White Marseilles Fig, which ripens its fruit, and a large space in the lower garden is occupied with Filberts and Cobs, that serve for shelter. The kitchen garden quarters are closely cropped, and Peas are coming in freely. The early supplies are derived from three varieties—namely, Sangster's No. 1, Ringleader, and William I., which were all sown at the same time—viz., December 1st, and a good succession is thus secured. Sangster's No. 1 has been yielding good pods for over a fortnight, and the other two follow naturally in the order named. This practice is followed every season, but it is usual to sow a week earlier. Amongst Potatoes Mr. Lindsay commends Snowdrop as an early variety, being both prolific and of good quality; in frames the tubers come particularly fine, clean, and good. Several pits and frames are devoted to early Potatoes, Cucumbers, Melons, and Tomatoes, and that they are utilised to the best advantage may be judged when it is stated that one from which successive crops of Asparagus and Potatoes have been cleared is now occupied with Melons. A three-quarter span Peach house has some handsome trees on front and back trellises. Hale's Early, Early Albert, Dr. Hogg, Bellegarde, Stirling Castle, and Barrington being the varieties. There is also a small vinery and Cucumber pit, the former containing good Black Hamburgs colouring well, and the latter contains fine bunches of Muscat of Alexandria, grown on Vines in an extremely limited space both as regards their roots and stems. Mr. Lindsay is one of those quiet determined characters who does not readily give way to difficulties, but rather takes a pleasure in overcoming them, and this is amply shown in the Grapes as well as other products.

Two other objects require special mention—namely, the wall coping and *Tropeolum speciosum*. For several of the cross walls a copings formed of feather-edge boards is employed, which is readily secured by means of nuts and screws, and as readily removed. Early in the season this is convenient for suspending protective material when the trees are in flower, or preserving the fruit, but when these coverings are no longer required the copings are removed and the trees receive the full benefit of all the rain that falls. They are easily and cheaply constructed, durable, and thoroughly efficient. *Tropeolum speciosum* is usually found difficult to grow in the south, but in the White Lodge kitchen garden it is flourishing almost as well as it is seen in Scotland. It was planted six years ago in prepared soil, stiff clay being plentifully used, and it has remained ever since, the growth now trailing over a trellis and amongst the Gooseberry bushes more like a weed than a plant of delicate habit or difficult culture. When covered with brilliant flowers, as it is every season, it furnishes quite a blaze of colour.

From the Duke of Teck's garden to the Exhibition of the Richmond Horticultural Society, of which he is President, is perhaps an appropriate transition, and so a few informal notes upon what ranks as one of the best shows around London are here given.

THE RICHMOND SHOW.

The fourteenth Show of the Richmond Horticultural Society was held on Wednesday, the 4th inst., in the Old Deer Park, the display of plants, flowers, fruits, and vegetables being highly satisfactory throughout. The district is an important one horticulturally, and the local rivalry, not only between amateurs and gardeners in Richmond, but between those and the Twickenham exhibitors, has assisted materially in the development of the Show. In any case one of the strong points is the uniform merit of the exhibits in all the classes, and this is the best indication of the good work the Society is performing. With the

aid of a strong Committee, an able energetic Chairman, T. Skewes Cox, Esq. ; a well known Vice-Chairman, Mr. G. Nicholson ; and a courteous Secretary, Mr. J. H. Ford, with his attentive assistant, Mr. E. F. Gribble, the Richmond Society has amply maintained its reputation.

The weather was most unfavourable, frequent showers occurring during the day, but though this undoubtedly had a deterrent effect upon intending visitors, the exhibitors entered in their usual numbers, the competition being very keen in some classes. Three large marquees were filled with exhibits ; one was devoted to cut flowers, bouquets, and stands of flowers, another to specimen plants and groups, and a third to fruit, vegetables and cottagers' productions, the quality throughout being most commendable. It is impossible in the present issue to give a full list of the prizewinners and exhibitors, but a few of the principal may be noted. In the cut flower tent the Roses were well represented, Messrs. Turner, Paul & Son, and Rumsey being the most successful of the trade competitors, while in the amateurs' classes, R. E. West, Esq., and J. P. Kitchen, Esq., took the lead. Numerous tasteful stands and baskets of flowers were shown, Messrs. Barr & Son and Mr. T. S. Ware having extensive groups of hardy flowers not in competition. The second large tent comprised the specimen plants from Mr. Bates and Mr. Munro, the latter showing Ferns well ; Orchids from H. Little, Esq. ; Pelargoniums from Mr. Turner ; a capital group of plants, first in its class, from Mr. Wm. Brown, and collections of plants from Messrs. Veitch & Sons, B. S. Williams, C. Lee & Sons, and others, for some of which medals were awarded. The fruit and vegetable exhibits were excellent, Messrs. Osman, Bates, Feist, and Munro winning the chief prizes in the former classes, but several of these, together with the vegetables, merit a few farther notes next week.—L. CASTLE.

A PLAGUE OF CATERPILLARS.

DURING the last three weeks we have been visited here by these pests, which have attacked the young growths of the Oak, Ash, and Hazel in the woods. About a third of the trees are completely stripped of every green leaf, making them seem when looking at them from a distance as if they had not yet burst into leaf. Sweet Chestnut and Birch trees are not apparently touched.

In the garden they have attacked and entirely stripped the Apple trees, also Pears, but Cherries and Plums have escaped with only a few leaves eaten. Gooseberries and Currants entirely escaped. A few days after they first appeared numbers of rooks were busily searching through the woods for them, and nearer, and in the gardens, the starlings and house sparrows were busy going from tree to tree in search of them. Never having seen so much damage done by them before, I should be glad to hear from correspondents if they have appeared in other places, and what damage they have done. Here they have been very local, as in gardens a few miles distant scarcely any have been noticed.—T. GRANT, *The Gardens, Ossemsley Manor, Christchurch.*

HARDY FRUIT GARDEN.

EARLY STRAWBERRIES.—In order to secure a long succession of fruit it is advisable to plant in different positions, some being grown in the warmest part of the garden, still more in a fairly early open position, and others in cooler situations. Where there are good borders to the south and south-western walls a portion of these might well be annually given up to Strawberries. If a good breadth of ground cannot be spared the next best plan is to form a row of plants at the front parallel to and about 15 inches clear of the path. Quite young plants are always the earliest, and produce much the finest fruits. For these reasons plants on sunny borders ought to be cleared off every season as soon as the crops of fruit and runners are taken. These strong early plants also produce a number of strong early runners, or enough for both border and pot culture, and altogether are very profitable. If the ground just cleared of early Potatoes was well manured for that crop all that is necessary is to clear off all rubbish, level and trample the surface prior to following with early Strawberries. Very rich loose ground encourages too much leaf growth, but a little manure should be added to poor ground.

SUITABLE VARIETIES AND CULTURAL NOTES.—The good old Keens' Seedling is still one of the best for warm borders, and certainly preferable to Vicomtesse Hericart de Thury, this usually growing too vigorously, and producing too many small fruits. A trial may also be given to Laxton's King of the Earlies and Noble, both being very distinct, and on some soils very superior. Sir J. Paxton, though a little later than those just named, is yet one of the most profitable early varieties that can be grown, and ought always to be largely planted. This season, owing to the long spell of showery weather, it will be possible, in many districts at any rate, to lift plenty of well-rooted runners, these being already well established in the mulch and soil between the rows. Plants thus lifted with a good ball of soil and roots and replanted take most quickly to their fresh quarters ; but if they cannot

be obtained in this way the runners ought to be layered in small pots as soon as the crops are gathered and kept supplied with water. When well rooted they may be detached from the old plants and at once planted out. In planting see that the soil is not dry, and all ought to have the soil firmly rammed about the roots. The rows of Sir J. Paxton, Vicomtesse Hericart de Thury, and Noble ought to be not less than 2 feet apart, a similar distance separating the plants in the row. Less vigorous growers may be put out rather more thickly in the rows. All should be mulched with strawy manure, and if need be watered occasionally, and from such treatment profitable plants will result.

RASPBERRIES.—There is every prospect of a good crop of fruit being obtained from these, the rains have fallen opportunely. All fruiting canes should be kept well secured to the stakes or wires, and where the young suckers are at all crowded thin them out freely, this naturally favouring those reserved for fruiting next season, as well as admitting more light and air to the crops now maturing. If not already done heavily mulch the ground with strawy manure, and birds must be kept away with the aid of fish-nets fixed well above the rows of plants. Where suckers are formed in the open spaces between the rows these may be lifted with a small ball of soil about the roots and planted on good ground.

FRUIT FORCING.

PINES.—*Suckers from Early-fruited Plants.*—Plants started early in the year for fruiting will now in the case of early sorts have ripened their fruits, and the later varieties will be so advanced as to admit of their being removed to ainery or other house rather cool and dry, which will prolong the season and admit of the successional plants being afforded more room and light to induce a sturdy habit. Let there be no delay in obtaining the suckers from the early rooted plants, potting them in fibrous loam rammed firmly into the pots and around the base of the suckers, watering at once, having in readiness a bed of fermenting materials at a temperature of about 90° at the base of the pots to plunge them in. They root best in a close moist pit. In plunging bring the material over the surface of the pots so as to prevent the soil becoming dry near the top, the soil will then have sufficient moisture until the suckers have rooted, they doing so more quickly if shaded from bright sun and ventilated a little at 85°. Care must be taken not to subject the suckers to strong bottom heat. Beds that had a supply of fresh material in spring will not require any now. They may, however, with advantage be turned to a depth of 20 to 24 inches, but those that had not a renewal of the material in spring should have an addition of about a foot of new tan mixed with the old to a depth of 18 inches, avoiding if possible the making of new beds, but if it be necessary 24 inches in depth of new tan will afford all the heat necessary for the suckers.

MELONS.—*Late Plants.*—It is important that the late plants be placed out at once, especially where the means of affording artificial heat is confined to fermenting materials. Whether grown in pits or frames a sufficiency of fermenting materials should be used to raise a bottom heat of about 90° to start the plants quickly.

In Houses.—When the crops are cleared, the plants, if exhausted, should be removed, and preparations made for a fresh start at the earliest opportunity, but if the plants are in good health it is sheer folly to root them out, as they will come into bearing again much sooner than young plants, and are in every way more tractable ; indeed, if the plants are not overcropped, do not suffer from insufficient water at the roots, and the foliage is kept healthful, they will continue bearing as late as is desired. When the crop is cut the plants should be divested of most of the old or damaged leaves, fresh growths being encouraged in the place of any exhausted, which should be cut away. Loosen the surface of the bed, removing some of the soil, and apply a couple of inches of fresh loam, giving a good watering. When growth is taking place afford an application of liquid manure, and then treat as for former crops. When Melons are grown upon the continuous system it is well to note that the laterals will grow somewhat freely and show fruit abundantly after a few joints of growth. The flowers after being impregnated will set and the fruit swell freely, so that sufficient moisture only need be accorded to maintain the plants in continuous bearing. Attend to stopping, thinning, tying, or otherwise regulating the growths, not allowing pressure of work in other departments to interfere with this, or the results will be so detrimental as to be difficult to remedy.

PEACHES AND NECTARINES.—*Early Houses.*—The very early houses will be cleared of fruits, and should be treated as advised in our last calendar under this head. Those, however, who do not commence forcing until the new year, and have nothing earlier than Hale's Early, Royal George, Grosse Mignonne in Peaches, and Elruge in Nectarines, will not this year have been able to gather ripe fruits before the second or third week in June, unless the trees have been subjected to more artificial heat than considering the adverse season is good for them. If very early fruit is wanted, varieties that afford it under circumstances that are fatal to its production by others subject to the same treatment should be chosen. For very early fruiting Alexander and Waterloo are valuable. They are of good size, and have plenty of colour. They are clingstones, yet have good flavour, but it is no use expecting to find in the very early Peaches the same quality as obtains in such kinds as Hale's Early, Early Alfred, Early York, Dr. Hogg, &c., which are first-rate in every respect, and are succeeded by the standard sorts, such as Royal George (Stirling Castle is a very fine form of this best of all Peaches for forcing taken all round), Grosse Mignonne, Bellegarde, Noblesse, and Barrington, which are unsurpassed by any. Of the very

early Nectarines there is Advance, but it is well worth waiting another fortnight or three weeks for Lord Napier, which is a capital sort, indeed it is best of the early Nectarines, and leads up to Elruge, Violette Hâtive, Pine Apple, and Victoria. These are mentioned not in disparagement of others, but as thoroughly reliable and unsurpassed in quality. When such are grown they must not be forced to ripen with the very early varieties, or the fruit will not finish satisfactorily; in fact, to have good fruit—the finest—the trees require time to accomplish good work. Trees started early in January will not, to do them justice, ripen their fruit before early June. This year the fruit is ripening a fortnight to three weeks later than usual, Hale's Early not being ripe before the close of June, and Royal George until early July. Now, the point is this, Forced against weather the fruit would have ripened three weeks earlier at a great sacrifice of size and quality of fruit. These are matters worth the attention of those expecting produce of the finest quality. When the fruit commences ripening water should be withheld from the foliage and fruit, a gentle warmth being maintained in the pipes to ensure a circulation of air constantly, and to prevent the deposition of moisture on the fruit through the night. Air should be freely admitted, and if the weather be very hot and the panes of glass large, a double thickness of herring nets, or a single thickness of pillowcase nets, drawn over the roof lights will break the rays of the sun, prevent the undue heating of the fruit, and insure its gradual ripening, instead of being dead ripe at the apex whilst the lower part is quite hard. The tender skinned varieties, such as Noblesse, are liable when exposed to powerful sun, especially after a dull period, to have the fruit browned at the apex, and in some instances cracked, which spoils otherwise noble fruits. A little air moisture, secured by sprinkling available surfaces occasionally, will be of great service to the foliage, and will not do any harm provided the atmosphere is not close.

STRAWBERRIES IN POTS.—We are still gathering from plants under glass fine fruits of over an ounce weight of Sir Joseph Paxton, President, Dr. Hogg, and Sir Chas. Napier, and shall continue for another fortnight or three weeks. The outside ones are in, but they being of the early sorts make a poor display at table as compared with those above, and what is worse the quality of the outdoor earlies is very indifferent as compared with the late forced sorts. As soon as runners can be had they should be layered in small pots. We use 3-inch, into which lumpy rather strong loam has been rammed, adding a quart of bonemeal and a similar quantity of soot to every bushel of loam. The loam being turfy, manure is not added, but when otherwise we use a fifth of fresh horse droppings. A row of pots is half plunged between every two rows of plants in the open, which leaves a space between alternate rows for operating in layering, watering, &c. Strong runners are laid in the pots, one in the centre of each, a slight indent being made, and each secured with a peg made of galvanised wire, No. 12, cut in lengths of 2½ inches and doubled. With proper attention to watering the runners root quickly, and when the roots show at the bottom of the pots, and before they are rooted through into the soil, they are detached, stood under a north wall for a few days, and then potted. Runners are only taken from young vigorous plants, and such as have shown fruits; indeed, the best plants to get runners from are those that were planted last year as strong runners, being reservations of the forcing ones for the particular purpose. We still recommend the varieties La Grosse Sucrée and Vicomtesse Hericart de Thury for early, Sir Joseph Paxton and President for general work, and Sir Charles Napier and Dr. Hogg for late. Besides, we still have some Keens' or Sir Harry, James Veitch, &c., and Noble.

PLANT HOUSES.

Bougardias.—Plants raised from cuttings of young wood or portions of root should now be bushy and sturdy, ready for planting out or placing in their largest pots. If the first is practised, select a sunny spot where the base is firm or can be made so. The compost in which they are to be planted should be 5 or 6 inches deep, and may consist of ordinary garden soil, to which has been added one-seventh of decayed manure and a liberal portion of leaf soil. If the flowers only are needed in a cut state, the plants may be allowed to grow without pinching, strong shoots will issue from the base, and surprisingly large plants will be produced by September. When required for this purpose alone, they can be lifted with good roots and placed without repotting them on the bed of the house in which they are to flower. When required for decoration in pots planting out is not advised. Place them into 5 and 6-inch pots according to their size, and strong shoots that issue from the base must be pinched if an even head of bloom is desired. Carefully harden the plants before placing them outside.

Grevillea robusta.—Plants raised early from seed may be placed into 5-inch pots in a mixture of loam, sand, and one-seventh of manure. Press the soil firmly into the pots, and grow the plants as cool as possible so that they will be dwarf and sturdy. Plants grown to a decorative size under cool conditions in the latter stages last double the length of time that would be the case if drawn up quickly but weakly in heat. Smaller plants in pans or 2-inch pots may be transferred into 4-inch pots. Seed may still be sown, and small but useful plants can be produced by winter, or will be found invaluable during the spring months.

Dracena rutilans.—Plants that have attained too large a size may be reduced by taking off good well furnished heads. These should be cut off where the wood is moderately soft. Place the heads in 4-inch pots with a little sand in the centre for the base of the stem to rest upon. If plunged in the propagating frame, and shaded from the sun,

or even in a close moist structure, they will quickly form roots and be ready for decoration again in a short time. Young stock raised in heat early in the season will be ready for 5-inch pots. If the plants are not needed for some months grow them from the present time under cool conditions; by such treatment they make the sturdiest and most handsome plants. Under cool treatment they take fully double the time they need when pushed forward in heat. Young plants raised now by placing the root portion of the stem in heat will make capital plants for placing early in the year in 5 and 6-inch pots. These, after they are once established in small pots, may be grown and wintered cool provided they are not needed before the spring.

Adiantum cuneatum.—For yielding a good supply of fronds during the winter those plants that have been heavily picked up to the present time should be thoroughly cleaned by the removal of all small fronds. Give them a few weeks' rest in a moderately cool place and then push them into growth. Be careful not to grow the plants under too much shade, for fronds produced under such conditions will not stand after they are cut. A fair amount of light is essential, with air admitted liberally when the fronds are developing. This treatment will produce light green fronds that are more suitable for association with choice flowers than those of a dark green appearance. Plants that have their pots full of roots may be fed with weak stimulants to assist them in pushing up strong fronds. Pot seedlings, as well as any young plants that need more room at their roots. Plants well established in 60's will, if placed into 5-inch pots, yield a quantity of small but useful fronds during the winter. In potting, use a light open compost, loam and leaf mould in equal proportions, with sand and a little lime rubbish added. Leaf mould is preferable to peat.

THE BEE-KEEPER.

HOPES FOR THE HARVEST.

THE almost entire destruction of the Alsike Clover has jeopardised the bee-keeper's harvest. The cold winter and protracted severity of the spring, preceded by a drought of exceptional severity, killed the root with a result which can only be approximately estimated. Walking over some 700 acres of seeds a few days ago we noticed scarcely a single head of the sweetly delicate flower upon which the bee-keeper depends so much for his annual profit. If, however, the weather is propitious during the next ten days a considerable surplus may yet be obtained from the Dutch or White Clover of the pastures, which seems to flourish in unusual abundance, notwithstanding the exceptional heat of the past few days.

In some districts fruit blossom has yielded an average quantity of honey, but on the whole the result of the season has, so far, been a decided disappointment. Swarms also are few and far between, and many bees have lost their lives in the heavy storms of the past few weeks. But—and so much depends upon this—given a fine July, and there is every hope of an average harvest, provided that the instructions repeatedly given in these columns have been followed out, and all stocks are consequently now strong and ready to work in supers. Those stocks which have already worked out the frames of foundation given to them will increase in weight very quickly, unless the torrid heat of to-day, the 28th of June, continues and dries up the pastures, thus destroying our only hope, unless we have access to the moors, where the purple Heather will in August give another chance of retrieving past disaster. Now that the prevention-of-swarms system seems to have been very generally adopted there is always a greater certainty of obtaining a surplus, because every stock is always strong and ready to work in supers at the earliest opportunity, and consequently precious days are not thrown away in building up swarms which ought either to have been prevented from issuing, or at least built up either by strengthening or other means, ready for the time when the great annual harvest is expected to be gathered.

At the present time we must impress upon bee-keepers that their hope of a harvest depends upon their ability to restrain the swarming impulse. If all the bees of a stock are kept together instead of being divided between the swarm and the stock there is more than a hope for a tolerably successful season, but if a division is now made or allowed to take place there is hardly any possibility

of either swarm or stock being in a position to take advantage of the Clover harvest, although both may be prepared to work in August on the Heather. Unity is strength. Unity is profit. Day by day a strong stock or built-up swarm collects and stores a great weight of honey, provided the weather is favourable, but a weak stock or newly hived swarm must perforce look after present wants and leave the future to chance.

A few days ago we saw a bee-keeper who was in great distress because his bees would not swarm. He had supered them, and they were working in the supers, but he was under the impression that "prosperous bees always swarmed." He had read and learned a little knowledge. His little knowledge was somewhat dangerous; but he is happy now on receiving an assurance that he was on the highway to success and might hope to obtain better results from his undivided stocks than he had ever before obtained from his prosperous bees which always swarmed. At the present time the heat of a hive to which proper attention is not paid must be appalling, and we entreat every bee-keeper to see that proper precautions are taken to keep the blazing sun from baking the hives and melting down the new built combs, and thus destroying the stocks. This point must be at once attended to. Before we again put pen to paper our hopes will have been realised or blasted. If we have a good harvest may it be the precursor of many other equally favourable seasons; but if the weather fails us, and the harvest so eagerly expected from the Clover is not stored, then may we express the hope that another year a better season may be in store to keep awake our enthusiasm and to fan into a blaze the lukewarm interest of those who are ever ready to decry an industry if success is not a constant and faithful attendant on anything which they may deign to take up either for amusement or profit. In the course of a week or two instructions for the care of stocks after the season has ended shall be given, and we have no doubt that those who have their own interests really at heart will be the first to see that at the close of one season due and proper preparation is made for the following year.—FELIX.

[Since the above was written we hope rain has revived the pastures referred to. Sufficient has fallen near London for the present, and for some days the weather has been the reverse of favourable for bees.]

TRADE CATALOGUES RECEIVED.

Michael Rains & Co., 34, Mansell Street, City, London.—*Wholesale Catalogue of Dutch Flower Roots and Bulbs.*

Messrs. Deane & Co., 46A, King William Street, London Bridge.—*Illustrated Catalogue of Glass Structures, Summer Houses, Heating Appliances, &c.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Gardeners' Orphan Fund (*A. Wilson*).—Mr. Barron will be communicated with on the subject of your letter.

Synonymes (*G. T.*).—"Syn" is an abbreviation of synonym, which, used in connection with plants, means that all those grouped under it are the same—the same variety with different names.

Grapes not Setting (*J. M.*).—It is the result of imperfect fertilisation, the consequence either of a deficiency of pollen, or its insufficient dispersion through a too damp and close atmosphere. Cut out the small and leave the larger berries when thinning.

Seedling *Pancratium* (*G. H.*).—As nearly as we can judge from one rather damaged flower, your plant is nearly related to, if not identical with, *Pancratium caribæum*.

Tuberous *Begonias* (*W. M. McRobbie*).—The flowers sent are very fine indeed, and the foliage accompanying them shows conclusively that the plants have been excellently grown. They are a credit to you, and you might do service to others by describing your method of culture in the Journal.

Roses for Buttonholes (*A Young Subscriber*).—You could not do better than grow Rubens, President, Madame Falcot, Grace Darling, and Perle de Lyon; if you want a red one you will find W. F. Bennett, Hybrid Tea, useful. For flowering early Safrano and Isabella Sprunt will produce more buds than most others. The buds are thin and rather small, which with some may be an objection. In our Rose column will shortly appear under "Roses in Winter" a paper on the management of Tea varieties in pots, and in it, we think, you will find all the information you may require.

Roots on Vine Stems (*T. T.*).—These are incited by a close moist atmosphere, and when they are present under contrary conditions they indicate that the roots in the border are not supplying the wants of the Vines. Mr. Barron, in his book, says, "If the true roots are in a perfectly congenial condition, no air or adventitious roots will be produced in any ordinarily well managed vinery." They will probably do no harm to the Vine, and we should not remove them, but let them wither naturally. Are you sure the Vine is not being cropped too heavily? If it does not push sub-laterals freely that is the case.

Insects on Strawberries (*S. A.*).—Your plants are suffering from an attack of one of the snake centipedes (*Geophilus longicornis*). The specimens sent are about half the adult size. These insects have been remarkably troublesome in many gardens during the last three or four years. When it is discovered that Strawberries and similar plants are infested by them it is a good plan to dress in spring with quicklime, soot, and wood ashes mixed in equal proportions, applying this evenly over the whole of the soil, or gas lime may be worked in at the rate of half a peck per rod, combined with an equal quantity of dry earth. Quantities may be killed by baiting them with slices of Potato or Apple wrapped in a little hay and placed in the ground.

Caterpillars on Rose (*J. C. M.*).—The specimens sent are those of the small emerald moth, *Iodis lactearia*. It is not usual to find this species on Roses, the chief food being Whitethorn or Blackthorn in hedgerows, but it is liable to occur on other plants of that tribe, yet seldom numerous enough on any to do serious harm. There appear to be usually two annual broods. An emergence of moths takes place in May, these being parents of the June caterpillars, and, being of a delicate green tint, they are often unobserved amongst the fresh foliage. Hence they escape capture, as do also the caterpillars, from their mimicry of inanimate objects, by stretching themselves out rigidly, as do others of the Looper group. But it is likely insect-eating birds detect them by their pink markings on the light-green general colour of the body.

Temperature for Tomatoes (*Subscriber*).—The plants grow freely, and their fruit ripens well in a night temperature ranging from a few degrees below to a few above 60°, with a free circulation of air. No injury is done if the temperature falls to 55°, or even a few degrees lower now and then, but the ripening is retarded. The day temperature may be about 65° by fire heat alone, rising to 85° or even 90° with sun and a free circulation of air. A close damp atmosphere must be avoided, and while the house should not be quite closed at night more air must be admitted very early in the morning. So long as ventilation is managed judiciously, and the plants are otherwise properly attended to, a few degrees more or less by night or day are of no practical consequence, and the plants cannot have too much sun.

Pear Failing (*Ebor*).—We advise your examining the roots in autumn as you suggest; but from the abundance of bloom and the fruit not standing, we have doubts if the roots of the tree have enough moisture. Such appearances are often produced from extreme dryness and extreme moisture, but the latter can hardly be the case with such a bed of sand beneath. All you can do is to keep the roots near the surface so as to encourage the making of short-jointed wood, and mulch or cover the ground with tiles to keep it moist as well as warm. Are you sure that enough moisture is given? Such cracking is produced by various causes, such as a high dry temperature and a deficiency of moisture at the roots, and then again by plenty of moisture at the roots, considerable warmth, and a dry cold atmosphere. In the one case the fruit swells too fast for the root-action, and in the other it does not swell fast enough.

Tomatoes and Strawberries (*F. W.*).—No doubt muriate of potash is good for Tomatoes, but we have this to say, that if a person cannot grow them well without it, its absence is not a sufficient reason for the failure. Some of the finest crops that have ever been produced have been grown without muriate of potash. No one kind of manure can be named as absolutely the best for all soils, and all the fertilisers advertised are found serviceable by cultivators, some finding one the best and some another, according to the nature of the soil to which they are applied. As you evidently do not require a large quantity, you cannot do better than procure a small tin of each, and you will then be able to find which suits your soil the best. Finely ground bone meal and superphosphate of lime are good for Tomatoes in most soils. By the time this appears in print you will find whether the Strawberries will

swell or not after injury by the hail storm. You did right in applying light dressings of nitrate of soda for inducing a quick growth of new leaves, but had better not continue its use much longer.

Pink and Blue Hydrangeas (*T. C.*).—You ask if liquid manure of any kind given to Hydrangeas will cause the flowers to have a deep pink tinge, and add that, "alum will cause it, but it injures the plants." As alum is given to cause the flowers to become blue, and as they are usually more or less pink, perhaps you inadvertently used the word pink instead of blue. The plants are injured by alum when it is used in excess. On the subject of blue Hydrangeas a correspondent, who has had them in abundance, wrote some time ago:—"Iron rust is an excellent agent for changing the pink flowers of the Hydrangea to a deep blue. In a valley here there is a vast ochreous deposit arising from the action of the air upon mineral springs. Some thousands of cart-loads of the soil through which this water has percolated for a long course of years has been used for fruit stations and flower borders. All the Hydrangeas (about fifty in number) that have been planted in it have grown freely, and are annually laden with a profusion of flowers of a deep rich blue colour. This fact is as important as it is interesting, affording a hint of such value as to place blue-flowered Hydrangeas within the means of everyone. Here is my explanation. Ochre in its pure state is simply a combination of iron rust and water, technically termed a hydrated peroxide of iron or ferrie acid. If, therefore, common ochre be mixed with the soil in which Hydrangeas are planted the flowers will come blue, and the depth of colour will be pretty much in proportion to the quantity of ochre used as well as its condition. It is well to remember this, because the ochre of commerce is often much adulterated with substances which are only to be detected by a chemical test." Sulphate of ammonia at the strength of from a quarter to half an ounce to a gallon of water given to the roots twice or thrice a week deepens the colour of Hydrangeas.

House for Forcing Rhubarb (*Young Gardener*).—A lean-to facing east would answer very well. As you only require it for affording a daily supply, we presume for a private establishment, a house 6 feet 6 inches wide inside would answer, and the height at the back need not be more than 7 feet 6 inches. This will allow of a bed in front 4 feet wide, but $4\frac{1}{2}$ inches of the width would be required for a wall, which should be taken up 18 inches above the ground level, and have a wooden coping $4\frac{1}{2}$ inches by 2 $\frac{1}{2}$ inches. The front wall need not be more than 4 feet 6 inches high above the ground level. A flow and return 3-inch pipe will be sufficient; indeed you will require valves to regulate the heat where the pipes enter the house, and the flow may be fixed along the front a few inches above the surface of the bed, and the return in the pathway, either next the bed or against the wall. If the ground allow of the pathway being sunk to the depth of the bed, it would be an advantage as regards the height of the front wall. The best soil we have used for packing around the stools of Rhubarb for forcing is leaf mould. A temperature of 55° is necessary to have the finest stalks, but in forcing against time the temperature may be 65°. About a dozen stools of three-year-old plants must be introduced at intervals of a fortnight or three weeks, according to the demand, to maintain a daily supply, from three weeks to a month being needed from the introduction of the plants to gathering. As two or three rows of stools can be put in the bed the house would need to be about 18 feet long. It is usual to have a wider house in which to force Mushrooms and Seakale, as well as Rhubarb; and, whilst you are about it, it may not be undesirable to give the subject consideration, a larger structure being relatively cheaper, as it certainly is more useful than the smaller. We maintain a daily supply of Mushrooms, Seakale, and Rhubarb in the forcing season from a house 13 feet long and 11 feet wide, having beds on the floor on both sides 18 inches deep by 3 feet 6 inches wide, including the walls, for Rhubarb and Seakale forcing, and two beds on each side above them for Mushrooms, there being 18 inches space between the beds. The house is a lean-to with a north aspect. If you were to give a more precise account of your requirements we might be able to furnish a more definite reply.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*Unknown*).—The plant is *Pitcairnia punicea*, also known as *Pepinia punicea*, and is occasionally grown in gardens as *P. Jacksoni*. It is very handsome when grown like the specimen sent. (*Batila*).—A dark variety of *Cypripedium barbatum*. (*S.*)—The *Lilium* is *L. testaceum*; the *Odontoglossum* is a small variety of the *O. luteo-purpureum* type. (*M. C.*)—*Cattleya Reineckiana*, undoubtedly. (*G.*)—Probably *Rodriguezia crispa*.

COVENT GARDEN MARKET.—JULY 4TH.

BUSINESS remains the same with large supplies to hand. Prices generally easier. Outdoor Strawberries in full supply.

MANURES FOR PASTURES.

THE DYSON'S WOOD EXPERIMENTS.

THE end and aim of these experiments is to ascertain which manure, or mixture of manures, answers best for the promotion of a full development of all the Clovers and Grasses sown upon new pastures or found established in old ones, and not to induce rampant growth of a few at the expense of the remainder. That such important knowledge is surely, if slowly, being evolved, was clearly evident when our inspection was made on June 21st—slowly, because results are materially affected by weather, and this being so, experience has shown that greater certainty attends the result of hay crops than those of the aftermath, which is so frequently spoilt by the drought of summer. Repeatedly have we told our readers, as an unmistakeable result of our own experience, that the application of chemical manures not later than the end of February tends to promote such strong free growth as insures a full crop of hay. Sown then, the nitrogenous manure is quite certain to be dissolved and all of the manure washed down to the roots, and it is found that the growth of pasture so nourished is so little affected by cold spring weather that it is always comparatively

forward and robust. Imperfect, or rather unsatisfactory results have, in some instances, followed the application of manures in April at Dyson's Wood, and we hope Mr. Martin J. Sutton may be induced to try the effects of an earlier application.

Whether nitrogen is applied in the form of nitrate of soda or sulphate of ammonia, we would use it early, in combination with well-balanced proportions of muriate of potash, steamed bone flour, and mineral superphosphate. Experience has shown that nitrogenous and mineral manures should be well mixed, and the mixture be used by the end of February. There need be no fear of a loss of nitrogen, for the roots of a well-knit pasture permeate the soil so closely as to prevent this, and above all things we require an early robust growth if we would have a full crop of hay.

Upon the old pasture at Dyson's Wood the plot dressed last year with farmyard manure at the rate of 10 tons per acre has decidedly the best crop this year, and the advocates of muck were jubilant at this triumph, as we think we heard it termed. But was it not a hollow victory of muck over chemical manures? This matter after all resolves itself into a question of profit and loss, and we proved for our own guidance long ago that the advantage is very much on the side of the chemical manures. The cost of a ton of muck is very seldom ascertained with any approach to accuracy. Here the price given is 6s. per ton, but we question if that amount shows its real cost. In the last number of the Journal of the Royal Agricultural Society of England we have a series of elaborate calculations of the cost of fattening bullocks, and the cost of the manure per ton at Sir J. B. Lawes' experiments at Woburn, which go to prove that the average cost of manure obtained in this way actually amounts to £1 9s. 8d. per ton! "Dung," the writer very justly observes, "is merely what is added to the straw. If one waters one ton of straw, and does nothing else but let it lie about for a time, something like 4 tons of mere wet straw-dung may be obtained. The manurial value of a ton of straw is estimated at about 10s., therefore four tons of merely wetted straw is only worth 2s. 6d. a ton as dung. On the other hand, if a ton of straw be used as litter for twenty weeks for a fattening bullock receiving about 17 lbs. per day of cake, besides Clover, hay, and roots, the original ton of straw has most costly additions made to it." No doubt the muck used at Dyson's Wood had been manufactured as carefully as possible, but the ordinary process of making it in open yards and heaps is most extravagant, for by the time the muck is applied to the land its most essential properties have vanished in the air in the form of gas set free by fermentation. It is all very well to talk of the kindly influence of humus; the sentiment sounds—well, like a drum, for depend upon it there is very little in it. We had to take a large quantity of muck in valuation at a farm which fell in last Michaelmas. The muck has been used side by side with chemical manure, and the comparative value of the two can be seen at a glance, the dark green hue and vigorous growth of the crop treated with chemical manure affording a remarkable contrast to the weakly growth and pallid hue of that under muck, which in this instance contains little besides humus, as it had been the custom of the farmer from whom it was purchased to trample down all his Wheat straw in the yards with horses and a few store bullocks.

If the experiments tend to show which are the best manures to be used for pasture they will do good service as affording a basis upon which farmers may make calculations. But in turning the results to practical account due weight must be given to local peculiarities of soil and climate, and, too, the residue of manure left in the soil in autumn may only be available for next year's crop, according to the weather which prevails during winter. In the comparatively dry weather of recent winters the soil has not been washed as it is in a wet winter when, as Sir J. B. Lawes tells us, so much nitrogen passes away with the drainage water.

WORK ON THE HOME FARM.

As we write this note the weather continues unsettled, and showers of rain have been so frequent that roots, corn, and green crops have all

derived much benefit from them. In several instances we have seen Mangolds with about a three-quarter plant from early growth, where the rain has caused the remainder of the seed to germinate, and although the plant from this is late it has been left to fill up vacant spaces, but the roots will not be so large as those which grew earlier.

Mowing grass for hay has been kept somewhat in abeyance while the weather continued so unsettled, but the time has now come for this work to be done. Our remarks have in this matter somewhat of a local bearing, as we are aware that hay-making has been in hand for the past week or two in the south midland counties. If the weather continues unsettled due care must be taken to avoid having the hay much "washed" in the making. This is managed by putting in cocks as soon as it is about half harvested, then by the exercise of watchfulness it may be shaken out as opportunities occur in rows, and be kept moved by passing the tedding machine along each row, again putting it in cocks if the weather is doubtful. Extra precaution should be taken in a wet summer to prevent overheating in the hayricks. We manage this perfectly in a very primitive manner by making one or more air shafts in each rick to admit of a free escape of vapour by stuffing a sack with straw, building up the hay around it, and gradually drawing it to the top of the rick as the work goes on. Each evening before the men leave the work the stuffed sack is withdrawn from the shaft so as to allow the hot vapour to escape freely during the night. If hay can be made it is altogether preferable to any other food for cows and cattle, but if not, then it is well to have recourse to making silage, which can be done as easily in damp unsettled weather as in fine, provided the necessary amount of pressure can be applied to stack or pit. For farms generally it may prove to answer best to make a certain quantity of both hay and silage, because hay can always be sold if there is a surplus quantity on hand, and the silage be turned to account for home consumption. Where a pit silo is provided there is no doubt that chaffed silage of Maize, Sorghum, or other coarse herbage, affords an invaluable supply of nourishing food for winter use.

DR. VOELCKER ON MANURES.—At Dyson's Wood, on the occasion of inspecting the experiments above referred to, Dr. Voelcker, in reply to several speakers, said there were many problems yet to be worked out—one being the value of earlier application of certain manures as suggested by Mr. Wright. Mr. Sutton's experiments had been very useful to him personally. From his general experience he should certainly prefer a dressing of dissolved bones to one of steamed or boiled bones; and where it could be had farmyard manure was of the utmost advantage to grass lands, but it was not necessarily always the best, owing to variations in soils. To put the whole thing in a nutshell, he should advise chemical manures for cereal and root crops, and farmyard manure where it could be obtained for permanent grass crops, if the manure were properly made under cover. For temporary pastures, and these alone, he should advise the use of such things as nitrate of soda, but it must be used with due caution. Farmyard manure was especially valuable in giving staple to a soil, and to put nitrate of soda on a poor soil was not fair. They should use chemical manures for what they took out, when they had other necessary ingredients in the land already, and not to enrich or impoverish the soil. The most economical application of farmyard manure was certainly to land which was deficient in humus, or worked badly mechanically. If they once got the soil into organic condition they might use chemical manures for corn and root crops, and also on grass to a limited extent.

REMARKS.

24th.—Heavy rain in the small hours; damp and very oppressive morning; fine and hot afternoon.
25th.—Fine and very hot, but frequently cloudy.
26th.—Cloudy early; wet from 8 A.M. till nearly noon; high yellow fog for a short time at noon, after which it cleared, and there was some sunshine in the afternoon; thunder and lightning all the evening and night with heavy storms of rain.
27th.—Cloudy morning, wet afternoon all night.
28th.—Fine and generally bright in the morning; thunderstorm between 2 P.M. and 3 P.M.; then fair again.
29th.—Cool and frequently cloudy, with showers in the morning and in the evening.
30th.—Fair with occasional sunshine.
This week has afforded a good illustration of the libellous "typical English summer," three hot days and a thunderstorm. We had some heat on Sunday, Monday, and Tuesday, and after then it was thunder and rain till nearly the end of the week.—G. J. SYMONS.

* Falling before 9 A.M. the amount was, of course, entered in last week's table in accordance with the regular rule as to rainfall measurement.

FLOWERS are more extensively employed for decorative purposes in civilised countries at the present time than has ever been the case before, and amongst the Anglo-Saxon race on both sides of the Atlantic the increased attention paid to floral decorations has been most remarkable within quite recent years. In London alone the enormous quantities of flowers employed daily can scarcely be imagined, even by those who frequent Covent Garden Market, and to whom the thousands of boxes sent in from the provinces and the Continent at all times of the year afford a familiar sight. From the itinerant street purveyor's Roses or buttonholes at a penny each, or the modest 6d. and 1s. posies of the shops, to the elaborate bouquets or wreaths which the fashionable florists retail at a guinea and upwards, there is every gradation in merit and value to meet all tastes and purses. Growers complain that prices are low, but the purchasers increase in numbers, and flowers are no longer regarded as a luxury solely within the reach of the affluent. The majority are content with a simple vase or two decked with flowers and foliage to be renewed as frequently as means permit, and arranged as gracefully as the character of the material allows. In the homes of the wealthy floral decoration has, however, developed into an art of considerable importance, and whatever ingenuity can devise or tasteful skill can execute, to increase the diversity of attraction, is in demand.

Few of the leading exhibitions are deemed complete unless classes are specially devoted to floral decorations, and some societies have wisely appropriated a goodly share of their funds to the encouragement of what is invariably one of the most interesting and popular departments of a show. Not only do they furnish an important attraction, but they are also educational to a great extent, as amateurs who engage in such work for pleasure, and gardeners who include it amongst their duties, can always learn something at an exhibition where competition is keen in the floral classes. The value from this point of view depends to a great extent upon the care and consistency with which the awards are made, as some kind of guide is then furnished both to exhibitors and visitors. Of course as much latitude as possible must be allowed, and any attempt at restricting exhibitors within narrow limits would utterly defeat the objects in view, restrain originality, and induce a stereotyped style that is most to be avoided. Still, adjudicators ought to be able to determine some broad principles and adhere to them, as for instance whether simplicity or elaborateness, lightness or massiveness, are preferable. It is too often apparent that fancy rather than judgment decides these matters, and consequently dissatisfaction frequently and naturally arises.

The largest and most important exhibition of floral decorations in the metropolis is that held by the Royal Botanic Society in connection with their Evening Fête in the Regent's Park Gardens. This is one of the events of the London season, and though the gathering for the present year, held last week on the 4th inst., was not favoured by the best of weather, it attracted, as it invariably does, a large number of visitors. The large marquee employed for the Summer Shows was devoted to the table decorations, hanging baskets, groups for recesses or fireplaces, and groups of plants or cut flowers from various nurserymen; the long approach tent being occupied with bouquets, stands of flowers, &c. About twenty tables were displayed in the two

classes for them, and it can be imagined that considerable diversity of taste prevailed amongst so many, which was still further accentuated by a corresponding diversity in the awards. Some exhibitors had endeavoured to merit recognition by a light and graceful style of dressing the usual plain glass trumpet vases, others loaded the tables with massive crystal or china vessels, the flowers evidently constituting a secondary consideration. The simple unpretentious style was well represented by a table that did not secure a prize, wreaths of crimson, white, and yellow Roses lightly thrown on the cloth surrounding a basket of Roses and Stephanotis, with wicker-covered pots of *Rhynchospermum jasminoides* and Fern at the ends. One table, which gained the first prize in the class, was pleasingly decorated with Moss Roses, a few yellow Roses, *Odontoglossums* and *Adiantum* fronds, but there were rather too many stands, and it was marred by a curious piece of artificiality. Four small plain glass lamps had wire circles surrounding the chimneys upon which were laid Fern fronds and Roses as a shade. They were, however, quite useless for this purpose, as when the lamps were lighted anyone sitting at table would have had the glare full in their eyes, and the heat caused the Ferns to shrivel and the flowers to wither in quite a painful manner. An unusually heavy arrangement was placed second to this which can only be commended for the fact that the few flowers employed, chiefly Carnations, harmonised well. The light, graceful, and cloudy *Gypsophila paniculata* was freely employed in several instances, as were also the orange, yellow, and white varieties of *Papaver nudicaule*, with *Aquilegia chrysantha*, and two excellent arrangements of these flowers, with *Lygodium scandens* and *Adiantum*, were contributed, one gaining the third prize for Mrs. Sperling, and the other in Mr. Chard's best style, being passed by the Judges. The whole of those referred to were laid for dessert, and the selection of the fruit added materially to the beauty and finish of the arrangements.

The ordinary dinner tables without dessert were somewhat similar in characteristics and the flowers employed, but the winner of the first prize (Mr. W. C. Buster) displayed some originality in arrangement. In the centre was a tall glass trumpet vase containing at the top a few small white Campanulas, two or three pink Begonias, *Gypsophila*, and *Asparagus plumosus*; at the base the white variety of *Gladiolus Colvilli*, double pink Ivy-leaf *Pelargoniums* and Fern fronds. Two light side arches were covered with *Asparagus*, a few similar flowers to those in the vase, and a rich velvety wreath of *Cissus discolor*, small glasses being filled with Roses and *Pancratiums*. In the arrangement of flowers and foliage for a sideboard English and Spanish white and yellow Irises were general favourites in stands or bowls, while one exhibitor gained a prize for a "floral lyre" of Marguerites, pink Carnations, *Adiantum* and *Fittonia* leaves—rather too much of an artistic curiosity for many tastes.

The bouquets were numerous, and represented all gradations between the most elaborate and the most simple. One was selected as the best ballroom bouquet that possessed the merit of an informal arrangement, but there was an undue display of wire and a want of finish that detracted from its merits greatly. *Odontoglossum crispum*, *Gladiolus Colvilli albus*, Roses and Carnations were the principal flowers. Several of the other bouquets were preferred by many visitors to this, both for the material employed and the general finish—two essential points. The flowers for a bridal bouquet cannot be too pure, and however well they may be arranged the effect is spoiled if what may be termed the machinery is too plainly exposed. The second prize bouquet was better in both the respects mentioned, *Pancratiums*, *Eucharis Mastersi*, Roses, *Stephanotis*, and double *Tabernaemontana* constituted the principal flowers, which were placed together in a natural and free manner but not quite so irregularly as the first. Why another fine bouquet of the same character was passed unrecognised it would be hard to determine.

The most interesting class in this section was that for a ball-

room bouquet, and the eighteen competitors presented a sufficient diversity of styles to satisfy all tastes and fancies. The one selected for first honours was a most elaborate production, about 15 inches high from the paper, and 18 inches in diameter, a substantial load for a lady to hide herself behind. It was composed mainly of Cattleyas, with a few *Odontoglossums* and Fern fronds, and it must be admitted that the arrangement and making were admirable for such a large bouquet. In remarkable contrast to this was the second prize bouquet, rather less than half the size, formed of a few blush-tinted Roses, *Gladiolus Colvilli albus*, and *Adiantum* fronds, simple in the extreme, and elegant, but so totally dissimilar in all respects from the first, that it seemed strange, after honouring one bouquet distinguished by its elaborate style, several others of the same kind, and but few points inferior to the first, should be passed over. At the same time it is wise to encourage these smaller and more simple productions, and if the Judges had adopted the bold course of placing it first the awards would have been more consistent. One enormous and heavy bouquet was properly omitted, and why such fatiguing examples are shown cannot be understood, they would be enough to tire a strong-handed footman. A third prize was awarded to an exceedingly original example that could scarcely be termed a bouquet; it was really a loose bunch of Grasses and *Mignonette*, with a few flowers of double scarlet Zonal *Pelargoniums*, with streamers of scarlet and bottle-green ribbons. A pretty and simple bouquet was composed of *Mignonette* and Miss Jolliffe Carnations, and a loosely disposed bunch of crimson, yellow, and creamy Roses was attractive; another of crimson Roses and single yellow Briars was pleasing, and the only faults in still another handsome Rose bouquet was rather too much crowding and flatness.

Groups of flowers with the stalks in water, but neither tied nor wired, included several tasteful exhibits. The leading group composed of ten large pale pink and white *Pæonies* on long stems with plenty of foliage very naturally dispersed in a somewhat small stand. If the latter had been a little larger and bolder, more in proportion to the massive character of the flowers, it would have improved their appearance. Next to this was placed a neat basket suspended on a tripod and filled with *Gypsophila*, *Odontoglossums*, Roses, *Phalænopsis*, and *Asparagus*. One of the simple and graceful contributions (third prize) in this class was, however, a tall trumpet plain glass vase furnished with long drooping sprays of *Russelia juncea* bearing numbers of its tubular bright coral red flowers, and it was quite refreshing to see an old favourite, but now neglected plant, being utilised to the exclusion of the conventional decorative flowers.

At Richmond on the same day an excellent display of floral decorations was held, one of the three large tents being exclusively devoted to these classes, Roses and other cut flowers. It was rather unfortunate that the dates of these two Societies clashed, as it accounted in a great measure for the absence of competitors in the table decoration class in which such liberal prizes are offered by Lady Ellis. Numerous elegant stands and baskets of flowers were shown, but the bouquets were much overcrowded. In several cases the stands employed were not in accordance with the style of arrangement adopted, light tastefully placed flowers in a heavy stand, or *vice versa*, being a fault too often apparent at shows.—L. CASTLE.

INCREASING STRAWBERRY PLANTS.

WHEN Strawberry plantations are neglected their whole surroundings soon become crowded with runners, but this is not desirable, and should be avoided. Many of them are formed now, and by the time the fruit is all ripe and gathered they will be very numerous. It is then the cultivator should determine what he will do. If no new plants are wanted cut the young ones in close round the old stools or rows. But in the majority of cases young plants will be wanted, and these should be secured at once, either to pot for forcing in the spring months or to form new plantations. Great attention is often given to layering and raising the plants intended for forcing, but those for planting in the new quarters are

often lifted and planted without any preparation; but this is a mistake, as with proper care they will always bear a quantity of fruit the first year after planting, and I have known them bear heavily, whereas the carelessly reared ones seldom have any fruits worth gathering until the second year.

The best way is to layer each runner into a 3-inch pot. Place a few leaves or a little rough material at the bottom of each, then fill close to the rim with fibrous loam to which a little manure has been added, and make the soil very firm. Lift each runner suitable for layering from the ground, but do not break their connection with the old plant. Place the young plant on the surface of the soil in the pot, and if the roots have some of the soil of the ground attached let them into the soil in the pot, and layering in this case is completed. If the roots are only beginning to show secure the runner with a peg close to the neck of the young plant. The young roots will penetrate the new soil in a few days, and they will soon grow rapidly. In dry bright weather supply water daily, and when they have been layered ten days or so turn one or two of them out of the pots, and if the roots have taken a substantial hold of the soil cut them away from the plants, and collect them all together on a hard base, such as a walk. This is to prevent rooting through the bottom of the pots. The foliage will droop a little for a day or two, but this is harmless, and in a week or ten days after taking them off they will be ready for either potting or planting. We like to do both before the pots are filled with roots. When the roots are too numerous and in a firm ball the plants do not grow away freely if transferred to other soil.

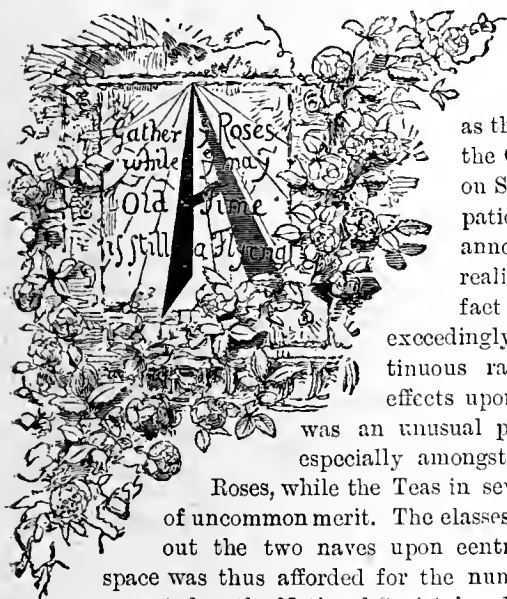

Another system is to cut fibrous turf into pieces about 4 inches square. They are turned upside down, and the young plants pegged on to them. The roots soon penetrate the turf and confine themselves to it. Such plants invariably grow well, and this plan is superior to that often adopted of allowing the runners to root into the ordinary soil. Many of the roots of these will be broken in lifting; some will have no soil attached to them, and all will receive a check which cannot occur with those in turves or pots.—J. MUIR, *Margam*.

SHRUBS SUITABLE FOR SEASIDE PLANTING.

THE publication of a few notes recently made of shrubs luxuriating on the seacoast in Hampshire, Dorsetshire, and North Devon, may prove useful to those of your readers who have to do with the planting and beautifying of bare spots, cliffs, or in seaside towns. In Bournemouth, and Boscombe Chine, close by, the green *Euonymus*, in some cases half buried in sea sand, does much better than the *Tamarix*, and is therefore planted extensively in the public and private gardens, also as hedges underneath the Pine trees on each side of the principal roads in Bournemouth. The pretty garden opposite the "Royal Victoria Hotel," Swanage, and close to the sea is completely enclosed by luxuriant hedges of the green and golden *Euonymus*, while a few hundred yards farther up the town the *Euonymus* and *Aucuba japonica*, planted in a garden attached to John Wesley's house, and sloping to the sea, are the picture of health. But nowhere have I seen such grand specimens of *Euonymus* as at Ilfracombe, many of the bushes being 9 feet high and as much through, within a hundred yards of the sea. In the grounds attached to St. James's Church there are several dozens of fine specimens. Another shrub, and this a flowering one, that does equally well at Ilfracombe, is *Escallonia macrantha*, trained up the south and west walls of "Hotel Ilfracombe" and other buildings of less importance throughout the town, as well as in bush form from 9 to 10 feet high and as much in diameter on the lawns in front of the several villa mansions on the south side of the steep cliffs in this picturesque North Devon town. The soil (red loam), as well as the climate of Ilfracombe, admirably suits the requirements of the shrubs indicated, also *Berberis Darwini* and *Weigela rosea*. The latter popular flowering shrub is grown extensively and well in several towns on the North Devon coast, including Lee, three miles west of Ilfracombe, and the latter favourite resort, Watermouth Castle, Combmartin, Lynton, and Lynmouth, in all of which places the *Weigela* is growing luxuriantly; the flowers, too, being more plentifully produced, larger, more substantial, and of a brighter hue than they are met with on places away from the sea. The Sea Buckthorn (*Hippophæ rhamnoides*) is also suitable for planting close to the sea, but the only place I have seen it growing is Tynninghame, the beautiful East Lothian residence of the Earl of Haddington, near Prestonkirk. There is quite a plantation of it near Whitberry Point, and within a few dozen yards of the German Ocean. The bright orange-coloured berries with which the Willow-like shoots are studded are very effective when contrasted with its silvery foliage. The salt spray with which the Sea Buckthorn is frequently washed has no injurious effect on it. Is it not surprising that it is not more frequently met with in the vicinity of fashionable watering places?—H. W. WARD.

NATIONAL ROSE SOCIETY.

JULY 7TH.

MOST extensive and highly satisfactory Exhibition for such a season as the present one was held at the Crystal Palace, Sydenham, on Saturday last. The anticipations which a correspondent announced last week were fully realised, notwithstanding the fact that the weather was exceedingly unfavourable. The continuous rain had left unpleasant effects upon many blooms, but there was an unusual proportion of fine flowers, especially amongst the dark-coloured H.P.

Roses, while the Teas in several leading stands were of uncommon merit. The classes were distributed throughout the two naves upon central tables, and abundant space was thus afforded for the numerous visitors invariably attracted to the National Society's exhibitions.

NURSERYMEN'S CLASSES.

The principal class in the Show was that for seventy-two blooms, distinct varieties, and the challenge trophy, value sixty guineas, with the first prize, was won by Mr. Frank Cant of Colechester, whose fine collection well deserved the coveted honour. Rarely have neater or more finished blooms been staged by this exhibitor. The Teas were exquisite, and the H.P.s remarkable for freshness and purity of colour. Mr. Cant is to be heartily congratulated. The following varieties were represented:—Back row: Madame I. Pereire, Charles Lefebvre, Alphonse Soupert, Marie Baumann, Pride of Waltham, Prince Arthur, Duchesse de Morny, Prince Camille de Rohan, Madame Eugene Verdier, Ulrich Brunner, Her Majesty, A. K. Williams, La France, Crown Prince, François Michelin, Général Jacqueminot, Heinrich Schultheis, Earl of Pembroke, Souvenir d'un Ami (very fine), Louis Van Houtte, Captain Christy, Dr. Andry (a beautiful bloom), Merveille de Lyon, and Duke of Edinburgh. Middle row: Madame Ducher, very bright and fresh; Etienne Levet, Duke of Connaught, Souvenir de la Malmaison, Charles Darwin, Maréchal Niel, Sultan of Zanzibar, Annie Laxton, Exposition de Brie, Niphetos, Thos. Mills, Souvenir d'Elise, Alfred Dumesnil, Marie Van Houtte, Countess of Rosebery (both splendid), Mrs. John Laing, Duke of Teck, Madame Lambard, Countess of Oxford, Madame Gabriel Luizet, Dupuy Jamain, Baroness de Rothschild, Madame Alphonse Lavallée, and Mat Baron. Front row: Pride of Reigate, E. Y. Teas, Auguste Rigotard, Horace Vernet (very fine), Madame Bravy (splendid), Le Havre, Catherine Mermet, Glory of Cheshunt, Madame de Watteville, Duke of Wellington, Duchess of Edinburgh, Camille Bernardin, Rubens, Alfred Colomb, Madame Cusin, Victor Hugo, Viscountess Folkestone, Abel Carrière, Jean Ducher, Fisher Holmes, Marie Verdier, Duchess of Bedford, M. Noman, and Rosieriste Jacobs. Very fine also was the second prize lot of Messrs. Paul & Son, The Old Nurseries, Cheshunt. Such varieties as Paul Neyron, A. K. Williams, Charles Lefebvre, François Michelin, Ulrich Brunner, Mrs. Chas. Wood, and Général Jacqueminot were magnificently shown, and there were good examples of many other popular varieties. Mr. Cant's victory was not gained without a close struggle. Mr. B. R. Cant of Colchester took third place with a most meritorious collection, and Messrs. John Cranston, King's Acre Nurseries, Hereford, were fourth. From the collection of the last named exhibitor was selected the best Hybrid Perpetual in the Show, an example of Etienne Levet which has perhaps been rarely equalled before. This superb bloom was 6 inches in diameter, deep, massive, perfect alike in form and colour. There were five exhibitors in this class.

In class 2, forty-eight distinct varieties, three blooms of each, there were four competitors, and Mr. B. R. Cant improved on his previous display by securing the premier honours. With but few exceptions the blooms were remarkably neat and fresh, and bore the finish invariably distinguishing the exhibits of this famous exhibitor. The varieties shown are enumerated. Back row: Charles Lefebvre, Merveille de Lyon, A. K. Williams, Souvenir d'un Ami, Prince Camille de Rohan, Madame E. Verdier, Horace Vernet, Madame Gabriel Luizet, Marie Baumann, Heinrich Schnltheis, Duke of Edinburgh, Duchesse de Morny, Sénateur Vaisse, Marie Verdier, Xavier Olibo, La France, Dr. Sewell, Baroness Rothschild, Dupuy Jamain, Etienne Levet, Général Jacqueminot, Madame C. Joigneaux, Louis Van Houtte, and Madame I. Pereire. Front row: John Hopper, Alfred Colomb, Mrs. John Laing, Madame Ducher, Souvenir d'Elise, Duke of Wellington, Madame Lambard, Maurice Bernardin, Marie Van Houtte, Ulrich Brunner, Niphetos, Victor Hugo, Catherine Mermet, Reynolds Hole, Madame Cusin, Prince Arthur, The Bride, Alfred Dumesnil, Violette Bouyer, Fisher Holmes, Innocente Pirola, Sultan of Zanzibar, Madame Bravy, and Thos. Mills. Messrs. Paul & Son, Cheshunt, were second. Some remarkably fine

blooms were observable in their stands, notably Ulrich Brunner, Charles Lefebvre, Duke of Edinburgh, A. K. Williams, and François Michelin, but many of the light coloured flowers were somewhat weak. Mr. Frank Cant was third, and Mr. Charles Turner of Slough fourth. There was not much to choose between these two.

Class 3, forty-eight single trusses, proved to be the most popular of all in the nurserymen's section, seven competing, and was highly interesting, producing in the first prize collection of Mr. William Rumsey, Waltham Cross, one of the freshest, neatest and most generally creditable collections of blooms that have been seen at any of the National Society's shows. Here and there a bloom might be observed that was a little past its best, but the majority were perfect. The varieties represented were as follows:—Back row—Ulrich Brunner, a really beautiful bloom; Lady Mary Fitzwilliam, Madame Nachury, Charles Lefebvre, La France, Sir Garnet Wolseley, Mdlle. E. Verdier, Duke of Edinburgh, Countess of Rosebery, Duchesse de Caylus, Madame Sophie Fropot, Prince Arthur, Merveille de Lyon, François Michelin, A. K. Williams, very fine; and Baroness Rothschild. Middle row:—Comtesse de Serenye, J. S. Mill, Le Havre, Catherine Mermet, Dr. Andry, Helen Paul, Hippolyte Jamain, Duchess of Bedford, Benoit Comte, Queen of Queens, Etienne Levet, Her Majesty, Xavier Olibo, Alfred Colomb, Pierre Notting, and Madame I. Pereire. Front row:—Lord F. Cavendish, Duke of Connaught, Duchesse de Morny, Harrison Weir, Général Jacqueminot, Lord Macaulay, Madame Gabriel Luizet, Eclair, Marie Verdier, Madame V. Verdier, Alba Rosea, Star of Waltham, Heinrich Schultheis, Camille Bernardin, Grace Darling, and Louis Van Houtte. Second place was taken by Messrs. J. Jefferies & Son, Cirencester, their Duke of Albany was a splendid bloom; Jean Ducher and Madame Clemence Joigneaux were also good, but the blooms generally lacked the freshness of the first prize stand. Messrs. G. Cooling and Sons, Bath, were an excellent third. The remaining prize fell to Mr. G. W. Piper, of Uckfield.

A collection of moderate excellence from Messrs. G. & W. H. Burch, Peterborough, secured the premier award in the class for twenty-four distinct varieties, single trusses. The varieties were:—Back row: Etienne Levet, Grace Darling, Camille Bernardin, Magna Charta, Xavier Olibo, Her Majesty, Harrison Weir, and Madame Eugene Verdier. Middle row: Madame Gabriel Luizet, Comtesse d'Oxford, Niphetos, Ulrich Brunner, Comtesse de Serenye, Heinrich Schultheis, Souvenir de Paul Neyron, and Exposition de Brie. Front row: Sénateur Vaisse, Marie Van Houtte, Louis Van Houtte, Innocente Pirola, François Michelin, Lady Mary Fitzwilliam, Marie Baumann, and Jean Ducher. Mr. G. Mount, Rose Nurseries, St. Dunstons, Canterbury, followed with Marie Baumann, La France, Camille Bernardin, and Alfred Colomb amongst his best blooms. Third place was taken by Mr. John House, Eastgate Nurseries, Peterborough, and fourth by Mr. J. Mayo, St. Mary's Road Nursery, Oxford. There were six competitors.

Class 5 was provided for three trusses each of twenty-four distinct varieties, and the winning stand came from Mr. G. Prince, 14, Market Street, Oxford, who showed in excellent form. The varieties in the back row were Grace Darling, Alba Rosea, A. K. Williams, The Hon. Edith Gifford, Comtesse de Nadaillac, Ulrich Brunner, Captain Christy, E. Y. Teas, Baroness Rothschild, Duke of Edinburgh, Merveille de Lyon, and François Michelin; those in the front Catherine Mermet, Earl of Pembroke, La France, Madame C. Joigneaux, Madame Gabriel Luizet, Anna Ollivier, Auguste Rigotard, Marie Van Houtte, Marie Verdier, Lady Mary Fitzwilliam, Princess of Wales, and Viscountess Folkestone. Messrs. J. Jefferies & Son followed, their best blooms being La France, François Michelin, Lady Mary Fitzwilliam, and Madame Gabriel Luizet. Messrs. Cooling & Sons were third, and Mr. John House fourth. Six competed.

AMATEURS' CLASSES.

Though considerable inequality was observable in the merit of the exhibits in these classes, the general quality far exceeded what could have been expected after such unfavourable weather. Plenty of damaged blooms were seen, but where they had escaped the storms remarkable examples were observable, of the dark varieties especially, size, substance, and colouring being admirable. There was, however, a prevailing tendency to coarseness, and few succeeded in making up a box of good blooms all through, even in the small classes. This rendered the few exceptions the more noticeable, and one of the finest collections of blooms in the Exhibition was that which secured for the year R. N. G. Baker, Esq., Heavitree, Devon, the Amateurs' Challenge Trophy, value 60 guineas, and the first prize in the class for forty-eight, distinct, single trusses. These were of good substance, clean, and richly coloured, the varieties being as follows, taking them from left to right. Back row: Centifolia rosea, Ulrich Brunner, Captain Christy, Etienne Levet, Duke of Edinburgh, Merveille de Lyon, Comtesse d'Oxford, A. K. Williams, Hippolyte Jamain, Alfred Colomb, Duc de Montpensier, Marquise de Castellane, Marie Baumann, Mdlle. Marie Rady, Charles Lefebvre, and François Michelin. Middle row: Madame Victor Verdier, Prince Camille de Rohan, Marshall P. Wilder, La France, Madame Marie Verdier, Lady Sheffield, Gloire de Bourg la Reine, Thomas Mills, Madame Alphonse Lavallée, Madame Eugene Verdier, Dupuy Jamain, Sultan of Zanzibar, Auguste Rigotard, Baroness Rothschild, Dr. Andry, and Duke of Wellington. Front row: Abel Grand, Comte de Raimbaud, Mrs. Laxton, Charles Darwin, Duke of Teck, Jean Soupert, Marguerite de St. Amand, Reynolds Hole, Camille Bernardin, Prince Arthur, Général Jacqueminot, Madame Gabriel Luizet, E. Y. Teas, Villaret de Joyeuse, Louis Van Houtte, and Beauty of Waltham. Of the five other competitors, W. G. Grant, Esq., Ledbury, Hereford, was second, his blooms

seeming to have suffered more severely in the stormy weather, but the specimens of Ulrich Brunner, Prince Arthur, Alphonse Soupert, and Duchesse de Morny were excellent. A. Slaughter, Esq., Jarvis Villa, Steyning, was third, and T. B. Hall, Esq., Larchwood, Rockferry, was fourth.

Only four stands of twenty-four varieties, three trusses each, were staged, Mr. R. N. G. Baker again leading with bright good examples of the undermentioned in two rows. Back row: Ulrich Brunner, Duke of Edinburgh, Merveille de Lyon, Madame Victor Verdier, François Michelin, La France, Prince Camille de Rohan, Etienne Levé, A. K. Williams, Marquise de Castellane, Charles Lefebvre, and Alfred Colomb. Front row: Auguste Rigotard, Madame Eugène Verdier, Général Jacqueminot, Mlle Marie Verdier, Thomas Mills, M. E. Y. Teas, White Baroness, Mlle Marie Rady, Madame Gabriel Luizet, Dr. Andry, Marie Baumann, Duke of Wellington. Mr. W. G. Grant was second, blooms of Dupuy Jamain and Duke of Edinburgh being very notable. Mr. S. P. Budd, Bath, and Mr. A. Slaughter followed with smaller blooms.

There was the same number of exhibitors in Class 8 for thirty-six single trusses, Mr. J. Ridout, gardener to T. B. Haywood, Esq., Woodhatch Lodge, Reigate, winning first honours with an excellent collection, in which the blooms were distinguished by their good colour. The varieties were arranged in this order—Back row: Mrs. Baker, A. K. Williams, Madame I. Percire, Captain Christy, Etienne Levé, Mrs. J. Laing, Marie Baumann, Lady Mary Fitzwilliam, Comtesse d'Oxford, La France, Horace Vernet, and François Michelin. Middle row: E. Y. Teas, Madame Gabriel Luizet, Louis Van Houtte, Madame Marie Verdier, Alfred Colomb, Duke of Bedford, Mlle Eugène Verdier, Mlle Marie Rady, Dr. Hogg, The Bride, and Général Jacqueminot. Front row: Comtesse d'Oxford, Ferdinand Lesseps, Dupuy Jamain, Mrs. Laxton, Charles Lefebvre, Princess of Wales, Devienne Lamy, Xavier Olibo, Duchesse de Caylus, Richard Laxton, Earl of Pembroke, and Lord Macaulay. Mr. E. B. Lindsell, Bearton, Hitchin, was second, Devoniansis, A. K. Williams being uncommonly good, but others had suffered materially. Mr. J. Brown, gardener to Mrs. Waterlow, Great Doods, Reigate, was third, and Mr. Harrington, gardener to E. Mitchell, Esq., Corbets Fey, Romford, was fourth.

Mr. Ridout was again successful in class 9 for eighteen distinct varieties, three trusses each, the blooms being as notable for their colour as in the preceding class. These were as follows—Back row: Madame Gabriel Luizet, Sénateur Vaisse, Lady Mary Fitzwilliam, A. K. Williams, Captain Christy, Etienne Levé, Marie Baumann, Mlle Marie Finger, and Alfred Colomb. Front row: M. E. Y. Teas, Madame Lambard, Horace Vernet, Mlle Marie Verdier, Louis Van Houtte, François Michelin, Xavier Olibo, Comtesse d'Oxford, and Général Jacqueminot. Messrs. Lindsell and Brown were second and third, the fourth prize being withheld.

Seven stands of twenty-four varieties, single trusses, were staged in Class 10, Mr. R. E. West gaining premier honours for fresh and admirable blooms rather more even in quality than in most other classes. The varieties were—Back row: Etienne Levé, Duke of Edinburgh, Captain Christy, Maurice Bernardin, Dupuy Jamain, Charles Lefebvre, Camille Bernardin, and Madame I. Percire. Middle row: Sénateur Vaisse, Marie Verdier, Comte Raimbaud, extremely fine; François Michelin, Marie Baumann, Madame Gabriel Luizet, A. K. Williams and one incorrectly named Duke of Wellington. Front row: Countess of Rosebery, Innocente Pirola, Duke of Teek, Louis Van Houtte, Dr. Andry, Xavier Olibo, Her Majesty, and Prince Camille de Rohan. The Rev. H. A. Berners, Harkstead Rectory, Ipswich, was second with neat blooms of Horace Vernet, A. K. Williams, Duke of Edinburgh, and Mlle Marie Verdier. The Rev. A. Foster-Melliar, Sproughton Rectory, Ipswich, was third; and Mr. J. Gurney Fowler, Woodford, was fourth.

Amongst four exhibitors of twelve varieties, three trusses each (Class 11) Mr. R. E. West continued his success, and won the first prize for substantial blooms, some of which were rather weather-beaten. The varieties were Etienne Levé, Marie Baumann, Louis Van Houtte, La France, Dr. Andry, Duke of Edinburgh, Madame Victor Verdier, Madame Gabriel Luizet, A. K. Williams, François Michelin, Général Jacqueminot, and Le Havre. The Rev. A. Foster-Melliar; Mr. H. Evans, Marston, Oxon; and Mr. G. Christy, Westerham, followed in that order.

Class 12 was provided for eighteen distinct varieties, single trusses, and the nine stands shown made a good display. Mr. M. H. Foster, Ashford, Kent, was first for a beautiful collection comprising very fine blooms of dark varieties. Back row: Marguerite Brassac, Duke of Edinburgh, Dupuy Jamain, Marie Baumann, Captain Christy, and Ulrich Brunner. Middle row: Mlle Marie Verdier, A. K. Williams, Baroness Rothschild, Duke of Wellington, Madame Victor Verdier, and Empress of India. Front row: Eugène Fürst, Madame Lambard, Pride of Ashford, Bouquet d'Or, Prince Camille de Rohan, and Rubens.

The competition was also keen in Class 13, for twelve distinct, single trusses, eight boxes being shown. The Rev. Alan Cheales, Brockham Vicarage, Surrey, was adjudged first honours for an effective stand of the undermentioned varieties, the blooms fresh, and with one or two exceptions, of moderate size. Back row—Camille Bernardin, wonderfully handsome, unusually large, and first rate in substance and colour, well deserving the silver medal awarded it as the best H.P. in the amateurs' classes; A. K. Williams, Duke of Edinburgh, and Etienne Levé. Middle row—Beauty of Westerham, Marie Baumann, La France, and Alfred Colomb. Front row—Duke of Wellington, Dupuy Jamain, Madame Victor Verdier, and E. Y. Teas. Lieut-Col. F. Standish Hore, St. Asaph, secured the second place; Mr. H. Wallis, Cornsland,

Brentwood, and Mr. R. L. Knight, Sittingbourne, were third and fourth respectively.

With nine varieties the Rev. T. S. Taylor, Littleton Vicarage, Evesham, was placed first, his varieties being Ulrich Brunner, La France, and Mlle Marie Verdier in the back row; Maréchal Niel, Camille Bernardin, and Charles Lefebvre in the middle row; and Madame Gabriel Luizet, Madame Lambard, and Baroness Rothschild in the front row. The six other stands mostly contained small blooms. Mr. C. E. Cuthell, Chapel Croft, Dorking, and Mr. L. C. Times, Hitchin, secured the remaining prizes. Five boxes of six varieties were entered, Mr. F. E. Coleby, Rosenheim, Worple Road, Wimbledon, leading with Comtesse d'Oxford, La France, Pauline Talabot, Ulrich Brunner, Victor Verdier, and Louis Van Houtte. The Rev. E. G. King, Madingley Vicarage, Cambridge; Mrs. Ponsford, Wray Park, Reigate; and Mr. G. Crofts, gardener to W. D. Freshfield, Esq., Parkside, Reigate, followed in the order named. Mr. H. Foster had the best six triplets, comprising: Duke of Edinburgh, Madame Gabriel Luizet, A. K. Williams, Ulrich Brunner, Marie Baumann, and Dupuy Jamain. The Rev. Alan Cheales was a good second; Mr. C. E. Cuthell and Mr. W. Narroay, Oxford, taking third and fourth places amongst seven competitors.

EXTRA CLASSES.

Most of these were small classes, the competition moderate except in one case. For six blooms from amateurs who had never won a prize at the National Society's Shows Mr. Percy Burnand, Reigate, won the premier award with very creditable examples of Marie Baumann, Duchess of Bedford, Auguste Rigotard, Duke of Edinburgh, Etienne Levé, and Ulrich Brunner. Mr. G. Moules, Sun Street, Hitchin, was second; Mr. W. J. Dart, Melrose Villa, Heathfield Road, Croydon, and Mr. H. V. Machin, Gateford Hall, Worksop, won the other prizes in that order, most of the blooms shown being of fair merit. There were five competitors in that and the following class for six varieties grown within eight miles of Charing Cross. Mr. W. Northover, 20, Queen's Road, Wimbledon, won the leading prize with excellent blooms of Louis Van Houtte, Charles Lefebvre, Dr. Andry, Marie Baumann, Comte Raimbaud, Général Appert. Mr. Coleby, Mr. G. Barker, Blackheath, and Mr. G. A. Marshall, 7, Seymour Villas, Anerley, were second, third, and fourth for satisfactory blooms. Only one stand of six new varieties was shown, Mr. T. W. Girdlestone, Sunningdale, Berks, winning first honours for neat blooms of Souvenir de Gabrielle Drevet, Clara Cochit, Silver Queen, Souvenir de Victor Hugo, Victor Hugo, and Mrs. John Laing.

The competition was very keen in Class 20 for six trusses of any Hybrid Perpetual Rose, fourteen boxes being staged. Mr. T. B. Hall, Larchwood, Rockferry, won the premier prize for fresh, substantial, handsome examples of Madame Gabriel Luizet. Mr. W. J. Grant won second for even bright blooms of A. K. Williams. Mr. G. Christy followed with Duke of Edinburgh, very rich in colour; and Mr. E. P. Budd was fourth for Ulrich Brunner; the Rev. F. Page Roberts having an unrecognised but admirable stand of Dupuy Jamain.

Class 21 was for twelve blooms, six of any H.P. and six of any Tea. Mr. A. Slaughter had the best of the half-dozen exhibits, fine blooms of Général Jacqueminot and Marie Van Houtte. Mr. W. J. Grant had the second place with A. K. Williams and Marie Van Houtte; the Rev. F. Page Roberts being third for the same two varieties.

TEA AND NOISETTE CLASSES.

The effects of the dripping weather were more apparent on these delicate blooms than on their larger, stronger, and darker congeners, the H.P.'s.

Class 22, twenty-four blooms, distinct.—In this class of four stands Mr. G. Prince well won the first position with Alba Rosea, good; Catherine Mermet, Princess Beatrice, a charming soft yellow bloom; Anna Ollivier, Niphetos, Sunset, Hon. E. Gifford, Comtesse de Nadaillac, handsome; Madame C. Kuster, Amazone, Cornelia Koch, Souvenir d'un Ami, Rubens, Marie Van Houtte, Jules Finger, Innocente Pirola, Madame Cusin, The Bride, Madame Lambard, good; Souvenir de S. A. Prince, the fine sport from Souvenir d'un Ami, Princess of Wales, Maréchal Niel, Adam, and Jean Ducher. Mr. B. R. Cant was second with an even stand, Madame Lambard and Catherine Mermet being the best blooms. Third, Mr. Frank Cant with neat medium blooms. Fourth, Mr. G. W. Piper, Uckfield, smaller, but cleaner.

Class 23, eighteen distinct trusses, seven excellent stands. The premier position was won by Mr. J. Mattock with Comtesse de Nadaillac, Madame Bravy, Souvenir d'Elise, Madame Willermoz, Catherine Mermet, Jean Ducher (silver medal, fine), Madame Welch, Souvenir d'un Ami, Madame C. Kuster, Madame Lambard (very rich), Innocente Pirola, Princess Olga, Amazone, Devoniansis, Souvenir de Madame Pernet, Hon. Edith Gifford, Marie Van Houtte, and Cornelia Koch. Mr. G. Mount, Canterbury, was a very good second, Messrs. Keynes & Son a close third, with the cleanest blooms of all, and Mr. C. Turner fourth.

Class 24, twelve blooms of any one variety. First, Mr. G. Prince, with excellent full blooms of Hon. Edith Gifford. Mr. B. R. Cant second with Catherine Mermet, Mr. C. Turner third (very close) with the same variety, and Mr. F. Cant fourth with Souvenir d'un Ami. Six stands.

In Class 25, for eighteen Teas or Noisettes, three trusses of each, Mr. G. Prince won the chief position with good examples of Alba Rosea, Comtesse de Nadaillac, Rubens, Souvenir de G. Drevet, Anna Ollivier, Niphetos, Souvenir d'un Ami, and The Bride. Mr. Frank Cant was an exceedingly close second, with fresher and cleaner blooms as a rule, but some rather small; Madame Willermoz was particularly fine, and Madame Lambard, Rubens, and Madame Cusin very good indeed. Third honours

fell to Mr. B. R. Cant, with blooms still a little smaller, Madame Lambard the gem of the stand. Mr. J. Mattock, Oxford, had the remaining prize with fresh neat blooms. Five competitors.

Six of the classes for Teas and Noisettes were devoted to amateurs, and a very satisfactory portion of the Show these constituted, as the competition was keen, and the blooms, in the majority of cases, much superior to what could have been expected, even by the most sanguine. In Class 26, for eighteen distinct, single trusses, there were ten exhibitors. The Rev. F. R. Burnside, Chipping Campden, took first place for a charming collection of fine blooms. Back row: Catherine Mermet, Madame Lambard, Innocente Pirola, Madame Cusin, Rubens, and Jean Dueber. Middle row: Anna Ollivier, Marie Van Houtte, Souvenir de Gabrielle Drevet, The Bride, Souvenir d'un Ami, and Caroline Kuster. Front row: Madame de Watteville, Edith Gifford, Jules Finger, Maréchal Niel, Madame Bravy, and Comtesse de Panisse. The Rev. F. Page Roberts was second with fine blooms not many points behind the first. Mr. W. J. Grant was third, and the Rev. H. A. Berners fourth, both showing well.

The premier box of twelve varieties came from Mr. R. L. Knight, beautifully fresh blooms of Madame Cusin of remarkable substance and colour, which gained the silver medal as the best Tea in the amateurs' classes, Madame Bravy, Catherine Mermet, Niphetos, Innocente Pirola, Souvenir d'un Ami, Marquis de Sanima, Devoniensis, Souvenir de Paul Neyron, Marie Van Houtte, Comtesse de Nadaillac, and Comtesse Riza du Parc. Mr. O. G. Orpen, Colchester, Rev. J. H. Pemberton, Romford, Mr. J. Brown, and Mr. E. Mitchell secured the other prizes, the two last named being equal fourth, only one stand out of the six being thus unrecognised by the Judges.

The Rev. L. Garnett, Chester, led with nine Teas in Class 28, showing Madame Cusin, Innocente Pirola, Jules Finger, Madame Bravy, Madame Caroline Kuster, Princess of Wales, Catherine Mermet, Hon. E. Gifford, and Francisca Kruger. Mr. F. Baker was second, Mr. W. Narroay third, and Mr. R. G. Tucker, Swanley, fourth. The Rev. F. S. Taylor, Evesham, had the best box of six Teas—namely, Souvenir de Paul Neyron, Maréchal Niel, Souvenir d'un Ami, Madame Lambard, Catherine Mermet, and Marie Van Houtte, excellent blooms every one. Lieut.-Col. Standish Hore, Mr. C. E. Cuthell, and the Rev. Alan Cheales followed in the order named. (Five exhibits.) The Rev. F. R. Burnside secured the principal prize for twelve Teas, three trusses each, with fine examples of Innocente Pirola, Jules Finger, Caroline Kuster, Madame Cusin, Anna Ollivier, Souvenir de Gabrielle Drevet, Madame Lambard, Madame Bravy, Catherine Mermet, Maréchal Niel, Rubens, and Hon. Edith Gifford. Rev. H. A. Berners, who had the second place, showed good blooms, but slightly damaged by the weather. Mr. A. Slaughter was third, and the Rev. F. Page-Roberts fourth. (Four exhibits.) Class 31 was for six blooms of any Tea or Noisette, and this brought nine competitors. The Rev. Foster-Melliar was first with Marie Van Houtte, excellent; Mr. R. G. Tucker second for Madame Lambard; Mr. Mitchell third with Triomphe de Rennes, and the Rev. H. A. Berners fourth with the Hon. Edith Gifford.

OPEN CLASSES.

The first twelve of the series of classes were for twelve blooms of specified varieties as follows:—Any yellow Rose except Maréchal Niel, five competitors. First Mr. G. Prince for Comtesse de Nadaillac, handsome clean substantial blooms. Second Mr. F. Cant for the same variety, and third Mr. B. R. Cant with Marie Van Houtte. Any white Rose except Niphetos, ten exhibitors, seven showing Merveille de Lyon. First Mr. S. P. Budd with beautiful examples of that variety. Second Messrs. Paul & Son for The Bride. Third Mr. B. R. Cant with Merveille de Lyon. Any crimson Rose except Marie Baumann or A. K. Williams, eleven competitors. First Mr. B. R. Cant with Duke of Edinburgh of exceptionally rich colour. Second Mr. C. Turner with Camille Bernardin. Third Mr. F. Cant for Duke of Edinburgh. Any dark velvety crimson Rose, five exhibitors. First Mr. C. Turner with Prince Arthur, of fine shape, substance, and colour. Second Mr. B. R. Cant for Prince Camille de Rohan, and third Messrs. Paul & Son for the same variety.

Maréchal Niel was only represented by one box from Mr. B. R. Cant, which was awarded the third prize. Six boxes of Marie Baumann were contributed, Mr. C. Turner leading with twelve capital blooms, Mr. G. Mount and Mr. B. R. Cant taking the second and third places. Mr. G. Prince had the finest box of Lady Mary Fitzwilliam, followed by Messrs. Harkness and Turner. Of the eight stands of A. K. Williams Mr. B. R. Cant's was the best, Messrs. F. Cant and J. Cranston & Co. taking second and third prizes.

Mr. B. R. Cant was the solitary exhibitor with twelve single trusses of Niphetos, and was awarded the first prize for moderately good examples. Messrs. Paul & Son of Cheshunt were to the fore with a similar number of Her Majesty, comprising several good and some moderate blooms.

In Class 42, twelve single trusses of any new Rose except Her Majesty, Messrs. Paul & Son were again successful, showing the very promising Mrs. John Laing, the blooms, however, had suffered from the rain. In form this Rose is excellent, and the colour is a pleasing soft pink. Mr. B. R. Cant followed with The Bride, a Tea with a delicate lemon shade and rosy suffusion, Mr. Prince being third with the same variety.

Two exhibitors entered the class for twelve new Roses, Messrs. Paul & Son securing first honours for Comte de Paris, Her Majesty, Madame Henry Pereire, Mrs. John Laing, Madame Norman Neruda, Lady Helen Stewart, Lady Alice, Madame Baulot, Victor Hugo, The Bride, Grand Mogul, and Madame Massicault. Mr. B. R. Cant was

second, his best blooms being Lady Helen Stewart, Gloire de Margottin, and The Bride. No award was made in the class for three trusses of any new seedling Rose or sport not in commerce, but Mr. G. Prince had examples of the white Souvenir de S. A. Prince, previously noted in this Journal.

Collections of "garden Roses" comprised some interesting and attractive exhibits. Messrs. Paul & Son of Cheshunt were first, exhibiting Paqueritte, Vivid, Reine Olga de Wurtemberg, W. A. Richardson, Polyantha Simplex, Commandant Beaurepaire, Rugosa alba, Chas. Lawson (H.C.), Muscosa japonica, Mrs. Bosanquet (Ch.), Russelliana, Macrantha, Polyantha, Madame Cecile Brunner, Fulgens, Gloire de Dijon, and Dominal Boccard. Messrs. Bunyard was second, and the Rev. J. H. Pemberton third. The conditions specified that all H.P.'s were to be entirely excluded, also Teas and Noisettes, included as exhibition Roses in the National Rose Society's catalogue. Mr. House was unfortunate enough to violate the conditions and was disqualified.

Messrs. Bunyard & Co. were successful with twelve bunches of Moss and Provence Roses, Mr. House being second and Mr. Paul third. The first named showed Blanche Moreau (Moss), Little Gem (Moss), The Common Moss, Salet (Moss), White Bath (Moss), Larei (Moss), Reine Blanche (Moss), Celine (Moss), Common Provence, Cristata (Provence), Unique (Provence), and the Crested Moss.

The class for twelve Roses suitable for buttonholes was a very interesting one, the eight collections shown including some charming buds. Mr. J. Mattock was first, his stand including Marie Van Houtte, Rubens, W. A. Richardson, Jean Vernet, Amazone, Homère, Ma Cupucine, Anna Ollivier, Madame Lambard, and Safrano. Messrs. Paul and Bunyard were respectively second and third, showing similar varieties.

MISCELLANEOUS.

Messrs. Dobbie & Co., Rothesay, N.B., sent an extensive and beautiful collection of Pansies and Violas, also excellent Sweet Williams, and the dense crowd that flocked round the exhibit was the measure of its attractiveness. A finer contribution of its kind has not been seen in the south for many a day.

Mr. Edgar Newton had on view his patent system of dry glazing, which was closely inspected and approved by many practical horticulturists. His new system of ventilation was attached to the small structure, and for ease and regularity of working it is not easy to see how it can be surpassed, and it possesses the further merit of cheapness with simplicity. It is provisionally protected for patent. The adaptability of corrugated iron sheeting with ventilators for the sides of houses was shown, the exhibitor finding it cheaper than boards for the purpose. Houses of this kind must be well suited for Peaches and other fruits, including Tomatoes, also for Roses and Chrysanthemums, indeed for everything to which full light is essential for bringing out colour and quality.

A box of A. K. Williams Rose, fairly good, was exhibited by Mr. John House, who also showed W. A. Richardson, and had a further exhibit of Strawberries. These represented cut fruits and fruiting plants of two and three years planting.

Mrs. Chaff, Park Hill Nursery, Croydon, exhibited hand and dress bouquets of Roses.

Messrs. H. Cannell & Sons, Swanley, had large groups of Tuberous Begonias, representing the best of their varieties effectively arranged.

Mr. T. Francis Rivers, Sawbridgeworth, exhibited a remarkable collection of fruit trees in pots, and several fine dishes of Peaches, Nectarines, Cherries, and Plums, most of the varieties being of his own raising. Nectarine trees 3 feet high, in 8-inch pots, were each bearing upwards of a dozen splendid fruit, some of the Peaches in 9-inch pots having even more handsome specimens; while a tree of Guigne Annonay, a fine early black Cherry in a 12-inch pot, was a marvel of culture. It contained dozens of heavy clusters that, if gathered, would have more than filled a half-bushel basket. Mr. Rivers' packing must be equal to his cultural resources, for the trees had not a leaf or fruit injured. They attracted crowds of visitors. The dishes of fruit, comprised of Peaches, Galande, Damar, Early Silver, and some large unnamed seedlings; of Nectarines, Dryden, Newton, larger and better in colour than Lord Napier, which was good; Pine Apple, Otway, reddish orange; Stanwick Elruge and the rich Goldoni; Cherries, Early Rivers, black, very fine, and Bigarreau de Schreken, also black and splendid. When such fruits are produced by trees in pots in a plain cool house with rough boarded sides and a glazed roof, it is a matter of surprise that they are not more common in gardens. A dish of the Curlew Plum also merits notice—a medium-sized bluish purple fruit, and the tree as constant in bearing as the Early Prolific, and that is sufficient, because it scarcely ever fails. This collection of fruit was quite a feature of the Exhibition.

Messrs. Sutton & Sons, Reading, offered three prizes for specimens of Melons Imperial Green Flesh, Scarlet Invincible, or Hero of Lockinge. Mr. W. Palmer, gardener to W. F. Dick, Esq., Thames Ditton, was first with a fine fruit of Hero of Lockinge, Mr. C. J. Waite, Glenburth Gardens, Escher, being second. The same firm also offered prizes for two dishes of Peas, and Mr. Waite won the first award.

Messrs. J. Carter & Co., High Holborn, offered prizes for the best fruit of Blenheim Orange Melon, which were won by Mr. J. Anderson Rose, Wandsworth Common, and Mr. Waite.

NOTES ON PLANTS.

CLEMATIS SIR GARNET WOLSELEY.—As an early flowering variety this Clematis is one of the best. At the present time it covers a west wall about 15 feet high, half as much wide, and its

flowers are produced in profusion over the whole space. Annually it flowers in the same manner, thus rendering what otherwise might be a dull spot particularly showy. I find a mixture of loam, peat, and manure suits these plants, and copious supplies of liquid manure at the time when growth is being made adds much to their future flowering propensities. All this would be of little avail if pruning the shoots was not carried out in a manner agreeable to the section to which this variety belongs—viz., the *C. patens* spring-flowering type. The *C. Jackmanni* type, for instance, require close pruning, but in this instance a mere shortening of the points is all that is needed; but in our case the wall is much higher, therefore we do not prune at all. The points are damaged by strong winds, which answers the purpose of pruning.

SILVER HOLLIES.—At this season of the year not the least effective shrubs are Silver Hollies. When new growth is being made the young leaves assume a bronzy hue, which in contrast with the silver foliage of the older leaves is very striking either at a distance or for close inspection to those who admire the different tints the foliage of various trees and shrubs bear at a time when new growth is being made. A close annual pruning of Silver Hollies renders the effect named more striking.

FABIANA IMBRICATA.—A desirable plant to cultivate for the hardy Heath bed, although it grows strongly when the conditions are favourable—open position to the sun, sheltered from north and east winds. It delights in good fibrous peat, does not grow in a straggling loose manner, but preserves an upright compact growth. It never fails to flower profusely during June, and lasts a long time in good condition. Its free flowering character is thoroughly exemplified by some young plants which were raised from cuttings in a cold frame last September, and are now covered with flowers. A stock of plants is easily obtained in the above manner. As the plant has an upright habit of growth, to secure a bushy plant the leading shoots should be topped while in a young state the first season, the same treatment being adopted for the first two or three years. I lately saw a very fine specimen, which was planted out under a verandah with a glass roof facing south. Growth was freely made; it was covered with the largest pure white blossoms I have yet seen. A thorough ripening of the previous year's wood no doubt assisted the flowering.

GLADIOLUS COLVILLI.—The varieties of the above are useful plants to grow for early indoor supply of flowers. The snowy white variety, *The Bride*, is as choice a flower as it is possible to have at this time of the year. *Cardinalis*, when a little colouring is wanted to associate with the former, is one of the best. So simple in cultivation are these varieties that they ought to be more generally grown in private gardens. We succeed with them by placing three or four corms in a 48-sized pot, using sandy loam with some decayed manure added. About the middle of October this is done, placing the pots on a shelf in the greenhouse, which is kept cool. Scarcely any water is given for a time beyond keeping the soil moist until growth is well started, when water is freely supplied, alternating the supply with tepid liquid manure. Here the plants remain until they are in flower. For the decoration of rooms in the house they are equally as well suited as they are in a cut state for filling vases.

DOGWOOD.—The common Dogwood is most useful when planted under the shade of overhanging boughs of large forest trees, and there are few really good shrubs suitable for planting in such a position. It is now densely clothed with deep green foliage, surmounted by its white flowers looking quite cheerful. During the winter, when leafless, Dogwood makes a bright show, the bark of its branches having quite the colour to effect this—a warm reddish tinge. Indeed any plant that will flourish under the shade of trees, no matter how common, ought to be encouraged.

DEUTZIA GRACILIS IN THE SHRUBBERY.—In the South of England this *Deutzia* makes a good shrubby plant, remaining for many years in a comparatively dwarf state. It grows bushy and dense, never failing to form an abundance of flower buds, which sometimes are much injured by late spring frosts before they have time to develop. When in flower it is a showy plant. The flowers last a long time, the rain seeming not to injure them in the least. As the plant can be had at so low a price it does seem strange that more of it is not seen in the shrubberies even in the South of England. Perhaps its scarcity is owing to an imperfect knowledge of its adaptability for the open borders.

ALLIUM MOLY.—For planting in the mixed shrubbery where space between the shrubs and trees will not admit of tall-growing herbaceous plants, and which places require brightening, this *Allium* is excellent. It grows luxuriantly in almost any kind of soil; particularly is this so in strong soil approaching closely to clay. It throws up numerous flower spikes, which develop showy bright yellow umbel-shaped flowers. The disagreeable odour emitted from this plant when the leaves are disturbed is the most objectionable part in connection with this *Allium*.

VIBURNUM OPULUS.—I have never seen the Guelder Roses flowering so freely and so finely as they are doing this year, which is owing somewhat to the thoroughly ripened wood last season consequent on such a hot summer as that experienced. It thrives and flowers freely in stiff retentive soil, producing large heads of bloom, while the foliage is dense green. When in a small state three or four plants massed together in the mixed shrubbery are most effective, as well as useful for cutting where white flowers are in much request.

PHACELIA CAMPANULARIA.—This annual is in fine condition now, flowering so freely and early as it does. Its deep Gentian-like blue is at once attractive, and it is a pity that it does not last the whole season, when it might be made to do duty as a summer bedder. The best method is to sow the seeds in the spring where the plants are to remain in preference to sowing them under glass, as the roots are so fine and shyly produced that transplanting causes a check from which it takes a long time to recover, particularly if the weather be at all hot and dry, or even if too cold at the time of planting.

XIPHIDIUM VULGARE.—At the present time this is a showy plant for the herbaceous border, its bright purple flowers freely produced present an attractive appearance. No special preparation is needed to grow this Iris. Ordinary garden soil with some manure added is all that is required. The flowers are produced on long spikes, rendering it all the more valuable for cutting when required to mix with other flowers in vases. A stock of plants is readily obtained by dividing the roots where the plant grows strongly. A capital companion to the above is *Iris pallida*. Being a strong grower it throws up stout spikes which produce numbers of pale blue flowers when the soil in which it grows is moderately rich. This Iris is very showy for the mixed border.

CERCIS SILIQUASTRUM (The Judas Tree).—It is only in a few gardens that this tree is met with. Flowering early as it does in May before the foliage is expanded renders it the more remarkable. The peculiar manner in which its flowers spring from the main stem, quite close down to the ground in some instances, adds much to its odd appearance. It is very showy when bearing its bright purple flowers, and the leaves which appear afterwards assume a deep green tint. When planted in the mixed shrubbery, except in most favoured localities and positions, the annual growth is not rapid. A south wall suits it best.—E. M. S.

CROPS THAT PAY.

BRUSSELS SPROUTS.

DURING a conversation with a friend a short time ago I tried to induce him to grow Brussels Sprouts as well as early Potatoes on the acre of land that surrounds his house, planting the Brussels Sprouts 3 feet apart, and the Potatoes between the rows 18 inches from plant to plant. All my efforts were fruitless, for he contended the early Potatoes were his best paying crop, and Sprouts did not pay to grow. "Believe me," he said, "they take more out of the ground than they are worth. I have decided to grow only what I want for my own eating." Turning to a small plot of ground on which were scattered small Turnips, evidently to be dug in, my friend remarked, "I sowed Turnips after the Potatoes were dug, and they have paid me ten times better than Brussels Sprouts would have done. Everybody's Turnips failed but mine; I could have sold as many more, and I am sorry I did not sow the seed I have in the house. Why," he went on, never giving me the chance to speak, "I know the Potatoes to a row where Sprouts have been grown; you would be surprised if I showed you the difference." He forgot I was a Brussels Sprouts grower, and he wound up by saying, "I will have no more of them, not more than a row or so." It was then my turn. "Are these the only reasons you have for not growing them?" "No," he replied, "you can get nothing for them when they are grown. I can make more out of them by selling the plants at 2d. a score." This certainly seemed conclusive, but I was, and am, still firmly convinced that they are the most profitable crop that can be grown. Land planted exclusively with them will yield a better return than Potatoes will in most seasons. They certainly take a good deal more out of the soil, but if well and properly managed they pay for this and then leave a balance in their favour. Such, however, has been my experience, and if this was not the case I should not have nearly trebled the amount of land under this crop. The reason they do not pay my friend is because he is at too great a distance from a good market. Unfortunately for him, produce for miles round is rushed into moderate sized towns, and the consequence is the market is "glutted," and sometimes the returns do not cover the carriage. After all, my friend had grown a few last year and realised 8d. a stone for them, out of which he had to pay 2d. for carriage and commission, so that his returns were 6d. a stone clear.

Well might he say they did not pay for growing, and when I knew this I could thoroughly understand his clinging to the early Potato crop. Brussels Sprouts certainly would not be a paying crop at 6d. a stone, but for double that amount they would pay well.

Small growers are placed at great disadvantages, and if they attempted to send their produce to good markets at a distance it is very questionable if they would get even 6d. a stone returned, the whole would be swallowed up between commission, portage, and railway rates. Not only so, but small odd lots are often sold for considerably less than the market value. I have known many instances of this, and those who send a regular supply of produce in moderate quantities fare the best, but those who can take their own produce and sell it have the best of the bargain. This would, and does not pay, those even in the neighbourhood of good markets unless they can take sufficient to more than compensate them for the time taken up in going to market. Fruit and vegetable growers residing some distance from a market would do well to unite in sending their produce, which would allow of their sending it away to markets where vegetables are in demand, with the result that all would profit by so doing. Not only should they unite for this purpose, but if they formed associations they might bring ample influence to bear upon the officials of the railway company that runs through their district to carry garden produce at reduced rates. Not only is this a question for the grower, but the consumer also should move as well in bringing this matter prominently forward. In the end the railway companies would gain largely by so doing, the consumer would benefit enormously, and the grower would be fairly remunerated for his labour. Landowners would also gain, for land that is now idle would soon be brought under cultivation and would yield a very fair return. Such a step might, and would, be the means of raising a cry for a reduction of rents for land in the neighbourhood of towns, but good land near good markets will always be worth sufficient rent per acre to make it a good investment, even if considerably less is paid for it than is the case at present.

I have said that the present state of things affects the consumer of vegetables enormously, and it may be well to examine the grounds for such a supposition. If we consider for a moment, my friends, Brussels Sprouts, last year, practically given away, and the lowest price they realised last season in good markets in the provinces—namely, 2s. a stone clear. The supply at this price was not equal to the demand, and higher prices were obtained, but it is as well to give the lowest. Now these were bought by greengrocers and sold by them, therefore readers can form their own idea what the consumer had to pay for them. Some might, and doubtless would, lose considerably by altered circumstances on the lines suggested, but I think it only right that the consumer should be able to obtain produce without having to pay exorbitant prices, as is often the case at present.

To return to our subject. Brussels Sprouts if well grown, and the strain good, are a certain crop. They are not half so liable to club as Broccoli, and are certain to brave without injury the severest of winters. When raised early they can be cleared from the ground in time for any other crop. The latest supplies can be cleared in time for a crop of French Beans; in fact before it is wise to sow the main crop of these, two rows of Cos Lettuces may be planted, and the Beans sown between them after the middle of April. The latest Sprouts are best obtained from plants sown outside in a sheltered position the last week of March or during the first days of the following month. If plants from this sowing are planted out directly they are ready on well-worked and liberally manured land, they will become strong and prove very remunerative, especially if they are assisted with liquid manure after the Potatoes are dug. But if planting is delayed until dry weather in June or later, they will be a long time before they make progress; in fact half the season will be gone before they are thoroughly established and growing freely, therefore the return is scarcely half what it otherwise would be. When late planting is practised the plants may be placed 15 inches instead of 18 inches apart in the row. Brussels Sprouts without doubt do best and pay best when the plants are raised early. They attain a greater length, and consequently yield at least a third more sprouts. This esteemed vegetable is in demand directly Peas and French Beans fail. The market supply of the former is generally of short duration in comparison with that obtained in private gardens by successional sowings. Beans are then demanded and followed by the Sprouts. Seed should not, however, be sown too early, the 1st of March being soon enough. When sown early in February there is some risk of failure from the plants commencing to flower during the early part of June, especially if dry weather sets in during May. Another cause of flowering or "bolting" is pricking the plants out of the seed boxes into other boxes or frames in light rich compost that induces a quick soft growth. Plants raised by such means are

not to be relied upon. They may be as large again as plants raised on hardier principles by planting time, but the smaller sturdier plants in the end will surpass them. If the seed is sown in boxes the plants should be grown hardy until they are large enough for pricking into frames placed on the ordinary soil of the garden. Our plan is to sow in a frame and then draw out the largest plants and transplant them when large enough 2 inches apart in a sheltered position where they can have slight protection at first if cold severe weather follows transplanting.

Planting in the position in which they are to grow is commenced as the Potatoes receive their final earthing. The Potatoes are planted in shallow drills drawn out with a hoe made for the purpose, and then earthed-up directly they show, and the soil is well worked to destroy small weeds. If the weather is dry water is poured between the rows and the Sprouts placed in. A little water to start them prior to planting is all that is needed, for sturdy plants are soon established, and at this time of year are growing vigorously.

Small Sprouts are not the most profitable for the market, they take too much gathering and weigh too light. The Aigburth is one of the best. When gathering commences it is unwise to spoil the sample by mixing the loose Sprouts with those that are firm and compact. In the end it is the most satisfactory to gather these and sell them by themselves. Such "dodges" are too frequently practised, and only entail disappointment and loss on the buyer, while the grower adds to his reputation to such an extent that his produce is passed by for that of men who can be fully relied upon.—MARKETER.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

UNDOUBTEDLY this, in our opinion, is one of the best, and best managed of charitable institutions in this country. It enjoys the patronage of the Queen and Prince of Wales, the Duke of Westminster is its President, and its Vice-Presidents include noblemen and gentlemen of distinction in the horticultural world, or in sympathy with the objects of the charity. Its stability is certified by the fact of upwards of £21,000 being invested in Consols, and is increasing yearly. It affords support to 126 pensioners; gardeners whose term of labour is over, or widows of gardeners, who are thus provided with sustenance in their old age. The sum distributed in pensions last year amounted to £2124 10s., apart from the special distribution of £655, contributed mainly by gardeners commemorative of the fiftieth year of Her Majesty's reign, and which enabled £5 extra to be granted to each pensioner and to each unsuccessful candidate at the last election. Thus an enormous amount of good is being done by this Institution, but as remarked by the Chairman in his speech at the dinner referred to below, a great number of persons who derive a large amount of pleasure from their gardens are not yet enrolled as subscribers to the fund. Mr. Veitch also pointed out the sad fact that at the last election no less than fifteen candidates had to be excluded through the amount at disposal being exhausted.

In the election of persons to participate in the benefits of the Institution preference is given to subscribers for fifteen years, subject, however, to the rules bearing on an investigation of the claims of applicants. There are about 1100 subscribers of a guinea, but by no means all of them are gardeners, several nurserymen, seedsmen, and others contributing not for their own benefit, so that it would appear there are many who might at some time be glad to share in the advantages of the Institution that do not yet accord it support. Hundreds would willingly do so no doubt if they were able, but a large margin must remain of gardeners who could spare a guinea a year who have not yet seen their way to do so; but several have collected 10 guineas, and in this way become life subscribers, and who at some time if necessity should arise may have preference in an election. The Gardeners' Royal Benevolent Institution deserves extended support both from the affluent who derive pleasure and benefit from gardens and from those who cultivate them, and if the latter should be so fortunate as not to need its assistance their satisfaction should be the greater in contributing to the support in the time of need of their less favoured fellow workers.

The anniversary festivals of the Institution rank among the events of the year in the horticultural world. The first of these gatherings was held in 1844, at which Mr. John Noble presided, and the last held at the "Albion," Aldersgate Street, London on the 4th inst., when a distinguished statesman and orator was expected to occupy the position of chairman. Illness prevented Mr. Chamberlain's attendance, and the disappointment was deeply felt. The President of the Royal Horticultural Society—Sir Trevor Lawrence, Bart. M.P.—kindly stepped into the breach and acquitted himself well. The room and approaches were beautifully decorated

with plants, and the tables were befittingly laden with flowers and fruit for the occasion.

THE DINNER.

Grace having been sung, the Chairman announced that he had received a letter and a subsequent telegram from Mr. Chamberlain, but he would refer to them later on. The Chairman next proposed "The Queen," and alluded in touching terms to the great sorrow Her Majesty had lately experienced. On the other hand, they all hoped that Her Majesty's grandson had before him a long, happy, prosperous, and useful career.

The Chairman then proposed the toast of "The Prince and Princess of Wales and the rest of the Royal Family," and remarked that, not only was His Royal Highness patron of the Institution, as was his illustrious father, but the Duke of Connaught not very long ago took the chair at one of their dinners. It was their hope that some member of the Royal Family might again occupy a similar position.

Mr. J. R. Bourne next proposed the "Navy, Army, and Reserve Forces," each service being responded to severally by Admiral Field, M.P., Major Bolton, and Major Gole.

The Chairman upon rising to propose the toast of the evening, "Success and Prosperity to the Gardeners' Royal Benevolent Institution," was received with loud cheers. He said he need hardly say what keen sense of disappointment he felt when he heard that the Right Hon. Joseph Chamberlain had been prevented by illness from being in the chair that evening. He had had the pleasure of listening to many speeches on many subjects from that gentleman, and he (the Chairman) was bound to say that whatever the occasion, and whatever the subject, Mr. Chamberlain had been always able to bring to the subject some new illustration, some new method of interesting his hearers in what he was speaking about, and something which recommended what he said to the judgment of those whom he was addressing. He had in his hand a letter from Mr. Chamberlain, and also a telegram, in which he said, "Thanks for kind expressions, I shall be happy to come some other night." He was sorry that the Committee of Management had not been able to find somebody who would have been more able to bring a little freshness to the toast. The objects of the Institution were well known to everyone, as well as its claims, but in looking through the list of subscribers, he was sorry to say that he found the names of a large number of friends of his own absent, who derived a large amount of pleasure from their gardens, and felt sure it had not been brought to their notice that they ought to subscribe to the Institution. The Institution did not do anything that was at all extravagant. What did it do? It simply gave to the men who were pensioners £20 a year, and to the women £16; surely it would be impossible to do less than that. It had got on its lists a very considerable number of gardeners, and he was glad to see that it was enabled to add to the comforts of their old age, and a considerable number of them. The average age of the pensioners he found was seventy-four, and their oldest pensioner was 100 years of age; therefore, gardening did not appear to be an unhealthy occupation. The number of applications was larger than the charity was able to help. The total expenditure was only £2250, and when he recollected the enormous interest which the people of this country took in gardening, he must say it was a reflection on the wealthier people of the country that they did not support the Institution more largely. The Institution had made it a rule to help those who helped themselves, and that preference was given to those who had been on the books of the Society fifteen clear years before any help was given to others. A lady had once asked him whether he thought an Orchid was more beautiful than a Rose. He thought the proper course to take in such a case was to show them the door at once, because he did not think they could take any interest in any form of gardening. It was quite possible to take an interest in a Rose and admire an Orchid at the same time. He had been successful in gaining a prize at a show for twelve Roses, and he had also gained one of the National Rose Society's gold medals, the only fault he had to find with which was it was so small he could hardly see it. He ventured to think that they ought to work the field of gardening, and the interest the people took in their gardens, more largely than was done, in the interests of the Society. Possibly at no period of the history of the Society was so much money spent upon gardening as now. Therefore he thought the Society should be brought under the notice of proprietors of gardens who spent large sums in getting pleasure out of their gardens. Gardeners often found themselves in a position of having very little for their declining years, and he could not believe that people who got enjoyment out of their gardens would not be prepared to provide for the maintenance of that admirable Institution. (Cheers.) He did not think that he need detain them any further, only to wish that his friend Mr. Chamberlain had been present. So far as he was personally concerned, he felt he should occupy the position very imperfectly. (No, no.) He coupled with the toast the names of Mr. John Lee, who had only missed one dinner out of forty-five, and Mr. H. J. Veitch.

Mr. John Lee, in response, thanked the company for the enthusiastic manner in which they had received his name, and went on to say that they owed a great debt of gratitude to the Chairman for having at a moment's notice consented to preside that evening, and to those gentlemen present for the generous support they had given to the Institution, as it was through their generosity that it had been raised to a high pitch of excellence, and had been placed on a solid basis, which he, and he knew they all, hoped it would maintain for many years to come.

Mr. Harry J. Veitch also responded, and having returned thanks for

the hearty reception accorded him, alluded, as Treasurer, to the financial position of the Institution, which, he said, was managed as carefully as it was possible to manage any institution. He would again like to remind them that the interest on the money subscribed all went in benefiting their pensioners. They had no large buildings to keep up, and no expensive staff to maintain, but they were obliged to have a Secretary, whom they paid as little as possible. With that one exception, the whole of their money was devoted to the purpose for which it was given. They had 126 pensioners, but at present they had only one election a year; and at the last election they were obliged to omit fifteen unfortunate candidates for want of funds. That was a sad thing for either men or women, but one case was particularly sad, as in that instance the applicant lost by only nine votes after having secured 700. The present bad times affected gardeners even more than most other servants, as they were the first to be discharged in times of scarcity. He knew of cases where gardeners had been out of employment for three and four years, and they were compelled to spend what little savings they had put by for old age. This Society tried to meet those cases, and he was bound to say they made the funds at their disposal go as far as they possibly could. (Hear, hear.) Unfortunately for the Society, they had lost 50 guineas a year by the conversion of the three per cent. Consols. That was not, however, the place for speaking politics, but he simply wished to allude to the fact. In conclusion, he said if they could only see the tears of joy in the eyes of recipients they would not fail to continue their liberal support to the Institution.

Dr. Masters proposed the health of the Chairman, who briefly responded, and then the Secretary, Mr. Cutler, made the gratifying announcement that the night's donations amounted to 1000 guineas. Their Chairman had given £10 10s., and Mr. Chamberlain's list amounted to £435, while quite £200 had been subscribed by gardeners in small sums. The Chairman then proposed the health of "our old friend, Mr. Cutler," who responded amid great applause. Mr. Tidswell then proposed "The Houses of Parliament," which was responded to by Mr. H. L. W. Lawson, M.P. The last toast was that of "The Honorary Officers," which was responded to by Mr. B. S. Williams.

There was a very large attendance, and the proceedings were rendered the more enjoyable by the admirable singing of the talented vocalists, under the direction of Miss Mary Belyal, the accomplished daughter of the Secretary of the Institution.

EVENTS OF THE WEEK.—Besides the Rose shows announced on another page Exhibitions will be held at Winchester and Chiswick to-day (Thursday), the latter being likely to attract much interest owing to the competition for the challenge cup in the group classes. The principal event of the week will, however, be the Gardeners' Orphan Fund annual meeting and dinner at the "Cannon Street Hotel" on Friday, the 13th inst. The meeting takes place at 2 P.M., the ballot closing at 4 P.M., to be followed by the dinner at 5 P.M.

— WE are pleased to observe, in the *Gardeners' Chronicle*, that DR. MAXWELL T. MASTERS has been presented with the insignia of Chevalier of the Order of Leopold by H.M. the King of the Belgians, the decoration, we presume, which attracted attention at the dinner of the Gardeners' Royal Benevolent Institution last week. Dr. Masters was Vice-President of the Jury of the International Exhibition of Ghent in April of the present year.

— THE WEATHER.—Our Perthshire correspondent writes:—"We have as yet had no genuine summer weather. Previous to last week, which had been dull and showery, there was a good deal of bright sunshine, but easterly winds prevailed, with low temperature at night. On the morning of the 1st inst. Potatoes in this district were blackened by frost. Shortly before in many places Dahlias and other plants had suffered. Turnips have had in many parts of the country to be resown. Hay promises well, and cutting has begun. There is every prospect of a late harvest." There has been a continuance of rain in the south, broken only by fine summer-like weather on Sunday and subsequent days.

— A WAKEFIELD correspondent says:—"The weather is very unsettled and cold for July, prevailing winds N. and N.E., the thermometer at 7 P.M. on Tuesday standing at 47°. As this is a fair sample of what our experience has been for some days it makes everything very late."

— **THE GARDENERS' ORPHAN FUND.**—A reminder may be given that the first anniversary dinner, also election of children to the benefits of this Fund, will be held at the "Cannon Street Hotel," London, on Friday in this week, the time of the dinner being five o'clock. A good assemblage of nurserymen, gardeners, and others interested in the charity is expected, and persons who have not obtained tickets can, we believe, be supplied at the Hotel on Friday by Mr. Barron, the Hon. Secretary. Sir Julian Goldsmid, Bart., M.P., will preside on the occasion. It is hoped that all who can conveniently attend the dinner will do so in the interests of this young and excellent organisation. The paragraph in last week's issue in reference to the election was sent to us inadvertently, without the authority of the Committee. The simple rule is that every 5s. subscription gives one vote.

— **A CONFERENCE OF FRUIT GROWERS.**—Arrangements have been in progress since May last for holding a conference of fruit growers in the Crystal Palace, Sydenham, on the occasion of the Fruit Show, September 7th and 8th next, and to carry out the scheme a large Committee has been formed, including about sixty of the leading nurserymen, gardeners, and market growers. A meeting of the Executive Committee was held in the Crystal Palace on Saturday the 7th inst., T. Francis Rivers, Esq., in the chair, and the general programme of the conference was decided upon. It is intended to deal exclusively with fruit culture from a profitable point of view, with special reference to Apples, Pears, and Plums, packing, carriage, and marketing, preserving fruit by drying, &c., and the dietetic value of food. The latter portion will probably be considered at the second day's meeting.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The quarterly meeting of this Society was held at the "Caledonian Hotel," Robert Street, Adelphi Terrace, Strand, on Monday evening last, Mr. George Wheeler in the chair. Two new members were elected, making an addition of thirty-nine this year. The membership now stands at 291, including honorary members. The Committee are very pleased to state that the Society is in a healthy condition, no one being on the sick list at the present time. A copy of the rules will be sent to any address for six stamps, on application to the Secretary, Mr. W. Collins, 5, Martinhoe Terrace, Martindale Road, Balham, S.W.

— **WE regret to learn that the REV. WALTER SNEYD** of Keele Hall, Newcastle, Staffs, died suddenly on Monday, July 2nd, having only been ailing a few days. Keele Hall Gardens are well known in the horticultural world, having been for some years under the charge of Mr. Wallis.

— **LOUTH ROSE SHOW.**—We learn that Mr. A. James, of Rams-gate House, the Hon. Secretary of this undertaking, is sparing no efforts to make this Show a decided success. The event is fixed to take place at the Town Hall, Louth, on Wednesday, 25th inst., and in addition to the display of Roses there will be a musical promenade and a miscellaneous concert. Over £25 is offered in thirty-nine prizes. There are thirteen classes—namely, five open to all comers, three to the county of Lincoln, two to amateurs within a fifteen mile radius of Louth, two for lady competitors, and one for cottagers only. Intending exhibitors should obtain a schedule from the Secretary. The entries close on Monday, the 23rd July.

— **AT the WIMBLEDON SHOW** last week, for which we have not space for a detailed report, plants of various kinds were admirably staged by Messrs. Alderman, Bentley, Chandler, Waite, Law, Ware, Methven, Hunt, Cresswell, Thornton, Newell, and Cole, good gardeners in the district, to whom prizes were awarded. Messrs. J. Laing & Son staged a splendid group of Begonias and Orchids. Vegetables of great excellence were staged by the skilful cultivator of them, Mr. J. Waite, of Esher, who secured the chief prizes offered both by the Society and Messrs. Sutton & Sons. Other prizewinners in the classes were Messrs. Cole, Bentley, Methven, Newell, Chandler, Law, Parsons, and Goodyear. The Show was admirably managed by Dr. George Walker and Mr. J. Lyne, and both they and the exhibitors deserved better weather—at least that was the opinion of the Judges, and from their decision there was no appeal after five o'clock, and this involved the payment of 5s. for the luxury, to be returned if sustained, to be retained if frivolous—not at all a bad arrangement. It is a pity a more complete report cannot be given of the Show, but it is useless struggling against the claims of the Roses at this time of the year. Fruit was very good, notably in the first prize collection from Mr. C. Gibson, who was first also with Grosse Mignonne

Peaches and a superior Melon. Mr. Griffin had the best Grapes, and Mr. Alderman the best Strawberries, a fine dish of Unser Fritz.

— **GARDEN APPOINTMENT.**—Mr. William Webber, late foreman at Lowther Castle, Penrith, has been appointed head gardener to Mrs. Seymour, Norton Hall, Daventry, Northamptonshire.

— **DICKSONS, LIMITED, CHESTER.**—The above is now the title of the combined firms of Messrs. James & F. Dickson, the amalgamation dating from July 2nd. The firms have traded separately for about thirty-four years, but were formerly united. Mr. George Dickson is Managing Director and Chairman of the business, and Mr. E. J. Baillie the deputy Chairman. Messrs. W. A. Dickson, James Dickson, and John S. Dickson are also Directors of this great (family) Company of nursery and seedsmen.

— **MESSRS. OAKSHOTT & MILLARD** in requesting an opinion of their new **EARLY EIGHT-WEEKS ONION** state:—"The seed from which these specimens were grown was sown exactly two months since, and they are two weeks earlier than Queen sown the same day." The bulbs are white and well formed, the largest $3\frac{1}{2}$ inches in circumference, and the necks thin. The examples represent very quick growth. It belongs to the Silver-skinned section, the varieties of which are worth trying as winter Onions, sowing in August for early spring use.

— **SINCE the famous INTERNATIONAL HORTICULTURAL EXHIBITION, HELD AT COLOGNE** in 1862, none has been projected on so large a scale, or promises to be of so important a character as the one to be opened there early in the ensuing month. Arrangements are proceeding rapidly under the direction of the Executive, presided over by the Consul-General for Austria-Hungary, Baron Oppenheim. They have appointed as Commissioner for the British section Mr. T. J. Wesley Bennett, F.R.S.L., F.C.A., of 61½, Fore Street, Moorgate, London, E.C., to whom all communications should be addressed with reference to that section.

— **CROYDON SHOW.**—We are informed that the vegetables and salads shown by Wm. Jupp, gardener to Cuthbert Johnson, Esq., Wal-drons, Croydon, at the Croydon Horticultural Society's Show, were given to the Croydon General Hospital. Messrs. J. Laing & Sons remind us that "no mention" was made of their group of Begonias, Orchids, &c., at this Show. It was a Wednesday's Show—the day on which we go to press, and only the leading Rose classes were reported. Even the prizewinners in other sections could not be mentioned, and note was not taken of them. Journalists cannot act independently of time and space, but do the best they can under the circumstances.

— **ESCALLONIA MACRANTHA.**—Planted so that it is trained up a wall in almost any situation *Escallonia macrantha* is very handsome, or as a bush in the shrubbery it does equally well. For covering large rockeries it is capital. Its glossy deep green leaves form such a delightful contrast to its rich pink flowers, which are freely produced during the greater part of the summer if the old flower stems are cut off directly the first ones have faded, as new growth commences at once, which will again blossom. A fairly rich soil, to which some peat is added, suits this plant to perfection. Copious supplies of water during the summer when the position is a dry one benefits it greatly.—M.

— **TWENTY-SEVEN** members of the **EASTBOURNE HORTICULTURAL SOCIETY**, accompanied by their President, the Mayor of that town, F. Bolton, Esq., made a special journey to Messrs. Cannell and Sons' Home of Flowers, Swanley, on Wednesday, the 4th inst. They were escorted through the several glass houses by Mr. H. Cannell, sen. Begonias, Fuchsias, Pelargoniums, Chrysanthemums, claiming much admiration, also other departments. A journey was then made to the Strawberry picking district, 50 acres in one piece causing astonishment. The large establishment of Mr. P. Ladds was also visited, where Grapes, Tomatoes, and Roses, together with the gigantic glass houses, astonished the whole party. At 6 P.M. the members started on their return journey, evidently delighted with the visit.

— **FROM Mr. J. Murphy** comes this request for information:—"It may occasionally be desirable to chronicle failure—if only for variety—as well as success. For several years I have tried various methods of inducing *IRIS SUSIANA* to flower, and so far without success. I have planted it in the herbaceous border with some manure and leaf mould, and transferred it from that to a raised bed with a southern aspect, sub-

stituting a fractional part of peat and plenty of drainage. The plants are healthy, but will not bloom this year. If I remember correctly you published an instructive, as well as humorous, article on this subject from Mr. F. W. Burbidge, Trinity College Botanic Gardens, Dublin, last year, describing how an untutored 'gardener,' and I believe groom, flowered this Iris to perfection. I cannot place my hand on the number, but perhaps some correspondent would tell how success can be won, and the matter would interest others as well." [The note in question appeared on page 150, February 23rd, 1888.]

— "W. J. M." writes:—"Abundance of bloom was produced on the majority of both trained and standard APPLE TREES, but the crops are not generally good. The caterpillars have greatly disfigured many trees, both foliage and fruit being much injured. Various small birds have done much towards clearing the trees of caterpillars, and in the case of all dwarf trees it has been found that the time expended in crushing caterpillars has been well spent. There are very heavy crops set on sheltered trees, and in the case of Lord Suffield, Hawthornden, Duchess of Oldenburgh, Tower of Glamis, King of the Pippins, Cox's Orange Pippin, Braddick's Nonpareil, Margil, and a few others thinning is necessary. The clusters being very thick one well formed fruit only should be left on each, the rest being cut away. They will well repay for this rather tedious labour, fine well formed fruit being of more value than four times the number of inferior samples."

— AUTUMN-SOWN ONIONS.—"D., Birmingham," sends [the following note:—"Last year I sowed some White Spanish Onion seed in June, but the season was so hot and dry that many of them were even too small for pickling, so they were put into a box and forgotten, until they came under notice in April last. The bulbs were very small, none larger than a small Hazel nut, and were very much dried, but I put them into common garden soil scarcely manured at all just to see if they would grow. Every one grew, and I have bulbs 1½ inch in diameter. Some of your readers may have had experience in growing the ordinary summer sorts in this way (I do not mean the Tripolis), but it seems to be easy to grow larger roots than usual of the Spanish section especially, if the plan I have described were adopted, only bearing in mind that only very small bulbs could be used with safety as not likely to run to seed. In good soil and with a little attention I do not see why very large roots may not be grown."

— NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY.—The usual monthly meeting and Show in connection with the above Society was held in the Arboretum Rooms recently, when there was a large attendance of members and friends. There was on view a large and varied collection of plants, flowers, and fruit, for which money prizes were awarded. Amongst the principal exhibitors were Mr. C. J. Cox, of Basford, whose gardener, Mr. Meadows, put together a well-arranged group of plants, conspicuous amongst which were many finely coloured Crotons, Palms, Caladiums, &c. The principal money prize was awarded to this group. W. H. Farmer, Esq., of Alexandra Park (gardener, Mr. A. Hanborough) followed closely with a well-arranged collection of plants. The third in order of merit for groups fell to Mr. James Booth, of Mapperley Road (gardener, Mr. Ralphs), and contained many small but well-grown plants. Roses formed another leading feature. Mr. Foulgham, Hunger Hill, obtained first honours; Mr. T. B. Hallam, St. Ann's Well Road, closely following with a very fine lot. Mr. E. Massey (gardener, Mr. Bateman) was a good third. Lieutenant-Colonel Seely, Sherwood Lodge, sent, through his gardener, Mr. Swanwick, a fine collection of seedling Gloxinias and two good Melons and Cucumbers. Hanging baskets of flowering plants were contributed by Mr. Houley, Nottingham; and Mr. J. W. Lewis, The Park, sent some very good specimens of cut stove and greenhouse flowers. Messrs. J. R. Pearson & Sons, Chilwell, had fine examples of the celebrated Cucumber Long Gun, and Mr. Johnson, of St. Ann's Road, exhibited a small collection of vegetables.

— ROYAL BOTANIC SOCIETY'S EVENING FETE.—The following is the list of prizewinners at the successful fête held in the Botanic Gardens, Regent's Park, on July 4th:—Division 1, natural flowers, fruit, &c.—Floral decorations for a dinner table: First, Mr. W. L. Buster; second, Messrs. W. G. & P. Phillips; third, Mr. J. R. Chard. Floral decorations for table dressed for dessert.—First, Messrs. Hooper and Co.; second, Messrs. W. P. & G. Phillips; third, Mrs. E. Spurling. Foliage and flowers, for a sideboard.—First, Mr. W. Gardener; second,

Mrs. Henderson; third, Mrs. E. Bengafield. Small group of growing plants for table.—First, Miss A. Gardiner; second, Mr. J. Prewett; third, Mr. J. W. Chard. Groups of plants for a recess, alcove, or fireplace.—First, Mr. J. R. Chard; second, Mr. R. Scott; third, Miss A. M. Williams. Standing basket, vase, &c., with plants.—First, Messrs. Henry & Co.; second, Mr. C. Handley; third, Miss A. M. Williams. Hanging basket, with growing plants.—First, Mr. R. Scott; second, Mr. J. R. Chard; third, Messrs. Hooper & Co. Window box of plants.—Third, Mr. C. Handley. Bridal bouquet.—First, Mr. W. Gordon; second, Mr. J. R. Chard; third, Mr. J. Prewett. Ballroom bouquet.—First, Mr. W. Gordon; second, Mr. A. F. Youens; third, Miss Gertrude Paget. Group of flowers, &c., stalks in water.—First, Mr. A. F. Youens; second, Mr. H. O. Garford; third, Mr. F. Perkins. Flowers which expand only at night.—No exhibits. Arrangements of flowers, leaves, &c., for personal adornment.—Small silver medal, Messrs. Perkins & Son; large bronze medal, Mrs. Gray; bronze medal, Miss Alice Gardiner. Miscellaneous.—Large silver medal to Messrs. W. Paul & Son and Messrs. W. P. & G. Phillips; silver medal to Messrs. Hugh Low & Co., Mr. C. Turner, and M. Smont; small silver medal to Messrs. Barr & Sons. Division 2, works of Art:—Paintings, drawings, and carvings.—Small silver medals to Miss C. E. Lohr and Mr. W. Aumonier; large bronze medals to Miss B. Maguire, Mrs. Southam, and Miss A. Bell; bronze medal to Miss Emily Cook; small bronze medal to Mr. A. G. Hawes, Miss H. M. Green, Miss C. L. Barton, Mr. Youens, and Miss L. Aumonier. Artificial flowers.—For personal adornment, small silver medal to Messrs. J. Shoolbred & Co.; for table decoration, bronze medal to Messrs. J. Shoolbred & Co.; for a model of Taraxacum officinale (Dandelion), certificate of merit to Messrs. J. Shoolbred and Co. Some remarks on the more important of these classes will be found on page 17. We are informed that Mr. J. R. Chard of Stoke Newington had the honour of presenting one of his bouquets to the Duke of Teck during the evening.

ROYAL HORTICULTURAL SOCIETY.

JULY 11TH.

THE Drill Hall at James Street, Westminster, was filled at the meeting on Tuesday with groups of plants and flowers of a varied character, Roses, Delphiniums, Gaillardias, Tuberous Begonias, and hardy plants forming the specialties.

FRUIT COMMITTEE.—In consequence of the meeting of the Committee at Chiswick on Monday only a few members attended on the present occasion. Those present were H. J. Veitch, Esq., in the chair, and R. D. Blackmore, J. Wright, J. Roberts, P. Crowley, and J. Willard. Messrs. W. Lovell & Son, Driffield, sent dishes of Vicomtesse Hericart de Thury and La Grosse Sucrée Strawberries for comparing their flavours; the first-named was considered the better. These, with King of the Earlies, it was stated, are the only varieties yet ripe in Yorkshire. A vote of thanks was accorded. Mr. W. Palmer, The Gardens, Thames Ditton House, sent his new Melon, Thames Ditton Hero, a fine-looking fruit, and of very good quality; also a small crimson Tomato, early, and of good quality, but neither of these was considered to be in the high condition necessary for receiving certificates.

Messrs. James Veitch & Sons sent an interesting collection of Peas in twenty-two varieties. The plants had been pulled up and were suspended in bunches, so that their heights and productiveness could be seen; a card was also attached to each variety showing the dates when the Peas were ready for gathering. Veitch's Extra Early, Dr. Hogg, and Emerald Gem were ready June 27th; William the First and Chelsea Gem, ready June 28th; American Wonder, Little Gem, William Hurst, and Kentish Invicta, ready June 29th; Laxton's Alpha, June 30th; Dickson's First and Best, July 1st; Blue Beauty, July 4th; Day's Early Sunrise, July 6th; The Duchess, Essex Rival, Auvergne, Telephone and Telegraph, July 7th; Advancer and Early Paragon, July 9th. A cultural commendation and vote of thanks were awarded, and the Committee considered Chelsea Gem very meritorious as a dwarf variety, height about 18 inches, and Dr. Hogg noteworthy for its earliness and good quality, height about 3 feet. A basket of the very early and useful Early Erfurt Cauliflower was sent from the Society's Garden at Chiswick.

On the preceding day a meeting was held in the Council Room at Chiswick, at which there were present—T. Francis Rivers, Esq., in the chair, and Messrs. Phillip Crowley, John Lee, J. Wright, J. Burnett, J. Willard, Charles Howe, J. Smith, J. Cheal, T. J. Saltmarsh, and W. Warren.

CABBAGES.—The varieties under trial were first examined, with the result that two of them were certificated; one a new, the other a well proved early sort, and the fact that it wears so well renders it the more worthy of the distinction. This is *Ellam's Early* (Veitch) the dwarfest, most compact, and with one exception the earliest in the collection. The other variety honoured is not inappropriately named *Express* (Vilmorin). It is a selection from the Early Etampes, a serviceable and excellent variety. Express is a dwarf grower, forming

hearts as early as Ellam's, but of twice or thrice the size, and is distinct in character from all others on trial. A few others that met the approval of the Committee were Myatt's Early Market (Watkins & Simpson), a true stock of what appears to be a hardy variety, for the rows were full and the plants uniform. The hearts are above medium size, firm, and well formed. It is fairly early, and a good serviceable Cabbage. Early Rainham, both from Messrs. Hurst & Bunyard, is somewhat similar in character, and a good market variety. Bailey's Early (Veitch) was approved by the Committee as a good second early garden Cabbage for succeeding such as Ellam's. It is below medium size, with conical hearts fresh and tender in appearance; of the same type and good, though perhaps a trifle larger and earlier, are Heartwell and Cocoa Nut. A full report of the trial will presumably be prepared in due course.

STRAWBERRIES.—These, of which there is very large collection, were next inspected. The rains have injured the fruits and impaired the flavour somewhat, yet some varieties were fine and of good quality. Certificates were granted to *King of the Earlies* and *Noble*, the former having medium sized fruits of rich flavour, the latter early and handsome, but not superior in quality. Certificates were also adjudged to two other varieties—one of them, *Lucas*, being an old favourite with many cultivators who know its worth; the other, not very new but much less known, *Countess*. Both these are good growers and bearers, the fruit of the former very large, mostly round, dark in colour and good in flavour; those of the latter (*Countess*) also large, but lighter in colour and mostly wedge or cockcomb shaped, and of superior quality.

Dr. Morère is a round, large, well flavoured Strawberry, but the plants not very vigorous. *Duchess of Edinburgh* good in size and flavour, but plants weak. *Souvenir de Kieff*, a free grower and bearer of good fruit both in size and quality. *Sir Harry* is the best of the "good old Keens' Seedling" type. For producing very large fruits for exhibition *Waterloo* and *James Veitch* are pre-eminent, the former very dark in colour, but plants weak, those of the latter being more vigorous and productive. In addition to the varieties named, *Vicomtesse Hericart de Thury*, *Sir Joseph Paxton*, President, and *Sir Charles Napier* hold their positions for general usefulness.

EARLY PEAS.—Several varieties of Peas are on trial, but the majority are not yet ready for use. Among the white round-seeded varieties it is a neck-and-neck race between *Carter's Lightning* and *Veitch's Selected Early*, the former being perhaps slightly taller, and both productive. Running these closely in earliness are the blue-seeded *Horsford's Free-trade* and *Canary Bird*, which are apparently good stocks of *Invicta*. *William I.* and *Dr. Hogg* are in practically at the same time as the two preceding, and are larger, also probably better in quality; the last named being especially sweet, and, obtained true, is one of the best early Peas in general cultivation. We have now to note a distinct step in advance in *Mr. Laxton's new Pea*, *Gradus*, which is not yet in general cultivation. This is ready with *William I.* but has pods and peas like those of *Telegraph*; indeed, *Dwarf Early Telegraph* is a good popular designation. It is a white wrinkled Marrow, growing 3 feet high. *Gradus*, as compared with other early varieties, is by far the finest, and *Mr. Laxton* must be congratulated on its production. It was certificated last year, and no Pea has better deserved the honour accorded.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. Shirley Hibberd, W. Holmes, R. Dean, H. Herbst, J. Walker, J. Laing, T. Baines, C. Noble, B. Wynne, J. Dominy, H. M. Pollett, J. O'Brien, A. J. Lendy, W. Goldring, E. Hill, and G. Nicholson.

From the Royal Gardens, Kew, came a group of an extremely interesting character, comprising many rare and beautiful plants, of which the following select few may be noted:—*Primula mollis*, very distinct, with soft cordate leaves and numerous rosy purple flowers; *Wahlenbergia saxicola*, having small bell-shaped bluish white flowers; *Erythraea diffusa*, dwarf and free, bearing numbers of small rosy flowers; *Erpetion reniforme*, a New Zealand plant, bearing pretty Violet-like flowers, purple, tipped with white; *Isoloma hirsuta*, a showy Gesneraceous plant, with hairy leaves and bright red tubular flowers; *Begonia Haageana*, a remarkable plant, the leaves large, and something after the style of *B. metallica*, but lighter, the flowers of great size, with broad pink and white petals, and in dense drooping clusters. The *Nymphaeas*, hybrid *Streptocarpus* and *Lissochilus Krebsi* have been previously described. T. B. Haywood, Esq., Woodhatch Lodge, Reigate (gardener, Mr. Ridout), was awarded a silver Banksian medal for a large collection of beautifully fresh Rose blooms and several boxes of *Odontoglossum crispum* varieties. G. F. Wilson, Esq., Weybridge, exhibited a stem of *Lilium Szovitzianum*, 7 feet high, and bearing eight fine flowers, pale clear yellow, and a few dark dots (vote of thanks). L. Hanson was also shown. C. J. Grahame, Esq., Croydon, showed a box of excellent Rose blooms and fine flowers of *Lilium Kramerii* (votes of thanks). F. G. Tautz, Esq., Hammersmith (gardener, Mr. Cowley), exhibited *Cattleya Gaskelliana superba* and *alba*, both fine varieties; also *Cypripedium Wallisi*, now described to be a variety of *C. caudatum*, and *Dendrobium hercoglossum*, having a profusion of small soft mauve flowers, a white lip, and a black tipped column. G. Firth, Esq., Manningham Thorpe, Bradford, was awarded a cultural commendation for a strong plant of *Grammatophyllum Ellisi* with two racemes of twenty to thirty flowers each. Messrs. Sander & Co., St. Albans, exhibited a plant of *Laelia Eyermanii* described as a supposed natural hybrid between *L. autumnalis* and *L. majalis*, but it did not obtain an award. Dr. Sankey, Boreatton Park, Shrewsbury (gardener,

Mr. Eckford), showed several fine Pansies and Sweet Peas, which were highly commended, and well grown plants of *Orchis foliosa* were sent from Chiswick.

Messrs. J. Veitch & Sons, Chelsea, exhibited a number of plants in pots of *Clethra alnifolia*, a hardy shrub with long spikes of white flowers and graceful habit. It seems well fitted for culture in pots, and a cultural commendation was awarded for it. The dwarf white-flowered *Pratia angulata*, the bell-like *Zenobia speciosa*, a collection of *Rhododendron* and early *Gladiolus* flowers, from the brightest scarlet to the most delicate blush tints and pure white. Several certificates were awarded for other plants, and amongst them was the remarkable *Ostrowskya magnifica* described below. Messrs. W. Paul & Son, Waltham Cross, had a small but choice collection of new Roses, including fine rich blooms of *Grand Mogul*, the *Duchess of Albany*, one of the *La France* type but darker in colour, and pretty white *Moss Rose Little Pearl* (vote of thanks.) Mr. J. Walker, Thame, showed boxes of Sweet Williams, garden Roses, Sweet Peas, and Dutch Honeysuckle (vote of thanks).

Of the larger groups very noteworthy were the *Delphiniums*, *Gaillardias*, and *Amaryllises* from Messrs. Kelway & Son, Langport, Somerset; the effective collection of hardy flowers, comprising Iceland Poppies, *Delphiniums*, *Lilies*, *Pansies*, &c., from Mr. T. S. Ware, Tottenham, and the interesting group of hardy plants and shrubs from Messrs. Paul & Son, Cheshunt, for all of which silver Banksian medals were awarded. Bronze medals were also accorded to Messrs. Laing & Sons, Forest Hill, for a brilliant selection of single and double Tuberous Begonias; to Messrs. Keynes, Williams & Co., Salisbury, for a handsome collection of Roses; and to Mr. T. B. May, Edmonton, for a beautiful group of Ferns.

Messrs. J. Laing & Co. offered prizes for Tuberous Begonias at this meeting, which were won by the following competitors:—Six single varieties.—First, *Sir Edward Saunders*, Fairlawn, Parkside, Wimbledon (gardener, Mr. Newell), with substantial bushy specimens bearing large flowers. Mr. A. Wright, The Gardens, Devonhurst, Chiswick, was second with good plants; and M. Hodgson, Esq., Shirley Cottage, Croydon, was third. The last named was, however, first with three double varieties, followed by Mr. A. Wright.

CERTIFICATED PLANTS.

Ostrowskya magnifica (J. Veitch & Sons).—An interesting herbaceous perennial, a native of Central Asia, and received in this country from Max Leichtlin of Baden, this being said to be the first time it has flowered in England. It is like a gigantic *Campanula*, in the style of *C. macrostyla*, the flowers shallow, bell-shaped, 6 inches in diameter, with eight roundish lobes, the colour being a soft mauve with a slightly darker veining. The stems are strong, with the oblong leaves arranged in fours. It is described as perfectly hardy.

Escallonia philippiana (J. Veitch & Sons).—A neat, dwarf, compact shrub, with small dark green shining leaves, and numerous small white flowers scattered freely over the branches.

Rhododendron Souvenir de J. H. Mangles (J. Veitch & Sons).—One of the "greenhouse hybrid" section, having bold salmon-red flowers, the mouth of the tube purplish, the lobes broad and round.

Allium pedemontanum (T. S. Ware).—An attractive *Allium* certificated under this name was thought by some to be *A. narcissiflorum*, but the Committee adopted the name given above. It has large rosy-purple bell-shaped drooping flowers in small umbels on short stout stems, quite distinct from the majority of the family.

Gymnogramma Pearcei robusta (J. Veitch & Sons).—A compact variety with most elegantly divided fronds, the ultimate divisions linear and bright green, contrasting with the dark stripes, which is slightly powdered like others of the genus.

Pteris tremula elegans (H. B. May).—A variety with the fronds much crested and cut, graceful in habit, bright green, and useful for decoration.

Prunus domestica variegata (Paul & Son).—Distinguished by the neat leaves being broadly margined with gold in contrast with a bright green centre.

Delphinium Ustane (Kelway).—Single, flowers large, pale blue, with a metallic gloss on the inner surface.

Delphinium Prince of Naples (Kelway).—A bold variety with large purple blue flowers, the spike tall and massive.

Carnation Germania (Hooper & Co.).—An excellent pure pale yellow variety, the flowers of good shape and moderate size, capably adapted for cutting.

Cologyne Sanderiana (Baron F. de Rothschild).—Flowers white, except the lip, which is yellow in the centre, the general form suggestive of *C. ocellata*. Racemes long and slightly drooping.

Carpenteria californica (Miss Jekyll).—A handsome shrub related to the *Philadelphus*, but having much larger pure white flowers of five broad petals, and a dense cluster of numerous stamens tipped with large bright yellow anthers, in the centre.

COUNCIL AND GENERAL MEETING.—At the meeting held in the Council Room, Victoria Street, Sir Trevor Lawrence Bart., M.P., in the chair, twelve candidates were duly elected Fellows of the Society. In accordance with the bylaws, all Fellows elected after July 1st pay half the current year's subscription.

In consequence of the great success of the last Apple and Pear Conference, and in order to correct and bring up the reports then published to date, the Council of the Royal Horticultural Society have decided to hold another Apple and Pear Conference at their Gardens, Chiswick, from the 11th to the 18th of October next. Anyone desiring

information in reference thereto are requested to communicate with Mr. A. F. Barron, Superintendent, R.H.S. Gardens, Chiswick.

PRIMULA ROTUNDIFOLIA.

SINCE the advent of *Primula rosea*, which is one of the most charming of early spring flowers, none of the many species introduced from the Himalayas can be compared with the subject of our note, and for which we venture to predict a great future. The accompanying sketch was taken from a plant which flowered in the herbaceous grounds at Kew in April and May of this year, and it is the only figure since Wallich's time, the original being in his "Tentamen Floræ Nepalensis Illustratæ," fig. 32 (uncoloured). The plants flowered at Kew were small, but the size and distinct colour of the flowers, together with the two or three sets of whorls produced, give great promise of something unusual when the plants are fairly developed. It appears to be quite as

FIG. 3.—PRIMULA ROTUNDIFOLIA (REDUCED).

hardly as *P. rosea*, with a similar habit, and requiring much the same kind of treatment. The leaves, as in *P. rosea*, are deciduous, dying off in winter, forming a small compact sulphury white bud, which may be easily protected from the ravages of birds and insects with a few small pebbles or a handful of cocoa-nut fibre. The leaves are orbicular, cordate, crenately toothed, bright green above, and entirely covered with meal on the under side, somewhat resembling *P. Stuarti* or *purpurea* (of Royle); the stalk 4 to 12 inches long, and the blade 3 to 4 inches in diameter. The flower stem grows from 6 inches to a foot in height, with two and often three whorls of bright rosy red flowers as large as those of *rosea*, with a pale yellow ring round the throat. So far as our experience at present goes it will grow as readily as the hardy *P. rosea*, all the capsules being large and promising plenty of seeds. It is found on the Singaloh range from 12 to 18,000 feet above sea level, and from Kashmir to Sikkim. (Syn., *P. odontophylla*, *Wall. Cat.*, 7016).—D.

TWICKENHAM SHOW.

JULY 10TH.

ONE of the most satisfactory Exhibitions held by the Twickenham Horticultural and Cottage Garden Society since its establishment nineteen years ago, was that which attracted so many competitors and visitors to the Orleans House Gardens on Tuesday last, very pleasing evidence of a strong local interest in a district of historical fame for its gardens and gardeners. Seventy-nine classes were provided for plants, flowers, floral decorations, fruit, vegetables, and cottagers' productions, the entries, with very few exceptions, being far more numerous than is general in suburban shows. In some classes where only two prizes were offered there were from eight to twelve competitors, and in the cottagers' classes the entries were even more numerous. The result was that four large tents were filled, one with plants and fruit, another with groups, a third with floral decorations, and the last with the cottagers' exhibits. In addition there were non-competing groups and cut flowers of considerable interest, including excellent Roses from Messrs. W. Paul & Son and Messrs. J. Veitch & Sons, miscellaneous cut

flowers from Mr. Poupert and other growers in the district. The supporters of the Society, the Committee, and their popular Hon. Secretary, Mr. J. J. G. Pugh, who works assiduously and well in its behalf, with Mr. Bates and the widely known horticultural amateur, H. Little, Esq., as chairman, have ample reason to be satisfied with the result of their efforts.

Only a brief notice can be given of the exhibits, for to describe them as they merit would occupy too much space in such a show-crowded issue as the present one. In the first tent a group of Orchids from Mr. H. Little (gardener, Mr. Hill), not in competition, included several fine specimens and varieties from the large collection at The Barons, the same exhibitor winning the first prize for six Orchids, easily defeating Mr. H. James of Norwood. T. Twining, Esq. (gardener, Mr. J. Parsons), had the best six fine-leafage plants in the class provided by Messrs. Hooper & Co., *Latania borbonica* and *Dracænas Shepherdii* being conspicuous specimens. E. J. D. Paul, Esq. (gardener, Mr. Munro), was a close second, an excellent *Adiantum* constituting his finest plant. For six greenhouse plants Mr. H. James won the premier prize by a few points gained on two well flowered Heaths; Mr. Munro's second six comprised a handsome globular *Gloriosa superba*. Mr. Hill was also first with Tuberous Begonias, handsome bushy specimens of fine varieties.

The groups were of exceptional interest, particularly in the class for an arrangement of plants on the turf in a space not exceeding 100 square feet. Three of the four groups entered possessed uncommon merit, but there was little difficulty in selecting the first staged by Messrs. Hooper & Co., and arranged by Mr. Bruekhaus in his most graceful style. Concerning the other two there was some little discussion, but Mr. H. Fordham was ultimately placed second for a group distinguished by its brightness and effectiveness, though rather thin at the back, Mr. Filsell being third with an admirably tasteful arrangement but deficient in colour. The stands of flower baskets of Roses, bouquets, buttonholes, sprays, &c., were exceedingly tasteful in the majority of cases, and the number of competitors rendered the Judges' duties somewhat difficult. Very rarely is such even merit seen in these exhibits, which are chiefly from ladies in the district. With cut Roses J. P. Kitchen, Esq., J. Bateman, Esq., and Mrs. Rust secured the leading prizes.

Fruit was well represented, and the Committee might safely add a third prize to most of these classes. Sir G. Russell, M.P. (gardener, Mr. W. Allan), was first with a collection of six dishes of fruit, including good Black Hamburg and Foster's Seedling Grapes, Peaches, Nectarines, and Strawberries. Mr. C. J. Waite followed. Black Grapes were shown by eight competitors, Mr. W. Allan leading with three even well-coloured bunches of Black Hamburg; and Messrs. H. & E. Wells (gardener Mr. T. Thompson) were second for fine bunches and berries of Madresfield Court, wanting a little more colour. For white Grapes H. Labouchere, Esq., M.P. (gardener, Mr. Fitzwater) won first honours for handsome bunches of Muscat of Alexandria; Mr. Allan following with large bunches of Foster's Seedling. Mr. Allan was first with Peaches, and Mr. Otto Hiehle with Nectarines, both fine fruits. Melons, Strawberries, Tomatoes, and Cucumbers were also represented by good specimens. Vegetables from Messrs. Waite, Coomb, and Garrod secured the prizes for a collection in that order.

BRITISH ORCHIDS.

IN the Journal of August 19th, 1886, appears an interesting communication under the above title, in which the writer, "B.," in referring to *O. maculata*, says:—"The colour of this species varies from nearly white to crimson." It would be interesting to know if one has been met with hitherto pure white. In this part of Somersetshire the species is very plentiful. I have enjoyed many pleasant rambles in search of them, and have found hundreds of all shades, as stated by "B.," from nearly white to crimson; and it was not until a week ago that I found what I think may be termed pure white, not a washed-out colour, but a snow-like spike in a setting of emerald green. A most rigid search in places where the coloured kinds grow by scores has not resulted in the discovery of its fellow. I send you the flower, so that, although it is past its best, you may be able to form some opinion of the purity of the flowers.—W. H. MORTON, *Shepton Mallet*.

[We have some like it, but flowers so pure are not plentiful.]

EPIDENDRUM ATRO PURPUREUM VAR. RANDI.

PLANTS of an Orchid under the above name were shown at the Drill Hall on June 26th last as *E. Randi* both by Sir Trevor Lawrence and Mr. F. G. Tautz, but the Committee determined it to be a variety of *E. atro-purpureum*, though flowers of the latter brought by the gardener, Mr. Cowley, for contrast were very

distinct in form as well as colour. The variety has light brownish lanceolate spreading sepals and petals slightly undulated at the margin, which is of a paler colour. The lip is 1 inch broad, white, with two broad expanded lateral lobes, the centre one rounded, streaked with crimson in the centre, a few similar streaks also being noticeable at the base of the lateral lobes, partly concealed by the broad flat column. The plant shown had a raceme of seven flowers, each over 2 inches in diameter, long narrow dark green leaves, and small conical pseudo-bulbs. The flowers of the form regarded as a typical *E. atro-purpureum* had deep brown narrow sepals and petals, a soft rosy crimson lip with a darker centre, and two small lateral lobes enclosing the column.

Mr. B. S. Williams thus describes *E. atro-purpureum*:—"A very beautiful evergreen species, of free-flowering habit, with ovate or obpyriform rugose pseudo-bulbs, bearing two ligulate-oblong leaves, and terminal erect peduncles, with well furnished

FIG. 4.—EPIDENDRUM ATRO-PURPUREUM VAR. RANDII

racemes of handsome flowers. The cuneate-oblong sepals and petals, incurved at the tips, are green at the base, brown above; the three-lobed lip large, pure white, with a feathered crimson blotch at the base of the roundish flabelliform deeply notched front portion. It blooms in April and May, and lasts five weeks in good condition if the flowers are kept free from damp." He also mentions a variety named roseum with dark rose-coloured lips, which with the forms is a native of Guatemala, New Grenada, and adjoining districts in South America.

PELARGONIUM CUTTINGS.

THE present is a good time to take Pelargonium cuttings where strong early flowering plants are desired next season. Late-struck plants never make such headway early in the season as those do which are rooted early in the season. Cuttings 3 inches long and short-jointed which have not produced flowers are the best to select. Insert them, five or six, in a 3-inch pot, using half loam, leaf soil, and a liberal addi-

tion of coarse silver sand. Make the cuttings firm in the soil, giving a gentle watering. Place the pots in a temperature of say 70°, provide light shade to prevent the leaves flagging. We usually strike ours in a small span-roofed house used for small Crotons. By standing the pots containing the cuttings among the Crotons sufficient shade is obtained by the cuttings, and the daily syringings which the Crotons receive are beneficial to the Pelargoniums. If the stock of any particular variety of Pelargonium is small, and it is wished to increase it rapidly the shoots may be cut into short lengths, one leaf to a joint, fixed firmly into sandy soil in boxes or pans, watered, placed in a cold frame and shaded from bright sun. Most of the cuttings so treated will strike and grow quickly into stout little plants ready for potting with the ordinary stock of plants.—E.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

NEW SERIES.—No. 8.

AMONGST the millions who people our metropolis I am glad to know many readers of this Journal are to be found, and it is therefore of interest to note the change being brought about by the proceedings of the Public Gardens Association, the Kyrle Society, and some local bodies. The cultivation as gardens of numerous hitherto waste or barren patches of land about London is greatly stimulating the pursuit of horticulture in the homes of those folks who are the frequent visitors to these open spaces. They admire and observe, then set to work in their own small domains, and often manage to obtain for them, by gift or purchase, plants and flowers similar to those which have been brought under their notice. Just now some districts of the extensive parish of Lambeth are appealing for more open spaces, pointing out how rich in recreation grounds the folks are on the Middlesex side of the Thames. There is certainly a part of Lambeth, which, though it presents a Pleasant Row, a Paradise Street, a Walnut Tree Walk, and a Hop Garden, is far too crowded with poor habitations. Yet when we get into Kennington, at no great distance, we find quiet nooks which have escaped the influence of the town. Here are gardens where Roses may be cut, and the Camellia, once the pride of adjacent Vauxhall, still blooms, where by favour of the cats and sparrows Peas may be raised, and the Tomato grows in the open air.

It is well whenever possible to open freely to all such smaller spaces as are easy of access, even though parks and commons may be at no very great distance off, because they have special advantages. An example of what may be done in utilising an unlikely spot is to be seen in the garden just opened at Red Cross Street, Southwark, where every effort has been made to give it a green, flowery, and cheerful look; there is indeed, as advertisers say, both "land and water scenery." In the case of some shrubs and plants it must be doubtful whether they will thrive in that air, but the fittest will survive, and new specimens can be introduced. Nelson Square, Blackfriars Road, an open space known to few non-residents, is another that should be turned to account. It has several large Poplars and Scotch Elms, and more Hawthorns than usually occur in London squares. Perhaps at present it is rather too tree-shaded, and only such common cockney flowers as Thrift, London Pride, Irises, and Marigolds succeed in its borders. Several fine specimens of the Guelder Rose testify to the old liking for this flower, and there is a Mulberry, a tree rarely to be met with about London now. I have wondered sometimes why this has so gone out of cultivation, since the suburbs once positively swarmed with Mulberries, and I do not think it at all objects to the soil of the metropolis. Oldys, in 1753, saw immense Mulberries at Lambeth. He reckoned the shadow of one extended over 40 square yards. Might it not be well for our nurserymen to plant more Mulberries, as some think there is an opening for a remunerative silk production in England?

Passing on to St. Mary's and Walcot Squares in the Kennington Road, we discover a fragment of the old St. George's Fields, formerly an almost treeless expanse, where ponds offered the opportunity for the favourite game of duck-hunting, and the grass, stunted in some parts, was rank and thick in others. There are now plenty of trees scattered amongst the houses which stand on what was St. George's Fields. The moist character of the under soil appears in the fact that Willows, Poplars, and Ashes specially flourish. Both these squares, which are not of large size, are at present covered with grass, but they might be formed into pleasant gardens for the crowded neighbourhood. Walcot Square has its Ash, Plane, and Poplar trees, which give it a shady aspect; its companion square is almost open, having only a few shrubs on its sides. I have noticed that in converting these neglected squares into good gardens, it is really necessary not merely to break up but to clear away the stratum which has accumulated in course of years, when plants we should not expect to see come up occasionally from the earth below.

Here I cannot omit mention of William Curtis, pioneer of botanical progress, who, in 1777, took a piece of ground in St. George's Fields, with a view to show living specimens of every British plant he could obtain himself or procure through friends. He was helped by Daines Barrington, and White, his plants being arranged methodically, and clearly labelled in Latin and English. To this collection he then added another of such hardy exotics as were useful as food, medicine, or in the arts. But though he charged only a small entrance fee, the public did not vouchsafe support, so his scheme had to be given up. I thought of Curtis as I surveyed the border of Kennington Park,

near South Street, for there is a little plot of land that offers a veritable *rus in urbe*. Apparently this strip is no proper portion of the park, and so it has been left pretty much to Nature, except the planting of a line of evergreens, probably done when the park was formed. Some large but loosely grown examples of the Box, the Rhododendron (this will not flower as a rule so near London), the Portugal Laurel, the Evergreen Oak, and a species of Euonymus, and running amongst these were such creepers as the common Clematis, the wild Convolvulus, and the Goose Grass (*Galium aparine*). Rising above the grass which filled up most of the space around the shrubs were a variety of native plants, indicating what Kennington Common may have yielded to the herbalists of the olden time. Tallest, perhaps, was the Black Knapweed (*Centaurea nigra*), by which, and a neighbouring Thistle (*Carduus arvensis*) the sparrows seemed to be attracted. Nearly as conspicuous were the crimson tops of the familiar Sorrel (*Rumex acetosa*), and spreading heads of the Yarrow (*Achillea millefolium*). The prevalence of moisture was shown by a clump of Rushes, and there were Trefoil, the Hedge Mustard, and Hedge Garlic, the wild Chamomile, the Bitter Vetch, and other species, but there is no modern Curtis to label them for the public benefit, and a high fence renders specimen-picking difficult. Kennington Park itself is a space of about 17 acres, calling for no special remark, and having an unattractive aspect.—J. R. S. C.

ROSE SHOWS IN 1888.

- July 12th.—Birmingham, Carlton-in-Lindrick, and Winchester.
- " 14th.—Eltham, Manchester, and New Brighton.
- " 16th.—Christleton and Newcastle-under-Lyme.
- " 17th.—Leek and Ulverstone.
- " 18th.—Birkenhead.
- " 19th.—Helensburgh.
- " 20th.—Darlington (National Rose Society).
- " 24th.—Tibshelf.
- " 25th.—Louth.

The above list of Rose show fixtures is the last I propose issuing this season.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

ROSES AT GUNNERSBURY PARK.

Now so much is seen of exhibition Roses, it is a pleasant change to meet with old favourites of bygone days. Several of them are grown in large masses, and others are arched over flower beds. *Chénédolé*, *Baronne Prevost*, *Maiden's Blush*, *Brennus*, *Paul Ricaut*, and others in that form, make the garden sweet and gay. There in large masses are *Géant des Batailles*, *Jules Margottin*, *Souvenir de la Malmaison*, *Coupe d'Hébé*, with several more old favourites, such as *Acidalie* and *Mrs. Bosanquet*. There are many beds of the old *Monthly China*, and a glowing mass of *Cramoisi Supérieure*, also many beds of *Teas*. This suburban home of the Rothschilds is crowded with Roses, which Mr. Roberts grows well, as he does Grapes and all other kinds of fruit and flowers in his extensive charge; but we can only now allude particularly to the Roses.

SEEDLING BRIAR STOCKS.

MAY I be permitted to state a fact respecting the hardiness of the seedling Briar as a stock for Roses? Last November I had cause to move a quantity of Roses in dormant bud which were on seedling Briars. By some mistake, when all the plants were dug up and tied in bundles, three plants of *Gloire de Dijon* were left root upwards on the bare ground, and there they remained exposed to very severe frost for three weeks and a day, when I happened to go and find them. As an experiment I brought them home from the farm where they were and planted them, never thinking they would live, but to my astonishment they are the best maiden plants I have. Give me the seedling Briar as a stock for Roses.—H. I. MACHIN.

THE PERSIAN YELLOW ROSE.

I WAS pleased to read the note on the Persian Yellow Rose. In the garden of the Rev. Lewis Jones at Elford there is a very fine specimen of that lovely Rose. The clump is about 8 feet in diameter, 6 feet high, and forms a huge bouquet of green and gold every summer. The branches touch the ground at its circumference, and altogether it is a floral treat never to be forgotten. We have a good bush of it in the kitchen gardens here, but it will not compare with Mr. Jones'. The Persian Yellow should not be pruned if it is to be seen in its glory. I may say in regard to its lasting properties when cut that I gathered a handful of blooms on the 23rd ult., and I threw them away on the 28th. The flowers retained their colour, but they were withered; they thus lasted five days in water. I only gathered those flowers that were not more than half expanded. I forward a few for test of durability.—J. UDALE.

[The flowers arrived as fresh as possible, the buds expanding in water, and looked well several days after they arrived.]

ROSES IN WINTER.

THE papers by Mr. Bardney become more interesting as they advance, but we realise that he gives his experience with full knowledge, and is liable to forget the learner's difficulty of filling up the details required to complete the sketch. I should be much obliged if Mr. Bardney will inform us in our Journal—1st, How Tea Roses are to be kept at "rest" during September and October when planted out in a house with the roof lights removed? for the rain would fall on them and mild growing weather affect them as if quite in the open, where Tea Roses grow and flower freely then. 2nd, What is the composition, nature, texture, and composition of the soil or compost to be used for such large pots and such young plants? 3rd, Will Mr. Bardney kindly say whether, in growing Roses for cut flowers for market in January, February, and March, it would be most profitable to plant out in side beds near the glass, or to grow them in pots, taking into account all the labour in the latter method?—S. S.

THE BANKSIAN ROSE AS A STOCK FOR MARECHAL NIEL.

EIGHT years ago we had a plant about twenty years old of the white Banksian Rose growing in a greenhouse up a pillar and trained horizontally to wires, near which is a ridge-and-furrow roof. It flowered profusely every April, lasted a few weeks, and then was over for the rest of the year. It then threw out a number of vigorous shoots as stout as good-sized Asparagus, and in June eight years ago three buds were inserted on three of the best placed near the roof of that fine Rose *Maréchal Niel*. We had not thought or heard of this as a suitable stock for the *Maréchal*; it was done more as an experiment, and to our surprise within a fortnight all three buds began growing vigorously, and when about a foot in length all the remainder of the Banksian was cut clean away, several barrowloads of it.

The three young shoots were allowed to grow without stopping, merely tying them to the wires, which were horizontal, as they grew, when at the end of three months (September) one shoot was about 20 feet long and the other two not quite so much. It then ceased to grow any more that season, but in December each shoot was shortened about one-third, and later on in March and April fine Roses were produced from nearly every eye on these shoots, which were about 1½ inch in circumference. When it had ceased flowering the shoots were cut back further to a good eye that had not flowered, and during the summer a large number of fine shoots were made from all dormant eyes, and a large quantity of fine Roses the following spring. Every year since the tree has produced hundreds of blooms. The main stems now average 10 inches in circumference, in the thickest part 14 inches.

In May, after the main flowering, a good deal of the useless and past-flowering wood is cut out, a good washing of softsoap and water is given with the syringe. The roots, which are in a border of loam and manure in the centre of the house, are well deluged with water, and new growth is encouraged during the summer with occasional washings of clean soft water. December we find is a good month for pruning, regulating, and tying the shoots; only the weak wood is cut out and the strong shoots slightly cut back. Two or three times in the spring months, while the Roses are swelling, the bed has a good soaking of weak liquid manure. The *Maréchal Niel* usually throws single buds, but so vigorous have been some of the shoots that three buds, and in many instances five, have been produced, and all developed well. The Banksian as a stock have proved beyond our expectation, and cannot be too strongly recommended. I am trying *Celine Forester* as a stock for the *Maréchal*, but with what result must be left for the future. The Rose on the Banksian was referred to on page 4 by "A Londoner." He was astonished by its vigour, and suggested that a few particulars respecting it would be interesting and suggestive.—A. HARDING, *Orton Hall*.

DISS.—JULY 3RD.

THE forty-fourth Exhibition in connection with this Society was held on Tuesday, July 3rd, in the Cricket Meadow, Roydon Road. Notwithstanding the excessive rainfall of the previous day the Exhibition, as a whole, was the largest and best ever held by the Society. Special features were introduced this year, which had the effect of producing competition from a wide area. In those departments may be mentioned a magnificent collection of herbaceous flowers. Messrs. G. Paul & Son of Cheshunt carried everything before them, being large exhibitors; while Messrs. Gilbert & Son, Ipswich; Mr. Burrell, Cambridge; and Mr. G. Norris, Blo' Norton, were also successful exhibitors.

As usual, there was a most attractive show of Roses, for which the Rev. H. A. Berners carried off the principal awards, showing two boxes, and taking two first prizes for thirty-six distinct trusses and twelve *Teas*, also the National Rose Society's silver medal for the best *Tea*. The Rev. F. Page Roberts also came out well with Roses, taking first prize for best twenty-four single trusses, second for twelve *Teas* or *Noisettes*, and the National Rose Society's silver medal for the best H.P. in any collection. The Rev. A. Foster-Melliar was third in the thirty-six class, second for twenty-four, and second for twelve. The Rev. H. T. Frere took second prize for thirty-six, third for twenty-four, and first for twelve. The Rev. J. H. White taking first for twelve distinct trusses, and the same for six *Teas* or *Noisettes*.

Plants in pots were shown in large numbers, the chief prizes for *Pelargoniums* in bloom going to Rev. H. T. Frere and Miss Taylor. Owing to the late season the show of vegetables and fruit was scarcely equal to former years, but there was a good collection of indoor grown fruit. The cottagers' show, though small, was good, and there was also a small show of honey.

WOODBIDGE.—JULY 4TH

THE thirty-sixth annual Show, held under the auspices of the Woodbridge Horticultural Society, took place in the Abbey grounds, Woodbridge, on Wednesday, the 4th. The weather was not at all satisfactory, as about one o'clock a thunderstorm came on, accompanied by a heavy downpour of rain, which kept many people away from the Show; notwithstanding, there was a large attendance. Besides the horticultural show, there was a military display, plaiting the May pole, &c., by some non-commissioned officers and men of the 20th Hussars. The regimental band performed both morning and evening.

Cut flowers occupied the first place, and of these there was a very good display, though the weather has been most unfavourable for them. Roses made a much better show than last year. In the open class for thirty-sixes Mr. B. R. Cant, Colchester, had an easy win. In the amateurs' classes the Rev. H. A. Berners and the Rev. A. Foster Melliar carried off all the first and second prizes, the former taking no less than four first prizes, and in the open class for twelve Tea-scented and Noisette Roses beating Mr. B. Cant, who was second, and the Rev. A. Foster Melliar third. The twelve Teas shown by Rev. H. A. Berners were exceptionally fine both in size and colour. The names of the twelve were:—Comtesse de Nadaillac, Jean Ducher, Madame Watteville, Innocente Pirola, Marie Van Houtte, Maréchal Niel, Anna Ollivier, Catherine Mermet, Niphotos, Madame Lambard, Hon. Edith Gifford, Souvenir d'Elise.

There was a good show of pot plants. In the classes for stove and greenhouse plants Messrs. Gilbert & Son, Ipswich, beat all comers with two very fine collections. Lord Rendlesham sent some beautiful Orchids. The Duke of Hamilton, Lord Rendlesham, Miss Jones, and Mrs. J. Greenwood showed some very handsome exotic Ferns. There was a very good collection of fruit in spite of the backwardness of the season, Lord Rendlesham taking first prize with a very fine collection.

DURSLEY.—JULY 4TH.

THE first Show of this Society was held in the cricket field adjoining the town under very favourable auspices, the backwardness of the season and the late inclement weather being taken into consideration. Although somewhat late in being formed, the Committee have worked with a will to get up a good Show, and the success which has crowned their efforts is due in no small measure to the energetic Hon. Secretaries, Messrs. H. J. Small and E. W. Cooke. It was wisely decided to give good prizes in a small number of classes, this course of action bringing a fair number of entries from nurserymen and amateurs, some of which unfortunately, owing to the boisterous weather of 2nd and 3rd inst., were unable to show. However, Messrs. Cooling & Sons of Bath, Messrs. Jefferies & Sons of Cirencester, and Mr. S. P. Budd staged their exhibits, and this with a goodly number of local entries made up a show which gave general satisfaction to a large concourse of spectators. To make it still more attractive a fine collection of stove and greenhouse plants from gardens and nurseries in the neighbourhood were arranged along the staging. The superiority of the Bath Roses was apparent at a glance, the storm which passed over the Cotswolds and the valley in which Dursley is situated, damaging many good blooms, seemed to have touched theirs more gently.

In Class 1, twenty-four H. P.'s, three trusses of each, Messrs. Cooling and Son, Bath, were first with remarkably fresh even blooms, comprising A. K. Williams, Madame E. Verdier, Charles Lefebvre, La France, Madame Marie Verdier, Chas. Darwin, Madlle Marie Cointet, Le Havre, François Michelin, Comtesse de Serenyi, Ulrich Brunner (very fine), M. Noman, Mdme. Gabriel Luizet, Magna Charta, Mdme Hippolyte Jamain, Louis Van Houtte, and other similar varieties. Messrs. Jefferies & Son, Cirencester, were second, their best blooms being François Michelin, Annie Laxton, Mdline. Montet, and A. K. Williams—a wet season appears to suit this variety, as it was well shown in several classes.

For thirty-six trusses, H.P., Messrs. Cooling were again first, staging in addition to the varieties already named, Marquise de Castellane, Duchess of Bedford, Violette Bouyer, Victor Hugo, Barthelemy Joubert, Baroness Rothschild, Madame Chas. Wood, John Hopper, Countess of Rosebery, Guillaume Gillemot, Lady Mary Fitzwilliam, Pride of Reigate (the only bloom shown of that variety), Prince Arthur, Countess of Oxford, Helen Paul, Earl of Beaconsfield, Pride of Waltham, and Alphonse Soupert. Messrs. Jefferies were again second, the effect of the weather being apparent on such varieties as Lady Mary Fitzwilliam, but their box contained very good blooms of Earl of Pembroke, Mrs. Baker, Marie Finger, Madame Ducher, and Mary Pochin. In the class for Teas or Noisettes the competition was closer, but the fresher blooms of the Bath firm gained them the first place, their finest blooms being Alha rosea, Paul Nabonnand, Souvenir de Paul Neyron, Devoniensis, Catherine Mermet, Madame Cusin, Innocente Pirola, and Grace Darling. Messrs. Jefferies showed good blooms of Rubens, Perle des Jardins, Etoile de Lyon.

The prizes for amateurs and gentlemen's gardeners were most keenly contested, and here again the Bath Roses came to the front, Mr. S. P. Budd, Bath, staging some of the best blooms in the Show, being followed by Mr. Boner, Angeston, in the H.P. classes, and by Mr. A. B. Winterbottom, M.P., in the Teas or Noisettes. Some interesting exhibits were staged in the classes restricted to amateurs within four miles of Dursley, not employing a regular gardener, and with a better season these classes are sure to be popular ones. Six boxes of Roses were shown, the first being awarded to a hanging basket of Maréchal Niel, the second and third to neat light arrangements.

BATH.—JULY 5TH.

NOTHING but fine weather was wanted to make this a great success, but the promoters had to put up with another great disappointment. Never before has the competition been so keen, and on the whole the quality was surprisingly good. Many complaints were heard on all sides as to the bad effect of the weather upon the blooms, but this was not so apparent among the numerous exhibits from various parts of the country, and at any rate much inferior displays have been held in what were considered more favourable seasons. As will be seen by the prize list, nearly all the great growers were well represented, the Bath fixture always proving popular among exhibitors, and there was a marked improvement in the classes confined to local growers.

NURSERYMEN'S CLASSES.—The premier prizes were offered for seventy-two varieties, single trusses, and with these Messrs. G. Paul and Son, Cheshunt, were first with fine fresh blooms, among which were good examples of Francisca Kruger, Duke of Teck, Victor Hugo, Madame Henry Pereire, and A. K. Williams. Mr. B. R. Cant, Colchester, was a good second, his best being Camille de Rohan, Ulrich Brunner, and Issac Pereire, while the third prize was well won by Messrs. Keynes, Williams & Co., Salisbury. With thirty-six varieties, triplets. Mr. B. R. Cant was first, Messrs. Paul & Son second, and Messrs. Keynes, Williams and Co. again third. Mr. Cant's best blooms were Merveille de Lyon, Niphotos, Reynolds Hole, Duke of Edinburgh, Baroness Rothschild, and La France. The competition with eighteen varieties was exceptionally close and good. Mr. G. Prince, Oxford, was first, Messrs. J. Cooling & Sons, Bath, second, and Messrs. J. Jefferies & Son, Cirencester, third. Mr. G. Prince was also well first with thirty-six triplets, Messrs. Curtis, Sanford & Co., Torquay, being second, Messrs. J. Cooling & Son third, and Messrs. J. Jefferies & Son were highly commended. The class for eighteen Teas or Noisettes was a good one and attracted much attention, but some of the exhibitors, including Mr. G. Prince, neglected to notice the rule that Hybrid Teas were excluded, and had to be disqualified accordingly. Mr. J. Mattock, Oxford, was first, Mr. B. R. Cant second, Messrs. J. Jefferies & Son third, and an extra prize was awarded to Mr. Prince, whose stand included the lovely bloom of Comtesse de Nadaillac, which gained the silver medal of the National Society offered for the best Tea or Noisette in the Show.

AMATEURS' CLASSES.—The best thirty-six varieties, single trusses, were staged by Mr. R. N. G. Baker, Heavitree, who had remarkably massive and fresh blooms. Mr. W. J. Grant, Ledbury, was a good second, and Mr. S. P. Budd, Bath, third. Similar positions were held by these exhibitors in the class for eighteen triplets, and here as in the other classes in which he competed Mr. Budd erred in staging too young blooms. Mr. W. J. Grant had the best twelve Teas, Mr. Budd being second and Mr. Baker third. Other successful exhibitors were Messrs. A. Evans (who was first with twenty-four distinct varieties), C. Taylor, J. Smith, Warminster, and W. Narroway. The principal prizewinners in the local classes were Messrs. S. P. Budd (who among other prizes took the gold medal offered for a stand of twenty-four varieties, distinct), Mr. A. Hodges, Rev. C. C. Layard, Rev. J. E. Gardiner, Mr. Garraway, and Mr. G. L. Hobbs.

OPEN CLASSES.—A special class was provided for twelve Hybrid Perpetuals and twelve Teas or Noisettes, triplets, and with these Mr. S. P. Budd was first, and Messrs. G. Cooling & Son and Mr. B. R. Cant equal second. The best twelve trusses of any crimson Rose were staged by Mr. B. R. Cant, who had A. K. Williams in good condition, in this stand being found the bloom to which was awarded the silver medal as the best hybrid Rose in the Show. Messrs. Curtis, Sanford & Co. were well first with a stand of La France, and also with twelve trusses of any Rose. Other successful exhibitors in these classes for a single variety were Messrs. J. Mattock, A. Evans, Paul & Son, R. N. G. Baker, Keynes, Williams & Co., G. Prince, and Cooling & Son. Messrs. J. Mattock and G. Cooling & Son were the principal prizewinners with bouquets and baskets of Roses, each having highly creditable exhibits.

Messrs. G. Cooling & Son staged, but not for competition, a collection of old-fashioned Roses, which they now make quite a specialty, and their exhibits never fail to attract the attention of visitors. Messrs. Standish, Ascot, arranged a pretty group of Japanese Maples; Mr. Hooper, Bath, had a good collection of Carnations, Picotees, and Pansies; and Mr. A. A. Walters, Bath, also contributed plants and cut blooms.

BRENTWOOD.

THE summer Exhibition of the Brentwood Horticultural Society was held on Thursday, the 5th of July, in the beautiful grounds of Coombe Lodge, Great Warley, the residence of Mr. Edward Ind. The gardens were thrown open to the public, and the weather in the afternoon was all that could be desired. There was a fair Exhibition, but hardly up to the standard of previous years. Roses, considering how late they are this year, were well shown, several good stands being staged, although many blooms showed signs of the rough weather. The premier prize for forty-eight varieties was deservedly awarded to Mr. Frank Cant, who was well ahead of the other three competitors with fine well-built blooms of good substance, the most noteworthy being Etienne Levet, Louis Van Houtte, Prince Camille de Rohan, François Michelin, and two Roses of recent introduction—viz., Viscountess Folkestone and M. Baron. Mr. W. Harrington, gardener to Mr. E. Mitchell of Hornchurch, was placed second, and Mr. Saltmarsh of Chelmsford third. For twenty-four trebles Mr. F. Cant was again first. For twenty-four singles, amateurs residing in Essex, Mr. Wallis of Brentwood was first, showing well-shaped blooms of A. K. Williams,

Countess of Rosebery, and Pierre Notting. For twelve Roses there were seven competitors. Mr. J. C. Quennell being awarded first prize. For six Teas there were four entries, the first prize going to Mr. Harrington, who exhibited a good Innocente Pirola. For three Roses grown by cottagers within five miles of Brentwood, the first prize was won by Mr. Judd of South Weald, who staged in gingerbeer bottles, as the schedule required for this class, three very creditable specimens of La France, Gloire de Dijon, and Dr. Andry.—HORACE VERNET.

CANTERBURY.

As this Society had made a new move this year, which involved the necessity of a fine day, it was with very sad feelings that all who were interested in its success regarded the terrible day that seems to have prevailed all over the country on the previous day. Torrents of rain from morning till night, accompanied with wind, so unceasing that not only did one tremble for the next day, but also for the Roses. How could they stand? Would they not all be dashed and blown to pieces? and would not Teas especially be dragged and untidy? It only shows the extreme care with which Roses are tended by amateurs when I say that nothing of the kind occurred, and that the Show held at Canterbury was held under fair skies and with a capital collection of flowers.

But first as to the locale. The Committee had made a bold effort, and had ventured to solicit the Cathedral authorities for permission to hold it within the precincts, and there, in what is called the Bowling Green, an enclosed piece of garden, sheltered from high winds, and under the shadow of the venerable towers of the grand old pile, the Rose Society's tent was pitched on the green grass, and filled to overflowing with a beautiful collection of flowers. To many of us it brought back the memory of certainly the most picturesque Show that the Society has ever held, so far as the surroundings went, when it met some years ago in Salisbury, in the Palace Gardens; although they were smaller, yet the whole of the surroundings were of the same character, and since the Society moved from the Corn Exchange, which was so admirably adapted for it, their surroundings have not been such as one could wish, and therefore this move was heartily welcomed.

Time brings its changes in all things, and in Rose shows amongst others. One greatly missed one thoroughly good exhibitor, Mr. W. H. Wakeley of Rainham, whose refined and beautiful flowers always added a charm to the Canterbury Show. Others, however, come forward, and so the game is kept up. We find exhibitors who used to show in the smaller classes moving up into higher ones, their place being taken by fresh combatants.

As this is essentially an amateurs' Society (although there are classes for nurserymen also), it is satisfactory to be able to say that the Roses exhibited by private growers were a good deal better than those shown by growers for sale. I think this is easy to be accounted for after such weather as we had the day before. Nurserymen cannot give the attention to individual flowers that the amateur does. His garden is not a forest of Zulu hats or other such like coverings. The amateur looks round the day before and sees what flowers he thinks he will want, and takes special care in shading. This it is impossible for the nurserymen to do, and hence it was that there was a want of freshness about the stands exhibited by nurserymen, while those shown by the amateurs were both clean and fresh. The leading classes amongst them were as follows:—Class 1, twenty-four varieties, one truss of each. Here four exhibitors staged, and one of those unfortunate *contretemps* which sometimes take place even amongst the most experienced exhibitors. The box exhibited by R. L. Knight, Esq., of Bobbing was a long way the best in the Show, but unfortunately it was disqualified for having two A. K. Williams in it. This must have been an inadvertence, for it is so perfectly distinct a Rose that its presence is at once observed. Owing to this mishap, Mr. R. E. West of Reigate carried off the first honours with a very excellent stand of flowers, consisting of Abel Carrière, Marquise de Castellane, Duke of Edinburgh, M. E. Y. Teas, Captain Christy, A. K. Williams, Countess of Rosebery, Général Jacqueminot, Marie Van Houtte, Mrs. Caroline Swales, Mrs. George Dickson (the best bloom of this variety I have seen, it is generally too thin, but this was full and very fresh in colour), Dupuy Jamain, Horace Vernet, Duke of Teck, Henri Lédéchanx, Xavier Olibo, Catherine Mermet, Mlle. Marie Finger, Dr. Andry, Merveille de Lyon, Etienne Levét, and La France. Mr. F. Warde of East Farleigh was second, and Mr. H. Foster of Ashford third. In class 2, for eighteen, distinct, Mr. H. Foster was first with a fine box, containing Madame Gabriel Luizet, Duke of Edinburgh, Jean Larey (a flower unknown to me), Prince Camille de Rohan, Marie Van Houtte, Rubens, Marie Baumann, Madame Eugène Verdier, Beauty of Waltham, Red Dragon, Countess of Rosebery, Baroness Rothschild, Marquise de Castellane, A. K. Williams, Dupuy Jamain, Ipswich Gem (a beautiful dark Rose, which I do not recollect to have seen, and which I thought was a pink Rose, not a dark one), Marguerite Brassac. Mr. F. Warde was second with A. K. Williams, La France (very good), Duke of Edinburgh, Alfred Colomb, Baroness Rothschild, Prince Arthur (very good), Duchesse de Vallambrosa, Marie Baumann, François Michelin, Louis Van Houtte, Etienne Levét, Reynolds Hole, Madame Gabriel Luizet, Prince Camille de Rohan, Belle Lyonnaise, Xavier Olibo, and Duke of Teck. Mr. R. E. West of Reigate was third. In class 3, for twelve Teas or Noisettes, the first prize was taken by R. L. Knight, Esq., with Niphotos, Comtesse Riza du Parc, Madame Kuppenheim, Alba Rosea, Souvenir de Thérèse Levét (a beautiful bloom), Souvenir d'Elise Vardon, Catherine Mermet, Madame Cusin, and Anna Ollivier. Mr. H. Shoesmith of Saltwood, alas! no longer gardener to one whose memory will always be held in loving reverence by all who knew him, Canon Hodgson, had a box

which ran this very close, containing fine blooms of Caroline Kuster, Souvenir de Thérèse Levét, Madame Bravy, Madame Lambard, Marie Van Houtte, Marie Guillot, Comtesse de Nadaillac (a lovely bloom, but not as high coloured as sometimes), Jules Finger, Madame de Watteville, Anna Ollivier, and Princess of Wales. Mr. F. Warde was third. In class 4, for eight varieties, three trusses of each, Mr. R. E. West of Reigate was first with A. K. Williams, Gabriel Luizet, Etienne Levét, Prince Camille de Rohan, Duke of Edinburgh, Baroness Rothschild, and Marie Baumann. In class 5, for twelve varieties, Dr. Ashurst of Farningham was first with fine blooms of Duke of Edinburgh, Etienne Levét, Duke of Teck, A. K. Williams, Merveille de Lyon, Général Jacqueminot, Madame Montel, Baroness Rothschild, and Alfred Colomb. In class 6, for nine Teas, Miss M. Hawksworth of Erdington was first with good blooms of Countess Riza du Parc, Marie Van Houtte, Catherine Mermet, Madame Lambard, Madame Cusin, Madame de Watteville, &c. These were the principal classes amongst the amateurs. The National Rose Society's silver medals for the best Hybrid Perpetual and the best Tea or Noisette amongst the amateur classes were awarded, the first to R. L. Knight, Esq., for a splendid bloom of A. K. Williams, and the other to Mr. H. Shoesmith for the lovely bloom of Comtesse de Nadaillac already mentioned.

Passing to the nurserymen's classes, the first prize was taken for thirty-six varieties by Messrs. Paul & Son, Cheshunt, with moderate flowers, amongst which were, however, good blooms of Lady Alice, the white sport of Lady Mary Fitzwilliam, Madame Joseph Deslois, a rather new Rose of good quality; A. K. Williams, Marie Baumann, Duke of Edinburgh, Duke of Teck, Madame Lacharme, Madame Gabriel Luizet, Alfred Colomb, Prince Camille de Rohan, Niphotos, Xavier Olibo, &c. Mr. B. R. Cant of Colchester was second, and Mr. George Mount of Canterbury third. Mr. Mount was first in Teas with a beautiful box of fresh blooms.

Last year when I attended the Canterbury Show I ventured to prophesy from the appearance of the Roses there that we should have a good season. Like a good many prophecies connected with weather, I was wrong. Yet do I venture once again. I think that unless the unforeseen occurs we may look forward for a first-rate season, such as we have not had for many years. There is no present prospect of blazing hot weather, such as we have had in the beginning of July of late years, and if only thunderstorms keep off Roses must be good.

It remains but to say that the Secretaries, the Rev. H. B. Biron and Mr. Dean, worked with hearty good will, assisted by the Committee, and I can only hope that the financial results may be good.

FARNINGHAM.

THIS prettily situated little Kentish village, situated on the banks of the Darent (dear to all lovers of the gentle art), did not appear in its most attractive form when on Thursday last its annual Exhibition of Roses was held. Lowering skies, heavy thunder showers, with fitful glimpses of sunshine do not form the most fitting accompaniments of a Rose show. Happily as the day wore on the weather improved, and the evening was, comparatively speaking, fine. The Exhibition was held as usual in the ground facing the Hotel, and very little change was made in the arrangements; but changes here, as elsewhere, had taken place in the *personnel* of the Show. The worthy and excellent Chairman, Mr. Dalton, was, alas! no longer with the Society, which will find it difficult to fill the place his death has made vacant. Then in the exhibitors changes had also taken place. Here too Mr. W. H. Wakeley used to show, and his fine Roses were sadly missed. Earl Stanhope, too, did not put in an appearance, and generally there was a slight falling off. This is to be easily accounted for by the backwardness of the season and the unsettled character of the weather, but despite these drawbacks the Roses were well represented, and the quality of the flowers good. There is one comfort in the character of the weather, Roses do not suffer from the heat of the tent, while the bigly coloured Roses show pre-eminently well.

Here, as in other of these local societies, the amateur is especially (and rightly so) considered. It is they who form the backbone of such societies, and their enthusiasm helps forward the general cultivation of the Rose. There are then but two classes where nurserymen entered, and these are open, and, as it will be seen, an amateur occupied the second place.

The class for thirty-six varieties, Mr. Frank Cant, Colchester, was first with a good box, containing Duke of Edinburgh, Madame Cusin, Le Havre, Madame Gabriel Luizet, Lord Beaconsfield, Madame Angèle Jacquier, Ulrich Brunner, Rubens, Comtesse d'Oxford, Niphotos, Dr. Sewell, Souvenir d'un Ami, Magna Charta, Maréchal Niel, Général Jacqueminot, Marie Van Houtte, Sultan of Zanzibar, Devoniensis, Duchess of Bedford, Capt. Christy, Mons. Noman, Lady Mary Fitzwilliam, Dr. Andry, Queen of Queens, Heinrich Schultheis, Madame Eugène Verdier, Marie Baumann, Mrs. John Laing, Madame Alphonse Lavallée, Souvenir de la Malmaison, Horace Vernet, The Bride, Alphonse Souper, La France, François Michelin, and Souvenir d'Elise. Mr. R. E. West of Reigate was second with an excellent stand of Roses, but wanting in variety of colour. Messrs. Geo. Bunyard & Co., Maidstone, were third with good but smaller blooms. In Class 2, for twelve Teas and Noisettes (open), the first prize was awarded to the Rev. F. A. Burnside, of Much Birch, Hereford, for a fine stand of very clear and fresh blooms, consisting of Innocente Pirola, Anna Ollivier, Souvenir d'Elise, Hon. Edith Gifford, Madame Lambard, Maréchal Niel, Souvenir de Gabrielle Drevet (a very pretty new Rose), Marie Van Houtte, Madame Cusin, Rubens, and Madame de Watteville. Mr. F. Cant was second. In Class 3, for

twenty-four varieties, single trusses, Mr. R. E. West had a stand of beautiful flowers, François Michelin (extremely beautiful), Général Jacqueminot, Merveille de Lyon, Duke of Edinburgh, Marquise de Castellane, Prince Camille de Rohan, Etienne Levet, Comte Raimbaud (very fine), Marie Baumann, La France, Camille Bernardin, Duchess of Bedford, Madame Isaac Pereire, Charles Lefebvre, Madame Victor Verdier, Dr. Andry, Comtesse d'Oxford, Louis Van Houtte, Countess of Rosebery, A. K. Williams, Marie Finger, Baroness Rothschild, and Madame Prosper Laugier. In Class 4, for twelve, Mr. A. Mason was first with Baroness Rothschild, Etienne Levet, Niphetos, Louis Van Houtte, Souvenir d'Elise, A. K. Williams, Thomas Mills, Senateur Vaisse, La France, Duchesse de Caylus, Madame Gabriel Luizet, and Duke of Edinburgh. In Class 5, for nine varieties of Teas, the Rev. F. A. Burnside was first with a very pretty box of the following:—Maréchal Niel, Madame Cusin, Souvenir d'un Ami, Madame de Watteville, Hon. Edith Gifford, Marcellin Rhoda, Catherine Mermet, and Rubens. In Class 6, for six Roses of any one variety, dark, Mr. Fuller, The Vicarage, Bexley, was first with fine blooms of Charles Lefebvre; and Geo. Christy, Esq., first for six light, with highly coloured blooms of Maréchal Niel. In Class 8, for twelve varieties, Mr. Fuller was first with good blooms of Dupuy Jamain, Madame Gabriel Luizet, Xavier Olibo, Pride of Waltham, Ulrich Brunner, Merveille de Lyon, Etienne Levet, Louis Van Houtte, Alfred Colomb, Heinrich Schultheis, Baroness Rothschild, and A. K. Williams. In Class 9, for nine varieties of Roses, Mr. T. Barker was first with Senateur Vaisse, Pierre Carnot, Gloire de Bourg-la-Reine, Earl of Pembroke, Thomas Mills, Merveille de Lyon, Dr. Sewell, Madame Hunnehelle, and Prince Camille de Rohan. In Class 10, for six varieties of Roses, Mr. Hardwick was first with Maréchal Niel, Lord Macaulay, A. K. Williams, Annie Laxton, Duke of Edinburgh, and Fisher Holmes. In the class for six varieties of Teas Mr. A. Wallace was first with Etoile de Lyon, Souvenir de Thérèse Levet, Catherine Mermet, Niphetos, Madame Margottin, and Anna Ollivier.

The decoration classes are always a strong feature at the Farningham Show, and although some of those who used to send some of the most beautiful arrangements have passed away, yet there was no diminution in the interest; and some most beautiful stands, bouquets, sprays for ladies' dresses, buttonhole bouquets, &c., were set up. The principal honours were divided between Mrs. Hugh Smith, whose set of three stands for centre of dinner table was most tastefully arranged; Miss Hassell, who carried off no less than four first prizes; Mrs. Mugeridge, and Miss Reynolds. There were eight tables arranged, some of which were very pretty, others the reverse. Mr. Seal carried off the first prize, Miss Hassell the second, and Mr. Abbott, gardener to Sir W. Hart Dyke, the third. There was a fair display of cottagers' productions, but not so good as I have sometimes seen them. Strawberries were very fine, but though Farningham is in the very centre of the Strawberry district, the only kind exhibited was Sir Joseph Paxton. On my way to the station I dropped in for a short visit to the Home of Flowers, where Mr. Cannell has always something to show one. It is impossible to exaggerate the beauty of some of the flowers which I saw. I had only time to run through the grand Pelargonium house, the Ivy-leaved Pelargoniums, and the single and double Begonias, but what a blaze of beauty there was! Then when one recollects the old Ivy-leaf Pelargonium, and sees the wondrous trusses of double flowers, such as Madame Thibaut, Souvenir de Charles Turner, and some especially beautiful colours which are yet to come out, we wonder what will follow. The same may be said of Begonias. The marvellous single and double varieties are bewildering in their beauty, variety of colour, &c. There was also a grand new Heliotrope which seemed to me to be finer than anything I had seen. Had I been able to remain I should doubtless have seen many wonderful things, but I saw enough to convince me that the Home of Flowers is in no danger of losing its reputation.

HITCHIN.

OWING to the indefatigable zeal of the Secretary of the Hitchin Rose Society, the Rev. F. H. Gall, who quaintly described himself as the most enthusiastic and the most unsuccessful of Rose exhibitors, this Society still maintains steadily its position, and around its many discouraging circumstances succeeded in bringing together a goodly number of exhibitors. Its principal local exhibitor, Mr. E. B. Lindsell, was this year not able to hold the position which he under ordinary circumstances would be able to maintain, but his garden being exposed and of a heavy character his blooms were not open. I went through it the night before in order to advise as to whether he should exhibit in the highest class at the National on Saturday, and I was quite surprised at the backwardness of his plants. Most vigorous and healthy they were, indeed could not be well better, each with fine fat buds, but even then as it was blowing hard I could see how terribly they were switched about, and how impossible it would be for him to attempt the higher flight to which he aspired. I also had an opportunity of seeing Mr. Gall's new garden, where I think he ought and will grow Roses better than he has ever done. He is one of those conservatives who stick to the standards, but if he goes in for dwarfs I see no reason why with his enthusiasm he should not take a higher position than he has hitherto done. Other good exhibitors were present in the—(I was going to say person—but to my great regret he himself was absent)—well, in Roses of my old friend, Mr. Curtis of Chatteris, the Rev. W. H. Jackson of Stagsden, Dr. King of Madingley, and the Rev. O. Fisher, known to many Rose growers by his excellent little book on Rose culture. Thus there were the elements of a good Show, and despite of many drawbacks it deserved that character. After the judging was over the Rev. F. H.

Gall entertained the exhibitors at a luncheon at the "Sun Hotel," a hostelry well known to travellers of the olden time.

The Show was held as before in the grounds of J. Delmé Ratcliffe, Esq., and the tent was fairly well filled. There were three competitors in the nurserymen's classes—Mr. Burch of Peterborough, Mr. Burrell of Cambridge, and Messrs. Paul & Son. In the highest class for forty-eight single the prizes were awarded in the order named. Messrs. Burch's flowers consisted of Madame Victor Verdier, Niphetos, François Michelin, Souvenir de Paul Neyron, Perle des Jardins, Magna Charta, Mlle. Eugénie Verdier, Marie Van Houtte, Duchess of Bedford, Mons. Noman, Xavier Olibo, La France, Constantine Tretiakoff, Madame Lambard, Madame Charles Wood, Madame G. Luizet, Madame Bravy, Louis Van Houtte, Barthélemy Joubert, Rubens, Star of Waltham, Lady Mary Fitzwilliam, E. Y. Teas, Violette Bouyer, Catherine Mermet, Marguerite de St. Amand, Senateur Vaisse, Comtesse de Serenye, Marie Baumann, Queen of Queens (dingy), Captain Christy, Camille Bernardin, Madame Willermoz, Jean Ducher, Alfred Colomb, Maréchal Niel, Madame Cusin, Marie Verdier, Anna Ollivier, Louis Van Houtte, Grace Darling, A. K. Williams, Innocente Pirola, Prince Camille de Rohan, and Comte de Paris. In class 2, for twelve trebles, Mr. Burch was again first with Marquise de Castellane, Niphetos, François Michelin, Madame G. Luizet, Marie Verdier, Madame Bravy, Lady Mary Fitzwilliam, Ulrich Brunner, Henri Schulteis, Anna Ollivier, Innocente Pirola, and Exposition de Brie.

In the amateurs' class the first prize for twenty-four singles was awarded to Mr. J. L. Curtis of Chatteris for a beautiful stand, containing A. K. Williams, Baroness Rothschild, Louis Van Houtte, Her Majesty (a very good bloom, uncommonly like Marie Cointet), Marie Cointet, Etienne Levet, Ulrich Brunner, Marguerite de St. Amand (very fine), Alfred Colomb, Niphetos, Duke of Edinburgh, Catherine Mermet, Comtesse de Nadaillac (very lovely), Duke of Wellington, Madame Cusin, Madame G. Luizet, Reynolds Hole, Le Havre, Innocente Pirola, François Michelin, Niphetos, Jean Ducher, and Madame Victor Verdier. Mr. E. B. Lindsell, second, had an excellent box, containing amongst others a perfect bloom of Charles Lefebvre, which gained the National Rose Society's silver medal for the best Hybrid Perpetual in the amateurs' class, as did Mr. Curtis's Comtesse de Nadaillac for the best Tea. Mr. G. Fowler, of Woodford, was third. In Class 4, for twelve trebles, Mr. E. B. Lindsell was first with fine blooms of Charles Lefebvre, Maréchal Niel, Madame Gabriel Luizet, Lady Mary Fitzwilliam, Countess of Rosebery, Duke of Edinburgh, Grace Darling, A. K. Williams, Marie Van Houtte, Dr. Sewell (very good), and Marie Finger. The Rev. W. H. Jackson of Stagsden was second. In the class for eighteen singles Mr. Turner was first with good blooms of Madame G. Luizet, Etienne Levet, Alphonse Soupert, A. K. Williams, Magna Charta, Dr. Sewell, Duke of Wellington, Ulrich Brunner, Dr. Andry, Lady Mary Fitzwilliam, François Michelin, Comtesse d'Oxford, Marquise de Castellane, Fisher Holmes, Dupuy Jamain, Mons. Noman, Annie Laxton, and Madame Lambard. The Rev. F. H. Gall was second, Marie Baumann, Dupuy Jamain, La France, Abel Carrière, M. Alphonse Soupert, Reynolds Hole, Lady Mary Fitzwilliam, Merveille de Lyon, Captain Christy, Duchess of Bedford, Souvenir de Thérèse Levet, John Stuart Mill, Masterpiece, and Ulrich Brunner. The Rev. J. Lambert was third. In the class for twelves, the Rev. O. Fisher was first with La France, Etienne Levet, Comtesse de Nadaillac, A. K. Williams, Her Majesty, George Moreau, Souvenir d'Elise, Abel Carrière, Mde. G. Luizet, Ulrich Brunner, Catherine Mermet, Madame I. Pereire. The Rev. Dr. King was second, and Mrs. Times third. In the class for nine Miss Annie Lucas was first with A. K. Williams, Victor Verdier, Horace Vernet, Captain Christy, Louis Van Houtte, Merveille de Lyon, Dr. Andry, Marquise de Castellane, and Duchess of Bedford. Miss Bailey Denton was second. In the class for sixes the Rev. E. L. Carey was first with Rubens, Madame Lambard, Souvenir de Paul Neyron, Marquise de Castellane, and Beauty of Waltham.

In the classes for Teas some very beautiful flowers were shown, and considering the showery weather, in remarkably clean condition. The Rev. Dr. King was first for eighteen with Marie Van Houtte, Caroline Kuster, Madame Lambard, Maréchal Niel, Princess of Wales, Catherine Mermet, Souvenir d'Elise, Souvenir d'un Ami, Madame Bravy, Jean Ducher, Adam, Hon. Edith Gifford, Francisca Kruger, Comtesse de Nadaillac, Souvenir de Paul Neyron, Rubens, Anna Ollivier, and Niphetos. The Rev. W. H. Jackson was second. In the class for twelve Teas Mr. Jackson was first with fine blooms of Francisca Kruger, Souvenir de Madame Pernet, Souvenir d'un Ami, Catherine Mermet, Maréchal Niel, Comtesse de Nadaillac, Innocente Pirola, Hon. Edith Gifford, Madame Cusin, Rubens, and Madame Lambard. Mr. E. B. Lindsell was second. In the class for six Teas the Rev. O. Fisher was first with Grace Darling, Caroline Kuster, Catherine Mermet, Souvenir d'Elise, Comtesse de Nadaillac, and Souvenir d'un Ami. In the class for any other variety Mr. Curtis was first with Marie Cointet, and Mr. Wilkins second with A. K. Williams. For the best six Teas of any one variety Mr. Curtis was first with Caroline Kuster, and Mr. Parker second with Maréchal Niel. The silver medal for the best Hybrid Perpetual was awarded to Mr. Lindsell for Charles Lefebvre (a magnificent bloom), and that for the best Tea to Comtesse de Nadaillac. Unfortunately the weather was not propitious, heavy showers having fallen all through the morning, and the marvel was that with such weather the flowers were shown so clean and perfect.

MAIDSTONE ROSE CLUB.

THE annual Exhibition of Roses in connection with this Club was held in a marquee in the grounds of the Old Palace last week. The

attendance, which was very fashionable, was not so large as last year, owing no doubt to the heavy showers which came down at frequent intervals during the day. Had the weather been fine a better place could not have been found in which to hold the Show than in the picturesque grounds of the Old Palace, which have recently been greatly improved. The arrangements were carried out under the superintendence of the indefatigable Hon. Secretary (Mr. Hubert Bensted) and a Committee, and, as far as the weather permitted, gave every satisfaction. The exhibits were judged by Messrs. J. D. Pawle and G. Bunyard, who awarded prizes of the value of about £25, besides the valuable cup presented by the Mayor. The Judges were assisted in the ladies' department by Mrs. R. L. Knight of Sittingbourne. The Mayor's cup, which was an excellent specimen of the silversmith's art, was won by Mr. R. L. Knight of Sittingbourne, for one truss each of the H.P.'s, and twelve Tea-scented Noisettes. Mr. T. Hollingworth of Turkey Court, who is famous for his Roses, exhibited several stands of Roses not for competition, as did also Mr. Bunyard and Mr. Frost. Mr. Bunyard's Shirley Poppies were much admired, and Mr. Frost's Spanish and English Irises and a plant of Rose d'Amour received their share of attention. Groups of splendid decorative plants were also kindly sent from Vinters.

The following is the prize list:—Twenty-four varieties, any kinds, one truss of each—First, Mr. F. Warde; second, Mr. R. E. West. Twelve varieties, Tea-scented and Noisette, one truss of each—First, Mr. H. Shoesmith. Twenty-four varieties, twelve Hybrid Perpetuals and twelve Tea-scented and Noisette, one truss of each—First, Mr. R. L. Knight, cup; second, Mr. F. Warde; third, Mr. A. T. Killick. Eighteen varieties, one truss of each—First, Mr. H. Foster; second, Mr. R. E. West. Twelve varieties—one truss of each—First, Mr. R. L. Knight; second Messrs. Ashurst and Tucker; third, Mr. J. Smythe. Twelve varieties, Tea-scented and Noisette, one truss of each—First, Mr. R. L. Knight; second, Messrs. Ashurst and Tucker. Eight varieties, three trusses of each—First, Mr. F. Warde; second, Mr. R. E. West. Nine varieties, one truss of each—First, the Rev. H. B. Biron; second, Mr. H. Monckton. Six varieties, Tea-scented and Noisette, one truss of each—First the Rev. H. B. Biron; second, Mr. H. Monckton. Six varieties, three trusses of each—First, the Rev. H. B. Biron; second, Mr. A. T. Killick. Six varieties, Tea-scented and Noisette, three trusses of each—First, Mr. R. L. Knight; second, the Rev. H. B. Biron; third, Mr. H. Shoesmith. One variety—First, Mr. H. Shoesmith; second, Messrs. Ashurst and Tucker and Mr. R. E. West, equal. A device consisting of Roses combined with Ferns or other foliage—First, Miss M. E. Laurence; second, Mrs. Killick. Shoulder-knot consisting of Roses combined with Ferns or other foliage—First, Mrs. Knight; second, Mrs. H. B. Biron; third, Mrs. Tasker; fourth, Miss E. Byrant. Buttonhole bouquet consisting of one or more Rose huds—First, Mrs. H. B. Biron; second, Miss Mercer; third, Mrs. Tasker; fourth, Miss Cecil Laurence.

SUTTON.

Two circumstances sadly interfered with the extent of this Exhibition—the terrible character of the weather, and the fact that it was held on the day preceding the National Rose Show at the Crystal Palace, hence of all the nurserymen who had promised to put in an appearance only one, Mr. Rumsey, came, and several amateurs whom we are accustomed to see in good force at Sutton, such as Messrs. Slaughter and Cbeals, were absent. This arises from various causes. Amateurs cannot often have a double supply of boxes, and hence they have to wait until the Exhibition is closed; then it is too late to get home to cut their Roses and stage them for the next day, nor can they very well leave their gardeners behind, for they want all the force they can to get their boxes ready for the Exhibition. Rose-showing is not an easy game to play, and as I watched the energetic movements of my friend, Mr. Ernest Wilkins, who had got up by gaslight, rushing about in all directions through his garden, gathering a flower here and another there, I felt that I had rather not be an exhibitor. And then what weather! torrents of rain dashing the flowers, and our hopes too at the same time, and teaching us that in this climate we can never count upon anything. We had all anticipated a grand Rose season, but unless the weather soon clears up we shall again have to mourn over disappointed hopes.

Well, notwithstanding all this, there was a very excellent display of Roses at the Sutton Show. The local classes were represented by much better blooms, and the Roses exhibited were of excellent quality all round. Considerable interest was attached to a new class, the prizes for which, amounting to 6 guineas, were given by a member of the Society. In the terms of the schedule it was for the best and most tastefully arranged box of Roses, with added foliage of Ferns, &c. Any number of blooms may be staged, but not more than three of one variety, and not less than twelve varieties. Persons have over and over again found fault with the usual method of improving it, and have tried to suggest plans for its improvement, but I do not think that much progress has been made. The box which obtained the first prize was that of Mr. Ernest Wilkins, and the added foliage was simply Maidenhair Fern. It was very pretty, but after all one could not help saying, "Well, if I want to see the Roses I had rather that was out of the way." There were six competitors in this class, and their boxes formed an attractive feature of the Show.

In the class for twenty-four varieties the first prize was awarded to E. M. Bethune, Esq., of Denne Park, Horsham, for fine blooms of Maurice Bernardin, Charles Darwin, Violette Bouyer, Dupuy Jamain, Catherine Mermet, Marie Verdier, Général Jacqueminot, Lady Mary Fitzwilliam,

Fisher Holmes, Xavier Olibo, Madame Isaac Pereire, Camille Bernardin, Ulrich Brunner (an enormous bloom), Senateur Vaisse, A. K. Williams, Captain Christy, Marie Baumann, Duke of Edinburgh, Madame Gabriel Luizet, Victor Verdier, and La France. The second was awarded to R. E. West, Esq., Reigate, for Madame Gabriel Luizet, Senateur Vaisse, Pride of Waltham, Marquise de Castellane, Countess of Rosebery, A. K. Williams, Duke of Edinburgh, Marie Verdier, Prince Camille de Rohan, Baroness Rothschild, Comte de Raimbaud, Violette Bouyer, Dr. Andry, Madame Lambard, Louis Van Houtte, Marie Baumann, Le Havre, Madame Isaac Pereire, Comtesse d'Oxford, Prince Arthur, and Merveille de Lyon. In class 3, for twelve doubles, Mr. West was first with clean fresh blooms of Baroness Rothschild, Marie Baumann, Louis Van Houtte, Dr. Andry, John Hopper, Alfred Colomb, Comtesse d'Oxford, Duke of Edinburgh, Madame Gabriel Luizet, Charles Lefebvre, Marie Bernardin, and Marquise de Castellane. Mr. Bethune was second with Hon. Edith Gifford, Marie Verdier, Duchess of Bedford, Alfred Colomb, Duke of Edinburgh, A. K. Williams, Madame Victor Verdier, La France, Ulrich Brunner, Charles Lefebvre, and Madame Gabriel Luizet. In class 4, for eight varieties, three of each, the first prize was taken by E. B. Lindsell, Esq., for fine blooms of Senateur Vaisse, Madame Gabriel Luizet, A. K. Williams, Rubens, Victor Verdier, Duke of Edinburgh, Comtesse d'Oxford, and Charles Lefebvre. In class 5, for twelve distinct Teas or Noisettes, the Rev. W. H. Jackson of Stagsden Rectory, Bedford, was first with good blooms of Francisca Kruger, President, Etoile de Lyon, Hon. Edith Gifford, Marie Van Houtte, Rubens, Comtesse de Nadaillae, Souvenir d'Elise, Souvenir d'un Ami, Madame Cusin, and Catherine Mermet. The Rev. F. R. Burnside of Much Birch Rectory, Hereford, was second, and it only shows the staying powers of Teas in such weather as this to say that it was the identical twelve with which he took first prize the day before at Farningham. They had gone off a little, as might have been expected, but they were still very beautiful. In class 6, for nine double trusses, Mr. E. C. Cuthell of Cbapel Croft, Dorking, was first with Le Havre, Mrs. Baker, Duke of Edinburgh, A. K. Williams, Baroness Rothschild, François Michelon, Ulrich Brunner, Pride of Waltham, and Alfred Colomb. Mr. Ernest Wilkins was second with François Michelon, Prince Arthur, Ulrich Brunner, Marie Baumann, Charles Lefebvre, Camille Bernardin, Dupuy Jamain, Comtesse d'Oxford, and Etienne Levat. The Rev. W. Wilkins of Shirley Vicarage, Croydon, and the Rev. F. H. Gall of Hitchin were equal thirds. In class 9, for six Teas and Noisettes, Mr. E. C. Cuthell was first with a very fine bloom of Alha Rosea, also Madame Lambard, Souvenir d'Elise, Innocente Pirola, Marie Van Houtte, and Maréchal Niel. In the class for twelve of any one sort, Mr. G. Fowler of Woodford, Essex, was first with a fine box of Ulrich Brunner, very high in colour and altogether excellent. Mr. Cuthell was second with Etienne Levat, and Mr. Jackson would have been awarded third for a good box of Caroline Kuster, but as there were only three competitors no third prize was awarded. The most keenly contested class amongst the local exhibits was that for the ladies' challenge cup, which must be taken by the same exhibitor two years in succession before it becomes his property. It was won by C. Walter, Esq., for the first time with an excellent stand, containing good blooms of Victor Verdier, Prince Arthur, Dr. Andry, Etienne Levat, Général Jacqueminot, and Marie Verdier.

The classes for bouquets, baskets of Roses, sprays for ladies' dresses, brackets, &c., are always well contested at Sutton, and this year was no exception to the rule. Some very pretty designs were shown, the principal prizewinners being Mrs. Ernest Wilkins, Mrs. Luke, Miss Fisher, &c. There is no show where the arrangements are better than at Sutton. This year the Committee had determined to come back to the Public Hall instead of holding it in a tent, as has been done during the last few years. It was well they so decided, for heavy rain fell, and would have made the ground most uncomfortable, and despite many drawbacks they may congratulate themselves on a good Show held in a dry place.

HEREFORD AND WEST OF ENGLAND.

THE twenty-second annual Exhibition of Roses was held, as usual, in the Shire Hall, Hereford, on Tuesday, July 3rd, and we are glad to be able to report that this, the oldest Rose Show in the kingdom, and as a matter of fact, paradoxical as it may sound, the parent as well as the affiliated daughter of the National Rose Society, proved worthy of the recognised position and popularity she has so long enjoyed. The date of the Show undoubtedly was fixed too early, but then for the last two years it has been fixed much too late, and managers of Rose shows after all are but human and liable to make mistakes. It is a matter, therefore, of unmixed congratulation that at the last exhibitors, both nurserymen and amateurs, turned up from all parts of the kingdom with collections, especially Teas, rarely equalled, giving the pleasing result of a capital Exhibition successful throughout each of its departments. We now subjoin a list of the leading collections, giving from time to time a few remarks, for which, we trust, space will be found.

Class A, nurserymen, seventy-two varieties.—First, Mr. Frank Cant, Colchester: H.P.'s, Captain Christy, Sultan of Zanzibar, superb in colour; Violette Bouyer, A. K. Williams, perfect. Tea Madame H. Jamain. H.P.'s, Duke of Wellington, Duchess de Vallambrosa, Magna Charta, Merveille de Lyon, Louis Van Houtte, Madame E. Verdier, Ulrich Brunner, Duke of Teck, fine; Lady Mary Fitzwilliam, shown everywhere well; Crown Prince, Her Majesty, Pride of Reigate, a motley interloper; Edouard Morren, Charles Lefebvre. Tea Devoniensis. H.P.'s, Alfred Dumesnil, exquisite; Madame Nacbury. Tea Rubens. H.P.'s, Duke of Edinburgh, Marquise de Castellane, Fisher Holmes. Tea Madame Bravy. H.P.'s, Mrs. John Laing, Marie Rady, Marguerite

de St. Amand. Tea Madame Cusin. H.P.'s, Althouse Soupert, Madame Ducher. Tea Madame Lambard. H.P. Dr. Sewell. H.T.'s Countess of Pembroke, La France, Dupuy Jamain. Tea Catherine Mermet. H.P. Général Jacqueminot. Tea Bride. H.P. Thomas Mills. H.T. Grace Darling. H.P. Madame Charles Wood. Tea Jean Ducher. H.P.'s Annie Laxton, Dr. Andry. Tea Souvenir d'un Ami. H.P.'s Etienne Levet, Madame H. Jamain, Anguste Rigotard. Tea Madame de Watteville. H.P. Countess of Oxford. Tea Marie Van Houtte. H.P.'s Rosieriste Jacobs, M^{me}. Rothschild, Prince Camille de Rohan. Noisette M^{me} Caroline Kuster. H.P.'s Glory of Cheshunt, Ferdinand de Lesseps, Madame G. Luizet, Mat Baron. Tea Souvenir d'Elise. H.P. François Louvat. Tea Princess of Wales. H.P.'s Duke of Connaught, Egeria, Constantine Tretiakoff, Horace Vernet, Madame Noman, Prince Arthur. Messrs. Cranston & Co. took second honours, and Messrs. Keynes, Williams & Co. third in this division. The same order was followed in Class 2, thirty-six varieties.

In class 3, forty-eight varieties, single trusses, Mr. Charles Turner was placed first with a fine and even collection. Messrs. George Cooling and Sons second, and Mr. Charles Whiting third. Strange to say precisely the same order was followed in class 4, twenty-four varieties, three of each. Class 5, twenty-four varieties, Mr. Thomas Griffiths, Tillington, was the only exhibitor, but admirable in almost every specimen. The Tea and Noisette classes of nurserymen and amateurs were specially conspicuous both as regards the number of the exhibitors and the superb quality of the exhibits; it is not too much to say that there really was not a slovenly or inartistic collection staged. Certainly nothing shows more how rapidly these lovely Roses are advancing in favour with the public than the extraordinary improvement to be noticed everywhere in this direction. Here, again, class 17, Mr. Frank Cant was first with an absolutely faultless collection, among which Marie Van Houtte, Souvenir de Gabrielle Drevet, Princess Beatrice, new and very good; and Jean Ducher, were chiefly commendable. Second, Mr. Charles Turner. Third, Messrs. Cooling & Sons. Class 18, twelve varieties, three of each, Mr. Frank Cant first, Messrs. Cranston & Co. second.

In eighteen varieties of any one Rose H.P. Lady Mary Fitzwilliam in purity and softness of tone and symmetry was unapproachable; H.P. François Michelin second, and Mons. Noman and La France equal third. Amateurs in Herefordshire are late; besides, their Roses have suffered much from local thunderstorms; still, Mr. Grant well sustained the credit of his county and carried off the first prize for thirty-six varieties single trusses and the N.R.S. silver medal. His collection, which wonderfully improved afterwards, comprised the following varieties:—H.P. Sénateur Vaisse, Duchesse de Vallambrosa, Duchess of Bedford (exquisite), Miss Hassard, Louis Van Houtte, Tea Souvenir d'un Ami (superb), Alphonse Soupert, Mons. Noman, A. K. Williams, Lady Mary Fitzwilliam (everywhere good), Constantine Tretiakoff, Mr. John Laing (great acquisition), Violette Bouyer, Prince Arthur (fine colour), Maréchal Niel, Madame Eugène Verdier, Tea Niphotos, H.P. Ulrich Brunner (grand), Tea Hon. Miss Gifford, H.P. Duke of Teck, Tea Homère (wonderful colour), H.P. Abel Carrière, M^{lle}. Eugénie Verdier, Henri Schultheis, Marie Cointet, Tea Amazone, H.P. Elie Morel, Teas Catherine Mermet, Madame Cusin, Souvenir d'Elise Vardon (splendid), Duke of Edinburgh, Marie Van Houtte, Madame Gabriel Luizet, Tea Comtesse Nadaillae, H.P. Marquise de Castellane, Charles Lefebvre. Dr. Budd carried off second prize with blooms little inferior; indeed, in the two next classes the position of these exhibitors was reversed. Mr. J. H. Arkwright took both third prizes. In class 19, single trusses, eighteen varieties, the leading prizewinners were Rev. F. R. Burnside, Mr. Grant, and Dr. Budd; and class 20 twelve varieties, three of each, Mr. E. Claxton, and equal second Rev. F. Burnside and Mr. Grant in the order named. The premier Tea bloom, Innocente Pirola, was taken from Mr. Claxton's box. It only remains to state, as object of public interest, that in the decorative department (a leading feature in the Hereford Rose Show) Messrs. Perkins & Son carried off in their usual artistic style the special prizes given by the Marquis of Bute.

Messrs. Smith of Worcester staged a splendid collection of herbaceous plants, the sombre colours of which contrasted strikingly with the bright reds and pinks everywhere prevailing. The Judges were:—In the nurserymen's division the Rev. F. R. Burnside, Rev. J. A. Williams, and Mr. W. Grant. In the amateur division Mr. W. Williams and Mr. Frank Cant.—HEREFORDSHIRE INCUMBENT.

ROSES AT WIMBLEDON.

At the Summer Exhibition of the Wimbledon Horticultural Society one of the marquees was chiefly occupied with Roses. Though the best stands did not exceed in merit some of previous years the average of the Show was higher, and the collections staged better; only in a few stands were the blooms "flopped" down on the board or moss, thus spoiling their appearance. Mr. C. Gibson, Marden Park, staged his blooms admirably, winning the chief prizes in the classes for twenty-four and two ve blooms, Mr. C. Northover closely following in the former and Mr. Alderman in the latter. Mr. Northover won seven prizes out of eight exhibits in other classes, and Mr. J. Coleby secured first prizes in the amateurs' classes for two ve and six blooms, also for six of any variety, with Louis Van Houtte, Mr. W. B. Faulkner being second in this class with Merveille de Lyon. Mr. Conway and Mr. J. W. Wright were also successful exhibitors. The effects of drenching rains were visible on many blooms, notably of the light varieties, the darks showing to much greater advantage. Messrs. J. Cheal & Sons, Crawley, were prizetakers in the open class, and Messrs. James Veitch & Sons contributed boxes of

handsome blooms not for competition. The Rose tent also contained a splendid collection of hardy flowers from Messrs. D. S. Thompson and Son, Wimbledon.

THE DIFFICULTIES AND DUTIES OF GARDENERS.

UNDER the above heading your able correspondent, "An Old Servant," brings forward a subject that will cause many to think seriously, and probably not a few to discuss the matter in your columns. Your correspondent mentions a "deficiency of compliments and praise" as often being the cause of gardeners giving up their situations. That I know is frequently the case. It is also applicable to under gardeners, which is my reason for addressing you. If gardeners in general would give the matter serious consideration, and remember how happy it makes them feel when they receive recognition of their endeavours from their employers, I think there are many who would mete out a little more to their subordinates than they do generally. I have served under gardeners who never think of praising a young man, because they imagine it would make him vain. On the other hand, I have served under others who have always applauded perseverance.

The former was continually deploring that he was not complimented and treated as he should be, while I never remember hearing the latter murmuring at all. I have had many arguments on the "servant" question with both parties, but as I have always taken your correspondent's view of it I will not further allude to it, but expect to see more in your columns. The apprenticeship I am afraid is against us. Head gardeners, please remember that as you value the praise of your employer, so is yours valued by your subordinates.—H. S.

FLOWERING PLANTS IN SEASON.

AT no period of the year is there a better display of the plants grown for their floral beauty than this. Abundance of flowers is everywhere secured, both indoors and out, and will continue so for weeks to come. It is with indoor plants that these notes are confined to, and if a show is desired, whether for conservatory or for house decoration, there is ample variety and colour to please the eye, and no lack of plants to select from. Only a few of the many will be noted here, but these are popular and good, and scarcely require any further recommendation. In the stove the beautiful Stephanotis will at once attract notice by its perfume, and on account of its usefulness should be grown by everyone. Allamanda Hendersoni covered with rich amber flowers is always admired. Another good plant is Tabernemontana coronaria fl.-pl., its white flowers being so well adapted for buttonholes. In the intermediate house Bougainvillea glabra thrives well, and at this season is at its best. It can be cut freely and repeatedly. Gloxinias are very effective, whether grouped or mixed with graceful foliage plants. Caladiums mixed with them make a splendid show. A good plant is Impatiens Hawkeri, of strong habit; its dark magenta flowers render it very conspicuous.

Turning to the greenhouse abundance of flowers can be seen, first being the Carnation Souvenir de la Malmaison in 8 or 10-inch pots, with that number of blooms blush pink and sweetly scented. Primula obconica, which appears to be an almost perpetual flowerer, commands attention; it should be grown in every garden, it is so useful for cutting and decoration, the trusses being thrown up well above the foliage. The dwarf Begonia weltonensis, with its pink small flowers, is very pretty, and having a prolonged flowering season becomes valuable. Fuchsias and Roses also help to make the house gay. The attractive show and decorative Pelargoniums, with endless varieties and shades of colour, are now fine. Amongst them may be noticed Duchess of Bedford, white, old, but good; Madame Thibaut, white suffused with rose, good trusses; Kingston Beauty, an old favourite; Prince of Wales, Dr. André, and Beauty of Oxtou. Zonal Pelargoniums are useful, and some of the best varieties are the following—Singles: Niphotos, white, very good; Aspasia, white pips, rounder than the former; Miss Hamilton, blush; Mrs. James Gibson, light salmon; Zelia, magenta, fine trusses; Eurydice, lilac pink, white eye; Métis, dark scarlet, white eye; Henry Jacoby, dark red, one of the best grown; International, blush, fine pips and trusses. Doubles: Circe, maroon, good; Mrs. A. Saltby, rosy pink; Pallas, salmon, flaked; Guillion Mangilli, magenta, a free flowering variety; and Wonderful, vermilion, useful and free.—F. S. W.

TRAINED CURRANT AND GOOSEBERRY BUSHES.—Where these are trained against walls or trellises the lateral growth ought to be thinned, and all shoots reserved be stopped to a length of about 6 inches. This will insure thorough ripening, and which is necessary whether the fruit is to be used early or is to be eventually matted up and kept as long as possible. Currant trees generally may also be somewhat similarly treated with advantage, but any growths required for furnishing fresh bearing wood ought to be lightly stopped only. The under side shoots on the Gooseberry bushes may be cut away now and the rest merely thinned where crowded.—M. S.

FIGS OUT OF DOORS.—Both standards and trees against walls have more abundant fruits than has been the case for many years. If all are left on the trees none will attain either their full size or quality, and thinning should at once be resorted to. The least that can be done is to remove all the fruits between the wood and the walls, or any pressing

against nails, but where very plentiful one-half of those better placed may be pulled off with advantage. It being of great importance that as much sunshine and air as possible shall reach both the fruit and next season's bearing wood, no time should be lost in thinning the young shoots. Remove all foreright shoots, and do not leave more of those better placed than are needed to thinly furnish the trees with bearing wood. Crowded, they become soft and spindly, whereas when given plenty of room the young shoots are short-jointed and firm—such only being at all hardy or fruitful. Do not take the points out of the young growth, as it is near these the fruit is formed next year. — J. M.

KITCHEN GARDEN.

THE LATEST PEAS.—Peas are common in September, but more scarce in October, and rare in November, but they might be gathered in all cases in October, and in many instances in November, if the seed was sown to produce plants that would bear at these times. As a rule the latest Peas are sown too soon, and they pod and become old before the season can be called late; but when they are secured very late they are much valued, and are always good in flavour. As early crops are cleared off plenty of space will be vacant for Peas, and a good sowing should be made now. Give them moderately rich soil and a warm sunny situation. Do not sow early varieties under the impression that they will do better than the late sorts. This is not an uncommon mistake. The late varieties are the best, and Sutton's Latest of All is a useful variety. Laxton's Omega and Ne Plus Ultra are also useful, but the latter grows too tall to suit small gardens. In the autumn it sometimes runs up to 8 feet in height, and shades everything near it. It is often a difficult matter to find stakes for it, but the other two will do with stakes 3 feet in height.

EARLY POTATOES FOR SEED.—The majority of growers save some tubers for seed, but unfortunately these are not always the best. No Potatoes are ripe yet, but often some of the smaller tubers are put aside at this season to keep for seed, and being unripe they do not answer the purpose well. We approve of saving seed, but the rows or part of rows intended to furnish tubers for this purpose should be left alone until the haulms have become brown and withered from maturity. The tubers are then firm and sound and capable of giving the best results next year. Many poor crops of Potatoes may be traced to planting badly ripened seed, and it deserves the most careful attention.

WIRE NETTING AS A SUPPORT FOR PEAS.—Many Peas are attaining unusual height this summer. Those who are trusting to secure good crops without the aid of some kind of supports will be disappointed, as when the stems fall over the pods beneath are away from the heat and light rarely fill well. Many of them fail altogether, and where stakes are not obtainable wire netting is a good substitute. It may be bought in rolls of the usual length, and in 4 feet widths. The meshes are 4 inches, and it is very strong. It will last for many years if taken in and kept under cover when not in use. The other day a correspondent informed us that it did not answer with him. He had put one row of it along the centre of his Peas and they fell away on each side, but if the netting had been placed along each side of the row and supported with sticks at intervals every branch of the Peas would have been kept in.

FRUIT FORCING.

VINES.—*Early Houses.*—*Red Spider.*—It is hardly possible in early forcing to escape attacks of red spider. More especially is this the case when the Grapes are kept for any length of time upon the Vines after being ripe. On account of the liability of Vines to attacks of red spider irrespective of the debilitation attending the consecutive yearly forcing of the Vines, we do not advise large houses with a mixed assemblage of Vines for early forcing, but structures only of such size as will admit of a supply of Grapes for the establishment or particular purpose for a period of six weeks. This admits of the foliage being afterwards cleansed with water from the syringe or engine; but with a house having Sweetwater, Frontignan, and Hamburgh Grapes ripe in May, Muscats in June, and late sorts in July, the dry air essential to the ripening of early varieties will cause red spider to increase upon the foliage of the Muscats and other late sorts before they are ripe. This is most disastrous to present and future crops of Grapes. Instead of having a mixed collection of Grapes that started in December to the new year will afford fruit from May to August, we should divide the house into two or three compartments, so that the respective varieties may have their proper treatment secured to them. In case of an attack of red spider paint the hot-water pipes with sulphur brought to the consistency of cream with skim milk, applying it thinly with a brush when the pipes are heated to near boiling point, continuing the heat in the pipes for about an hour, then allowing the pipes to go gradually cool. The sulphur fumes will destroy the red spider, and often cause brown spots upon the skin of Muscat and Frontignan Grapes; sulphur

therefore, must be applied to heated surfaces with great care and judgment. Black Grapes are not so readily affected by the sulphur as the white varieties.

Late Houses.—Late Grapes intended to hang or keep through the winter must have a final thinning, removing the smallest berries, and where too crowded allow every berry retained full space for development. Late Grapes should be more severely thinned than early and mid-season ones, leaving sufficient berries to form, symmetrical bunches having a good appearance when dished. The recent rains have been sufficient for some time, and with mulching ample nutriment will have been washed into the soil. Inside borders should be kept well supplied with rain water, previously mulching with short stable manure, but not a quantity all at once, as the ammonia arising from fresh horse manure will have a disastrous effect upon the foliage and tender skins of the Grapes. Ammonia vapour is unquestionably useful, but requires to be furnished judiciously. As the period when scalding occurs is at hand, we would repeat our advice to guard against it by increased night temperature and abundant ventilation, so as to reduce the atmospheric moisture until the critical stage is passed. After then fire heat may be economised by closing early to admit of the sun raising the temperature to 90° or 95° on fine afternoons. Regulate the young growths as required, adopting the extension rather than the restrictive system where there is room for it without crowding, keeping all gross laterals stopped so as to cause an equal flow of the sap throughout the Vines.

Young Vines.—Those of this season's planting should, provided the light is not too much obstructed, be allowed to grow unchecked, it being presumed that they will be cut back to the bottom of the trellis, or to three or four eyes at the winter pruning. Supernumeraries intended for next year's fruiting may be regularly stopped at a length of 7 or 8 feet, removing the laterals from the buds intended to give fruit next year, preserving the old leaves, and as the wood will require thorough ripening, a free circulation of air will be necessary, with fire heat if the weather be cold and wet. Vines in pots intended for fruiting next season should by this time have completed their growth, especially those required for early forcing, and may be exposed freely to light and sun to thoroughly ripen the wood and the buds.

FIGS.—Those ripening the fruit must have a circulation constantly of dry warm air, which can be secured at this time of year without resorting to artificial heat except in dull cold weather. Second crops will be advanced in size, and if the fruits are too numerous they must be thinned if the trees are expected to afford early fruits next season. Attend to stopping and tying in the shoots, guarding against overcrowding, watering the borders copiously, especially those of limited area, syringing forcibly twice a day to keep them in check.

Trees in Pots.—Do not neglect to syringe trees in pots intended for early forcing next season at least once a day, in hot weather twice, affording liquid manure at the roots, and pinching to induce fruitfulness in young plants. Stopping must be regulated by the vigour of the plants. Vigorous growers will need to be more closely pinched than those of moderate growth. Such varieties as Early Violet, Early Prolific, Black Ischia, Ciel de Perdrix, and White Marseilles are of good habit and do not require such close stopping as Angélique, Brown Turkey, and others of more vigorous habit. It is important that the trees have plenty of light, are not crowded, and are well ventilated to solidify the growth as it is made.

Figs in Unheated Houses.—The best results attend trees with the roots restricted to borders of about one-third the width of the trellis the trees are to cover; well drained and formed of good loam, with a fifth of old mortar rubbish and a sixth of road scrapings, well incorporated and made firm. Surface-mulching and watering with liquid manure will ensure fine fruits of this much neglected but delicious fruit. The trees must have unobstructed light; the nearer the shoots are to the glass, only the foliage does not touch, the better. The best variety unquestionably is Brown Turkey. Train the growths thinly and on the extension system, stopping shoots available for laying in as spurs at the fifth or sixth joint, but avoid overcrowding. Syringe well to keep down red spider, especially at closing time—i.e., in the afternoon, when the temperature is between 80° and 85°, so as to run up to 90° or more, providing a little ventilation before night, so as to allow the pent-up moisture to escape. Increase the ventilation from 75° in the morning, and keep through the day at 80° to 85°. Grand fruit will be had in August and onwards. The only precaution necessary is to afford a free circulation day and night after the fruit commences ripening, and to not supply water excessively, but afford needful supplies to keep the foliage healthy, mulching with short dry litter to prevent moisture unduly rising, and to lessen the necessity for water.

CUCUMBERS.—Repot the plants for autumn fruiting, pinching out the growing point beyond the second rough leaf of those intended for frames, and complete the preparation of the dung for affording bottom heat. Those intended for trellises should not be stopped, but trained upright, securing them to a small stick, and rubbing off the laterals as they appear to the height required to reach the trellis. Get the soil ready—good fibrous loam, with a fifth of fresh horse manure, and a fourth to a sixth of old mortar rubbish, according to the presence of grit in the loam, well incorporated, form a suitable compost. The house must be thoroughly cleansed after the old plants and soil have been removed. Although fire heat at this time of year in bright weather is unnecessary, yet in a prolonged period of damp dull weather the nights are cold, and the low temperature causes the fruits to become yellow, stunted, and curled, with canker at the collar of the plants and mildew

on the foliage. In such weather employ fire heat by night, and day also if cold. Against mildew flowers of sulphur dusted freely about the foliage is an infallible remedy, and against canker there is nothing better than rubbing the infested parts until dry with freshly slaked lime. Upon a return to bright weather after a dull period, shade from bright sun to prevent flagging, which if allowed wastes the energies of the plants, resulting in ill-shaped stunted fruits, and offers a strong inducement to red spider. In pits and frames the growths must be regularly looked over, cutting out those that are exhausted, training and earthing the plants as may be required, sprinkling the foliage at about four o'clock. In dull periods keep the beds well lined, and admit air constantly by tilting the lights a little at back. Keep the growths fairly thin, aiming at a supply of young growths to supplant the exhausted, which should be cut out, stopping one or two joints beyond the fruit. Ventilate early, just a little to allow of accumulated moisture escaping, increasing the ventilation with the increased temperature, but keeping them through the day at 80° to 85° or 90°, closing sufficiently early to insure the temperature rising to 90° or 95°. Shade only to prevent flagging. If aphides appear fumigate on two or three consecutive evenings moderately in preference to once strongly, which often seriously injures the foliage.

CHERRY HOUSE.—After the fruit is gathered the chief object is to secure the swelling or development of the buds by keeping the foliage clear of every description of insect pest, syringing abundantly, and if necessary apply an insecticide, as it is of the greatest importance that the foliage be kept clean and healthy. Although less moisture is necessary than when the fruit is swelling, yet it is necessary that there be sufficient moisture at the roots to maintain the trees in a healthy state. Trees in pots from which the fruits are gathered may be placed outdoors in the full sun, plunging the pots in ashes. Water as required to keep the soil moist, and syringe in the evening of hot days.

MELONS.—Successional plants should be earthed up as soon as the roots show at the sides of the ridges or hillocks, making the soil firm, being careful that the plants do not suffer from insufficient water, and on the other hand see that the soil is not too wet. To plants swelling their fruit supply weak liquid manure. Maintain a bottom heat of 80° to 85° for young plants, 90° with a moist atmosphere to growing crops, syringing freely except when the fruit is setting or ripening, being careful not to allow one or two fruits to take the lead, but have them all as nearly as possible of one size on a plant.

Plant without much further delay in the Melon house for producing fruit in late September or early October. Sow seed in about a week to raise plants to ripen a crop of fruit in November. In Melon houses artificial heat may now be dispensed with, except when dull cold weather prevails when the fruit is setting or ripening. Syringe growing crops freely in the afternoon at about 4 P.M. or earlier, allowing the temperature to rise, but not above 90° or 95° after closing. Afford a plentiful supply of water at the roots, when shading of the foliage will seldom be needed.

The latest plants in pits or frames will now be far advanced to setting their fruits, it being important that the fruit be set in July, or for the latest supply of fruit from frames by early August to allow time for its swelling and ripening. Give a good watering before the flowers open, line the sides of the beds with some hot dung or short grass, and leave the lights open about three-quarters of an inch constantly at the back until the fruit is set and commences swelling, then keep the growths well stopped, maintain a warm moist atmosphere by early closing with sun heat, sprinkling the foliage, and water about twice a week in bright weather or once in dull.

PEACHES AND NECTARINES.—*Succession Houses.*—With the fruit advanced towards ripening observe a course of cleanly culture. Give the border inside a thorough supply of water, and mulch with short but not rich litter. Keep the fruit with its apex up to the light, drawing the leaves aside or shortening them so as to colour it equally, but most, if anywhere, at the upper part, as it will appear that way when dished. The laterals should be well pinched, and the shoots tied in so as to keep them clear of the fruit. Ventilate freely, especially in the early part of the day, leaving a little ventilation constantly at the upper part of the house. Syringe well until the fruit commences softening, but even then damp the border in the morning and afternoon, as excessive evaporation is certain to result in red spider and thrips.

Later Houses.—The recent rains have thoroughly moistened the soil of outside borders to the drainage, and inside will be in a favourable condition for the swelling of the fruit from wet days being taken advantage of to thoroughly soak them with rain water or liquid manure. The shoots should be tied down as they advance, not crowding them, but allowing each space for the exposure of its foliage to light and air. Stop the laterals at the first joint, and to each succeeding one as made; cut back gross shoots or remove them altogether. Ventilate early and freely, and close early with plenty of moisture in the house, and admit a little air at the top before nightfall so as to allow the pent-up moisture to escape, and permit the atmosphere to gradually cool, so as to give the trees rest. Syringe forcibly twice a day, but not in dull weather, as it is necessary the foliage be fairly dry before nightfall and not kept constantly dripping with moisture. If necessary apply an insecticide, as under no circumstances must red spider, thrips, or aphides be allowed to make headway. Mulch the borders with some partially decayed manure—lumpy rather than such as when wet will form a soapy mass.

THE BEE-KEEPER.

NOTES ON BEES.

THE WEATHER.

WE have had within the past twenty years seasons with even less honey than the present one, but none approached the present one for cold and ungenial weather. No night temperature during the summer here has been above 45° Fahr. June ended and July began with a night temperature of 32°, and has been seldom much above that. We have had an almost continuous east or north or north-east wind for months, and for weeks a withering drought under a cloudless sky by day, and chilling winds with a leaden sky at night; vegetation made little or no progress. That, combined with the paucity of birds, through the eggs or fledglings being destroyed by cold, or by being robbed, allowed the caterpillars to make sad havoc with the foliage and fruit, completing the destruction that the high winds began upon the immature and tender foliage. For a week past copious rains have fallen which have had a beneficial effect on crops in general. While we have no control over the weather, we have over the birds, the husbandman's best friend, even though they do partake of a little of what they were the means of preserving.

The inclemency of the season has had a telling effect upon bees. In some districts many stocks have perished, and in most cases hives are no further advanced now than they were in the beginning of May. Swarming commenced here before the beginning of May, and others as far advanced but not swarmed are standing still. Thousands of bees are lying about chilled and dead, not so much from cold as from the chilly air, even with a temperature of 55°. Why bees can stand a low temperature of 45° at one season with impunity and fall dead at another with a much higher temperature is mysterious. The prospects of the season with bees is not altogether blasted. A favourable change has come, and ten days or so will give an abundant harvest of honey from the Clover. Strong hives, however, or doubled swarms with a short season, are the only ones to be relied upon to yield profit to the bee-keeper. Small hives are still recommended by some to be most profitable in districts having a paucity of bee flowers, but it would be quite as ridiculous to say that poor soil should not be cultivated if you expect good crops. It does not matter what the district is, the hive should be of the largest dimensions and to be full of bees at the time honey is most abundant. We have had only some six days this year that bees carried in excess of their daily wants, yet a number of my hives have their supers nearly finished, and several Stewartons with two supers on are lying out. More will be added the moment honey begins to flow, and swarms, although late, will be large, and gather more than lying out or hives bent on swarming, and two joined will excel any other system.

RAISING QUEENS.

This has been delayed through stress of weather and disappointment with stock queens bought, as Benton's first grade, which have proved themselves to be complete mongrels, while I have positive proof that the dealer who supplied these had not a single queen from Benton. We have heard much about foreign bees being unsatisfactory, and that Carniolian bees were scarcely distinguishable from the native blacks. The latter statement is misleading, because there is a great difference in the appearance and habits of the Carniolian bees from the native ones, and shows that some persons have never had experience with the true breed of that excellent and docile race of bees, while in the former case, if mongrels have been supplied instead of the pure breed, explains thoroughly the cause of failure.

At a late date, but early enough for the season, I have young queens coming forward that will be introduced in a few days to suitable stocks, which along with others will be removed at the

end of the month to the moors, where the honey from the mountain flora is finer than any produced from the plains.

As many private letters reach me regarding hives, I will at an early date give some further information as to making, working, and moving, which I hope will be instructive and remunerative to all who follow the advice of—A LANARKSHIRE BEE-KEEPER.

THE HEATHER HARVEST—GLASS SECTIONS—INVENTIONS.

A BEE-KEEPER asked in another journal for information regarding the Heather harvest, and in replying to this a writer concluded by stating that 200 sections of Heather honey from one hive could be harvested and sold at 2s. each wholesale. The sequel has just come to light. It appears in a district on the borders of Hallamshire a large number of bee-keepers attempted to carry out the instructions, tempted by the bait of £20 per hive, and went to great expense in carrying them out, with the result that at the end of the season one of them says, "A solemn company of men might have been seen accompanying their hives on their return journey" without honey in the sections, and all their hopes ruined. It is still said the 200 sections from one hive was not an exaggeration as "A Prominent Scotch Bee-keeper" succeeded in getting that amount. But this "Prominent Scotch Bee-keeper" did not report getting this amount of Heather honey from one hive. He reported over 200 lbs. for the whole season, about 60 lbs. only of which was Heather honey.

There are thousands of tons of honey annually lost on the moors for want of bees to collect it. The bees are in existence, and it would pay well to migrate them from various parts of the country if they were only in proper hives; yet the Royal Agricultural Society of England have in my opinion excluded every hive from competing at the coming Nottingham Show capable of being safely carried to the moors and back with profit. They have set up a particular type as the standard in every class, which, in my view, is a wrong one for migratory purposes.

Some time ago "Felix" tried to contend "that it was of no practical importance to bee-keepers who discovered or invented the different things in use, so long as they had the use of them," but subsequently said he should honour or thank those who had directed him right as soon as he had tested the matter.

I have been for eight years studying out something which, when published and understood by the public, will revolutionise the present mode of bee culture. One part is to make sections wholly of glass—waste pieces from the glass warehouses called "cullets," to be had for 2s. 6d. per cwt. A hundredweight will make 500 pound sections, and an ordinary girl, with tools costing only 2s., can cut them up into sizes which can be made into true, rigid, rectangular sections, with foundation fixed, much quicker than the wooden one-piece section can. Now shall I explain the whole thing, and run the risk of being deprived of the credit of my inventions; or what shall I do?—A HALLAMSHIRE BEE-KEEPER.

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Grubs in Soil (Thomas O.).—The contents of the boxes shall be examined and a reply given after the investigation. We are now preparing for press.

Wiring Walls (W. B.).—Your letter shall have attention; it cannot be satisfactorily answered this week, as our pages are almost ready for printing.

Jones' Terminal Saddle Boiler (W. Lambourn).—We are unable to answer your question relative to this particular boiler, but terminal saddle boilers are included in the illustrated catalogue of the Thames Bank Iron Company, Upper Ground Street, London, S.E.

Gas Tar and Fruit Trees (J. S. O.).—Painting the stems with gas tar is the cause of deaths among your Apple trees, and of injury to the Pear trees. It is violently poisonous to them, and the poisonous constituent probably is the creosote.

Thinning Grapes (A.).—Cut off one of the bunches from each shoot without any reservation. If one bunch is smaller than its fellow, cut off the smaller. If they are of equal size cut off that one which is furthest from the stem.

Tomatoes Diseased (F. W.).—We are just going to press. Cut off the diseased leaves and burn them; dust with sulphur; maintain a dry breezy atmosphere; use less stimulants. Some affected specimens have been sent to the Scientific Committee of the Royal Horticultural Society, and will probably be referred to in the report of the meeting.

Change in Establishment (J. G.).—We are very sorry to hear of the change and accord our sympathy, but under the circumstances think you cannot do better than make the best of the position, retaining your footing where you are till something better presents itself for your acceptance.

Gesnerias (J. E.).—*Gesneria cinnabarina* grows about 18 inches high, and the others you name are similar in height and habit. They are very beautiful when well grown, especially for flowering in a stove in the winter. Tubers can be procured from nurserymen, but so far as we know seed is not procurable.

Dipladenias (J. Gibson).—Your seedlings are worth preserving, though we have seen some similar to them, we think at Chatsworth. When you have good flowering plants ready, not necessarily large, you might send them to one of the meetings of the Royal Horticultural Society for examination by the Floral Committee.

Ivy Eaten by Cows (Constant Reader).—Ivy is not injurious to the health of cows, at least we have not known any mishap to arise from their eating it, and we have noticed it to prevail largely in hedgerows, on trees, and in woods to which cows have free access without their being in any way prejudiced. We cannot name Roses or other florists' flowers, as is stated below.

Red Spider on Cucumbers (Cambridge).—If on a trellis and the under sides of the leaves are frequently and forcibly syringed, the enemy can be so kept in check as to do little injury. After a few good drenchings mix some sulphur in the water, forming a cream that can be applied with a syringe, allowing the sulphur to remain on the leaves for a few days, shading in very hot weather, then repeat the drenching.

Manure for Azaleas (Anxious).—Chemical manure may safely be given to plants that are in need of support, but it is not advisable to continue furnishing it after the buds are set to plants that are vigorous, as it has a tendency to induce growth to push from the base of the buds and so interfere with their flowering satisfactorily. Applied to weakly plants it would assist them to swell the buds and retain the foliage, but it would be more injurious than beneficial applied to plants at this season.

Comparing Vegetables (Philomel).—When a very large collection of any kind of vegetable is grown, practically including all recognised varieties, it is surely not a difficult task to compare one with the other, or others that may be sent with either, and so determine the distinctness or dissimilarity of varieties in the most practical way. This has no connection with fruit, and there is no parallel between the cases cited, the principle involved being entirely different. If you strike out the word "new," which was obviously an accidental insertion, much of the difficulty you experience will be removed.

Cabbage and Onion for Early Use (J. M.).—One of the best Cabbages to sow about the middle of this month for spring use, according to our experience, is Ellam's Dwarf Early Spring. The Queen Onion is remarkable for the rapidity of its growth, which ripens before larger sorts. It, however, is a small Onion of symmetrical form and small top. Early White Naples is larger, of quick growth and mild flavour, a fine sort for autumn sowing, which should be about August 10th. 2. There is no work on the subject you name. The cultivation of Strawberries under glass has been fully treated of from time to time in our pages, and is repeatedly alluded to in "Work for the Week."

Garden Produce (J. N. J.).—As a rule it is not profitable to send small quantities of vegetables to Covent Garden salesmen. As you are within easy reach of London you had better pay a visit to some of the salesmen and explain to them the nature and quantity of the produce at disposal. You will then see for yourself the sizes of bunches of vegetables now, for they vary greatly, according to the size of the individual articles of which they are composed, and the season. It is not possible to give precise information on the subject that would be of avail for market purposes, and knowledge gained by personal inspection is highly desirable, if not imperative.

Budding Roses (Kittie).—Your own successful experience shows that Rose buds placed for a moment in the mouth of the operator, as a matter of convenience, has no ill effect. Countless thousands have been so moistened and afterwards "taken" well. It is not customary to shorten the stems of Briars when the budding is done, as a free unobstructed flow of sap is desirable, and shortening the shoots is calculated to give a temporary check at a critical time. We know quite well that

instances of success can be cited when the shoots have been cut back when buds were inserted, and it is certainly not necessary to place them in the mouth if they are not allowed to get unduly dry out of it; but the rule is as stated.

Fruit Growing and Bee-keeping (D. D.).—A gardener of great experience in Scotland who has been consulted on the subject of your letter sends the following reply:—"Glasgow is supplied almost exclusively from the Edinburgh district and the south. Fruit is somewhat extensively cultivated in the Lanark, Hamilton, and other districts, but these mostly by field culture. Rothesay or Dumbarton might be tried for a small piece of ground. Rents are low there, but exact figures cannot be stated, as the price varies according to the land and size of plots. Mid or East Lothian is the most suitable district, but there is great difficulty in getting ground, which moreover lets high, twenty to thirty miles from Edinburgh at from £5 to £12 per acre. The only method of learning would be to get employment with a good grower. Local inquiry would let your correspondent know more than it is possible to state here; but unless he wishes to cover his ground with glass two or three acres will not be sufficient to make a living out of as things go at present." With this last observation we fully agree, and also concur in the advice to seek information in the districts alluded to.

Sowing Ferns (F. S.).—Several of the finest Ferns cannot be increased by division; or, if they can, several years elapse. If right means are followed, they may be raised from spores. This requires a constantly humid warm atmosphere, and little, if any, sunshine. Procure a wide earthen pan, a hand or bell-glass that will go within it and rest on the bottom, and a shallow wide pot that will stand within the glass and above the rim of the pan 2 inches or 3 inches. Fill this pot half full of potsherds, and upon them a sufficient number of small pieces of turfy peat, mixed with small pieces of sandstone, about the size of peas, to come up to the pot. Then take the frond of any Fern that is full of spores or seeds, and with the hand, brush them off upon the prepared pot, set it in the pan, place the glass over the pot, and fill the pan nearly with water. Place the whole in the warmest part of the stove, shading it from the sun. The small pieces of turf and stone can be easily separated, and the seedlings on each put into small pots, without any danger of destroying them by the process of potting. In the moist atmosphere of the Orchid house several species of Fern will come up spontaneously in the pots, baskets, and upon the blocks. These may be carefully detached as soon as they are large enough, and potted in small pots, placed for a time in a shady situation, and they will soon make nice bushy plants. Ferns require a light open soil. A compost of sandy fibrous peat two parts, turfy loam one part, and leaf mould one part, with a free admixture of sand, will suit them well.

Peach and Nectarine Shoots Gummied (E. H.).—Gum occurs most frequently and is greatly encouraged, if not induced, by too rich soil, over-manuring, or too liberal supplies of liquid manure. It is a consequence of over-luxuriance, a flow of crude sap disproportionate to the power of elaboration and assimilation. It may be caused practically by a check to the circulation of the sap consequent on disbudding, or a dull cold period in the early stages of growth when the sap is torpid, followed by a warm moist one favourable to rapid growth without the corresponding increased power of assimilation—conditions productive of tissue favourable to the fungus, *Coryneum Beijerinckii*; indeed it is questionable if the disease attack other than trees with imperfectly assimilated sap. Plowright states that "the fungus cannot penetrate the bark, abrasion or laceration being necessary before the germ tubes can enter." Hence the predisposing causes require careful consideration, and unless over-luxuriance, the sap being in excess of the power of assimilation by the foliage, young wood, and fruit, the reciprocal action of the roots with the head being discontinued, fungus, or its resulting gumming, does not occur. Lifting the trees and laying the roots nearer the surface in firm soil containing less organic and more inorganic matter is the only certain remedy. It is a good plan, however, to cut away the affected parts and burn them, and by stopping or removing gross growths, seeking an equal distribution of the sap or equality of vigour throughout the trees, with full exposure of the foliage to light and air, so as to insure thorough solidification of the growth. Sturdy short-jointed wood, thoroughly matured, is the chief object to attain, and this secured, gumming will not appear.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*A Young Hand*).—As has been dozens of times indicated, it is essential to know the character of the flowers, small or large, for naming Peaches and Nectarines; fresh and good leaves are also necessary, those sent round the fruit being inadequate.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*H. A.*)—1, *Acerides crassifolium*; 2, *Dendrobium chrysanthum*. (*G. W. C.*)—It is an excellent variety of *Phalenopsis speciosa*; the other plant is *Rodriguezia planifolia*. (*J. C. H.*)—1, *Spiraea Aruncus*; 2, *Astrantia major*; 3, *Asphodelus luteus*; 4, specimen too much withered; 5, *Iris siberica*. (*S. T. R.*)—1, *Russelia juncea*; 2, *Gypso-*

phila paniculata. (*J. J.*)—1, *Dendrobium chrysanthum*; 2, *Lilium Martagon*; 3, *Veronica teucrium latifolia*; 4, *Campanula glomerata*; 5, *Thalictrum aquilegifolium*. (*Herefordian*).—*Lælia purpurata*.

AGRICULTURAL EXPERIMENTS.

WITHIN the last few days we have received reports of agricultural experiments now being made by Professor Jamieson in Sussex, by Dr. Voeleker and Mr. Carruthers at Woburn, by Mr. Martin J. Sutton at Dyson's Wood, by Sir John B. Lawes at Rothamstead, by Sir Thomas Acland at Killerton, and by the Manchester, Liverpool, and North Lancashire Agricultural Society at Saltney and Rostherne. Glad indeed are we to see in the last-named report that at Rostherne Lord Egerton is using a mixture of nitrogenous and mineral manures at the rate of 3 cwt. per acre, consisting of quarter cwt. nitrate of potash, 1 cwt. nitrate of soda.

quarter cwt. steamed bones, and $1\frac{1}{2}$ cwt. superphosphate. This is clearly a step in the right direction, but it will be found advantageous to use muriate of potash instead of the expensive nitrate, and to use twice the quantity if the Clovers are weak.

As a practical outcome of all these experiments we hope soon to hear of real work far beyond the scope of mere trial plots. Often have we told our readers how we put chemical manures, farmyard manure, and sheep-folling fully to the test upon grass land laid in for hay, and in reclaiming poor pasture. We thus proved that sheep-folding and well chosen chemical manures were alike profitable, and that farmyard manure was comparatively unprofitable.

The matter has long ago passed from the vexatious vagueness of mere opinion to the safe ground of positive fact, yet we still find the advocates of muck proclaiming it as being altogether superior to artificial manure. So it is undoubtedly superior to much of the rubbish which has been foisted upon farmers in the guise of special mixtures for special crops by plausible dealers. What we want farmers now to see in their own interest, what the experiments are intended to make clear, is the important fact that pure chemical manures can, by the aid of science, be made to store the soil with plant food as fully, and far more economically, than ever can be done with the very best farmyard manure. But there are serious obstacles in the way of the diffusion of such knowledge. Long-established custom, combined with ignorance and prejudice, are only to be overcome by the tangible proof of profitable results, and until reports of experiments take a more positive tone very little good is likely to be done by them. The North Lancashire Report justly observes that it is tedious to arrive at the truth, especially in agricultural matters. With equal justice Mr. Martin J. Sutton said at Dyson's Wood that the results of his experiments were hardly applicable to the country at large.

What is wanted now is for private enterprise to apply what knowledge has been gained by the experiments, and we are glad to know that this is being done more extensively than is generally supposed. We only hope to hear much more than we have done of results. In Sussex, Major Sergison has done good work in the manner desired, notably in Wheat culture. Seven years ago he took over from a tenant some land pretty well farmed out; by thorough cultivation and the use of pure chemical manures he obtained a fair crop of Wheat the first season. It was, in point of fact, so good that he mentioned it at a local agricultural show dinner, and in response to the challenge that he could not do it again, he has continued growing Wheat upon the same field ever since, applying Professor Jamieson's mixture, or rather chemical manures mixed at the farm according to his formula, and now he is able to show a better crop of Wheat than he had at first. This is quite in accordance with our own experience, and we may here notify our intention to sow Wheat and Barley upon the same land at each of our farms every year. It is a notable fact that there is frequently a wide difference in the soil of a farm. For example, we have a heavy land farm with some 40 or 50 acres of excellent mixed soil, admirably adapted for Barley. We have a flourishing crop of Barley upon that part of the farm this year, and have told the bailiff to devote that land constantly to the same crop, just as he is to continue growing Wheat and Beans upon the heavier land. Now, when we took over this farm we found the Barley land just laid down to permanent pasture, while the poor heavy land was under corn, and we had to reverse this order, or rather disorder of things—to lay down the land which did not answer to keep under the plough, and break up that which did. To grow two white straw crops in succession upon the same land, to sell straw off the farm, to continue cropping without a long fallow, to use artificial manures instead of muck, was generally condemned at one time, and is considered not only wrong but ruinous by farmers of the old school. All this, however, will come right, only "it is tedious to arrive at the truth," and when we have it is still more tedious to induce others to believe.

WORK ON THE HOME FARM.

Haymaking is now in full swing, and we long for a change to settled weather, as otherwise the work will prove both tedious and expensive. So far we have kept the mowing machines at work even in showery weather, for the grass sustains no harm for a few days after it is mown if left unturned, and by keeping the tedding machines briskly at work in fine weather, and following with the horse rakes and putting the hay into cocks good hay can be made. We could not well wait longer, for the early grasses were in seed, some of them approaching ripeness, but the showery weather induced so strong a growth in the late grasses that by the exercise of watchfulness and care we hope to have good hay. On the whole the crop is certainly more abundant than it was last year, yet generally there has been such a scarcity of sheep feed that both pasture and layers have been fed off closely, and hay should be dear next winter. But this is by no means certain. If Maize and Oats continue so low in price, they tend to keep down hay; at any rate, it was so last winter. We shall have one or two air shafts in each large hayrick, as fermentation is apt to be excessive in showery weather, and the rick cloths will be drawn up off the hay as early in the morning as the weather admits of.

The growth of Clovers and Grasses is an interesting study at this season of the year. No doubt the finer Grasses impart a tempting appearance to hay, but for bulk of crop combined with quality we certainly are bound to give preference to Cocksfoot, Rye Grass, and other Grasses of exceptionally robust growth. There is such a thing as over-refinement in permanent pasture, especially upon poor land. We like big hayricks, and under good cultivation such Grasses as we mention go far to ensure them. If the hay is coarse in texture it is palatable enough, and if sheep or horses will not eat in one form they will in another. Certainly such hay compares favourably with that from many an old pasture, where the herbage often consists of indigenous Grasses, and is very poor in quality. For temporary layers of three or four years' duration very heavy crops of most excellent fodder are had by the judicious sowing of strong-growing Grasses and Clovers.

OUR LETTER BOX.

Treatment of Cows Before Calving (A. B.).—You appear to share the common but erroneous opinion that a pregnant cow should be in condition. On the contrary, it should rather be in as full lusty a condition as is possible short of fatness, for not only has it to supply nourishment to the calf before birth, but also to yield a full flow of milk after calving. Certainly a full dietary of good grass now, for a cow expected to calve at the end of the present month, is highly desirable. Here are a few simple rules for your guidance:—Let milking cease entirely six weeks before calving. Manage this by milking once a day for a while, and then once in two days. If this is done with care all risk of a loss of quarters is avoided. Avoid systems of semi-starvation, by which cows are rendered weak and low in condition at the time of calving. Rather let them have more sustenance, in order that they may produce a fine calf, and a full rich yield of milk subsequently. Do not, however, change suddenly from a low to a high diet or you may induce milk fever. It is unnecessary to interfere in ordinary cases of calving; it is only in protracted labour or false presentations that help is required in the manner mentioned by you. After the calving give the cow a warm—not hot—mash, and let the drinking water be slightly warm. A few hours after calving a pound of Epsom salts and two drachms of ginger may be given as a safety drink. Inflammation of the udder may generally be prevented by allowing the calf to remain with the cow and suck when it pleases. In all cases of danger or difficulty a veterinary surgeon should at once be called in.

REMARKS.

- 1st.—Generally fine, but not much sun.
- 2nd.—Rain nearly a 1 day; short dry interval about 6 P.M.
- 3rd.—Snowy, especially in the afternoon; much wind.
- 4th.—Fair morning; shower with distant thunder at 1.30 P.M.; thundery again, with slight rain, from 2.15 P.M. to 3 P.M., otherwise fine and bright, with spots of rain about 5 P.M.
- 5th.—Bright early; heavy rain from 10.30 A.M. to noon, and from 2.50 P.M. to 3.10 P.M. frequent showers and thunder in afternoon and evening with occasional lightning.
- 6th.—Overcast all day, with heavy rain from 11 A.M. to 11.30 A.M.
- 7th.—Dull, with occasional slight showers or drizzle.

Overcast rainy week, with low maximum temperatures.—G. J. SYMONS.

THE SEASON SO FAR.

IT is late, very late, and at the moment of writing the prospect is by no means exhilarating. A protracted winter retarded the blossoming of fruit trees, and as a consequence a golden harvest was expected in the autumn. But the blossom did not entirely escape injury by frost, and the fruit that set did not swell kindly. Much has vanished; and though some trees are laden here and there, many are barren, or nearly so, though why this should be so is perhaps in some cases a little mysterious. Some of the heaviest laden Apple trees we have seen are at Chiswick—trees grafted on Paradise stocks about ten years ago, and now forming a plantation, with just room enough for passing between the rows. Cox's Orange Pippin, Duchess of Oldenburg, Stirling Castle, Small's Admirable, Braddick's Nonpareil, Lane's Prince Albert, and a few others are wreathed with fruit; but that usually free-bearing Apple, Cellini, has failed with a curious exception. There is a row of it, embracing several trees, but on the majority of them scarcely an Apple is to be seen, though two trees in this row are almost overweighted. How is this? Can Mr. Barron tell us? If he cannot no one can, and the circumstance must be regarded as a pomological puzzle.

The season, so far, has been remarkable for cold and caterpillars. These latter have hung in festoons on thousands of trees in the vicinity of the metropolis, ruining the hoped-for crops of fruit, for either the blossoms or the leaves, or both, were devoured. The Small Ermine and Winter Moths are increasing near towns. Why is this? Is it not to a large extent due to the absence of birds from the localities where their natural enemies—men, boys, and cats—are the most numerous? The greater the number of these in a given area, the less in number the birds must of necessity be, and, correlatively, the greater the increase of insects of various kinds. The world we live in is a delightful world without a doubt, full of wonders and of beauty; but all the same it is a savage world, the strong devouring the weak continually. If the birds are destroyed or driven away insects increase, and as these multiply vegetation suffers. If by artificial means, and the assumed necessities of life, the balance of Nature is destroyed, man must pay the penalty, because it is by his action that the deed is done. The impelling forces may be too powerful to resist in certain localities, as where town growth is as persistent as tree growth; but in rural districts is the economy of bird life sufficiently appreciated? As birds decrease caterpillars must increase, and there have been far too many of these; not near towns only, but in "Nature's solitudes" during the present year. Caterpillars have their parasites no doubt, but these appear inadequate for keeping the destructive horde of blossom and leaf-eaters within reasonable limits. The whole subject appears to be worth thinking about, and having introduced it we pass from the caterpillars to the cold.

At a flower show in Kent last week three of the judges were working in overcoats, and the fourth was shivering because he had been so thoughtless as to go out without one. It was the 11th of July, and he ought to have known better. But perhaps the judges were tender, some may imagine. Those who have the pleasure of being acquainted with Mr. John Fraser of Lea Bridge, Mr. John Laing of Forest Hill, and Mr. Ward of Leytonstone, will not regard them as tender exotics, but rather as being as hardy as Highlanders. Well, those were the judges working in overcoats

on July 11th, 1888. The date is worth recording, as the day will not be forgotten in various districts of the country. As to the venturesome fourth man who left his outer garment at home, he suffered enough without being made to endure more by "naming" him, as they say in Parliament, when a member does something amiss.

Cold, however, as the day was in Kent it was colder elsewhere. Snow in the north, in places to the depth of 6 inches; snow in the midlands, hail in Surrey, and the thermometer registering within 4° of freezing at Heckfield in Hampshire. That is the record. A daily paper gives a concise digest of the "summer" weather:—

"The unseasonable weather recently experienced over England must surely have reached its culminating point. At eight o'clock in the morning of the day named the thermometer stood no higher than 44°, or considerably lower than any July reading on record for that particular hour of the day. Later in the day in London it rose to a maximum of 54°, a very respectable reading for a February afternoon, but a miserable level for July. The vicissitudes to which our climate occasionally exposes us have seldom been more strikingly exemplified than in the tremendous contrast which has existed between our recent weather and that of last summer. Comparing the meteorological records for the two seasons we find in the first place that the mean temperature of the past five weeks over England has been from 5° to 7° lower this year than it was during a similar period in 1887. Last year there were in London eighteen days in the course of the five weeks with a maximum temperature exceeding 75°, ten days with a maximum of over 80°, and two with a reading of over 85°. This year we have had during the same period only two days with a temperature above 75°, only one with a reading exceeding 80°, and none reaching 85°. The records of bright sunshine tell a still more remarkable tale, the aggregate amount of this very desirable element recorded during the present summer being less than half the amount registered last year. In our midland and southern districts, including London, the sunshine experienced during the past five weeks has not amounted to more than one-quarter of the possible quantity. Last year in the metropolis we had 53 per cent. of the possible amount, while in the midland counties they had 53 per cent., and in the eastern districts as much as 61 per cent. In the matter of rainfall the contrast between the two seasons has, of course, been exceedingly marked. During the early part of last summer a severe drought prevailed over the kingdom, and in the five-week period under review the total amount of rain experienced in London and over the home counties generally was less than a quarter of an inch. This year we have had in the same localities from 4 to 5 inches. Last season rain fell in London on three only out of the thirty-five days; this year it has fallen on as many as twenty-four."

That is a serious statement. It puts the weather prophets out of court, at least those of them who predicted a hot dry summer, one of the tropical "cycle" which had set in. The effects of the cold and wet are apparent. Rosarians are disappointed. Strawberry growers have entertained great loss. Hop growers are despondent. Farmers are grieving over the loss of hay and trembling in fear of a bad harvest. Gardeners are inconvenienced by the failure or lateness of fruit and the weeds that almost overwhelm them. Gardens and fields are green, too green, and even the root crops want heat for inciting free growth and early maturity, and if the rains do not cease soon the old enemy, the Potato disease, may again assert itself. As a rule late crops mean loss. There may be exceptions, but early harvests prove the rule, for they are almost invariably good while late ones are the reverse. It is much the same with garden crops, their value being usually in proportion to their earliness, though there are exceptions—in, for instance, late Grapes and Broccoli. But these are special. Cultivators cannot in a season like this have the crops ready for use at the usual time; but those who habitually start

early have the advantage over their brethren who are generally behindhand with their work. Some of them may be helpless to avoid this, while others may not be quick to see what must be done at a given time and what may wait; then follows hesitation, and there are moments when the "man who hesitates is lost." We can only hope now that the winter is at last over and that summer may yet come and terminate in a brilliant autumn.

PRIZE GROUPS.

THE tasteful arrangement of plants is a portion of a gardener's duties now much in request, for never have plants been so extensively and generally employed for decorative purposes as within the past ten years. The classes provided at the principal horticultural shows throughout the country for groups have no doubt tended largely to the improvement of taste in these matters, not only amongst exhibitors, but amongst the more numerous gardening visitors who do not compete publicly, yet have much home work of a similar character requiring their attention. At one exhibition near London, *i.e.*, that held by the Chiswick Horticultural Society, the groups have for several years been an important feature, and recognising this a generous supporter of the Society, Mrs. S. A. Lee, determined last year to give still further encouragement to exhibitors. This took the form of a Jubilee challenge cup, value twenty-six guineas, offered with the condition that it "became the absolute property of the exhibitor who is awarded the first prize three years, not necessarily in succession." The group to be arranged for effect in a space not exceeding 100 square feet. Money prizes, consisting of £4, £3, £2, and £1, were also contributed by the Society, and although there were only three competitors at the 1887 Show, and the same number at that held last Thursday, the style of their arrangement and their general excellence were distinctly in advance of what are ordinarily seen at shows. It will be remembered that last year Mr. W. Brown, St. Mary's Grove Nursery, Richmond, was the winner of the first prize, and his group, an exceptionally beautiful one, was illustrated in this Journal, page 75, July 28th. This season he repeated his former success in winning the premier prize, but surpassed his previous efforts in graceful arrangement. The winning group was critically examined by a number of horticulturists, and only one opinion was expressed even by the other defeated but generous competitors—namely, that it was faultless. Of hundreds of such groups, staged in all parts of the country, I have never seen one so admirably finished, so light and so bright without a preponderance of colour or the introduction of discordant tints. It bore the impress of a keen and accurate study, combined with excellent taste, so that the art employed was most carefully concealed, and the effect natural and pleasing in the extreme. No unsightly pots or bare ugly stems visible, not a suspicion of crowding nor yet of thinness, all the plants well chosen, and an admirably finished margin. It was, in fact, a surprise even to the exhibitor's closest friends, and amply deserved what was freely accorded—the highest praise.

A few details respecting the plants employed may be given, but it is difficult to convey an accurate idea of their combination and the many points which made the group remarkable. The taller plants in the background were light graceful Palms, *Cocos Weddelliana*, *Kentias*, &c.; the chief other foliage plants, *Caladium argyrites*, a few well-coloured *Crotons*, clearly variegated *Cyperus alternifolius* and *Eulalias*, with a groundwork of *Adiantum cuneatum*. One characteristic of the Ferns, and it added much to the beauty of the group, was their fresh bright green colour; owing to the number of young well-developed fronds with which they were furnished, and it was surprising what an influence this had on the general effect, the soft green of young *Adiantum* fronds being a particularly pleasing yet almost neutral tint. The flowering plants were *Lilium lancifolium* varieties, *L. longiflorum*, *L. auratum*, and *L. candidum*, only a few of each, two or three richly coloured *Cattleyas* peeping out near velvety *Gloxinias* and delicate *Odontoglossums*, a small graceful yellow-flowered *Oncidium* in the centre near a deep red narrow-leaved *Croton* having a charming appearance. In the background, partially concealed by the *Eulalias* and other foliage plants, were some brilliant *Kalosanthes*, which in a more prominent position would have "killed" all other colours, but placed as they were they afforded a kind of subdued light, imparting life and warmth to the group. Very few *Crotons* were employed, medium-sized plants well-coloured and furnished with foliage to the pots, one of the red-veined majestic type in the centre, two of the graceful drooping golden *interruptus aureus* type at the sides, and two *Disraeli* varieties towards the front. The margin also was carefully considered, very fresh *Adiantums*, the silvery and red-veined *Fittonias*, and *Caladium argyrites* being the

plants associated together in a free natural manner, and all pots concealed.

The two other groups were commendable in no ordinary degree. That from Messrs. Hooper & Co. was but few points behind the first, but two or three slight mistakes were noticeable. First, slightly too many plants were employed; secondly, a dark *Anthurium* was placed in the background, which had precisely the opposite effect to what was needed on so dull a day; and thirdly, the margin was partially of dark moss and partially of *Selaginella*. A point would be lost on each of these defects, but beyond that it was equal to the other in style, arrangement, and harmony, for Mr. Bruckhaus is one of the most experienced and successful competitors in such classes. Mr. Fromow's had all the merits of lightness and grace, but was slightly wanting in finish, while in another class Mr. Hudson's silver medal group afforded ample evidence of good taste. Altogether there is no question that such groups are not only useful and educational, but they also afford an interesting feature to visitors.—L. CASTLE.

STRAWBERRIES FOR FORCING.

SINGLE CROWNS.

THAT plants restricted to one crown are better for forcing than those allowed to form a number of crowns cannot be substantiated. It is a theory that has originated undoubtedly by making no provision for early runners, thus half the season has gone before the plants have been started, leaving insufficient time to thoroughly develop one good crown. When the plants have been allowed a natural course they have developed minor crowns, which have told against the principal one, and being insufficiently matured to flower have only crowded the plants with foliage, hence those with more than one crown have been condemned for forcing purposes. If notions of this nature become firmly established they are difficult to eradicate.

The single crown theory has led to evils, and crown-splitting is one result. It is unnatural for many varieties to be restricted to a single crown. Take Sir Joseph Paxton and Vicomtesse Hericart de Thury for example. Long before they have developed a strong crown or produced others, attempt to restrict these to one crown, and the result, if layered, say before the close of July, and with an average season, is that a large per-centage will split their crowns in the last stages. President may be taken as an example of those that naturally develop one strong crown instead of three or more. Crown-splitting with varieties of this type is more liable to take place under any system of culture than those that increase their crowns naturally in the early stages of their growth. Splitting nearly always takes place near the end of the season when the plants have developed their main crown. This seldom occurs when they have other channels in which to direct their energies, but when restricted nothing but a divided crown can be anticipated.

When the plants are layered early, say by the end of June, the crowns will be fully developed while the weather is good and the sun has still power. A divided crown is not then such an objectionable feature as many would lead us to believe. A plant that has split its crown just before early frosts is certainly unfortunate, but when it takes place in time for both crowns to be further developed and thoroughly matured, it is capable of producing more large fruits than a single crown. If layers are taken early and allowed a natural course no one need trouble about crown-splitting.

A friend writing a week or two ago said, "I know your plan of raising plants and retaining a plantation purposely for runners is an excellent one, but many situated as I am have not the room or time to attend to them." I know exactly how my friend is placed, but very little room is wasted by carrying out the plan on the lines I have advised. For example, let us look at the border which is producing runners this season. The Strawberries were planted after a crop of early Potatoes (*Myatt's Prolific*) without manuring or digging the ground, the rows being 18 inches apart and the plants 1 foot asunder in the rows. Between the rows a late crop of Cos Lettuces was taken. Another crop of Cos Lettuces has been taken from the border this season. The available space between the rows is now filled with 5, 5½, and 6-inch pots, with the runners pegged into them. There is no method known to me that requires less labour than layering direct into the largest pots. Layering into small pots with watering and potting will take double the time. A smart man in a day of ten and a half hours will fill with soil 1000 5 or 6-inch pots, provided the pots are crocked, the soil ready, and placed on the bench. But to return to the plantation. When one is planted every season for yielding early runners it is in the best possible condition for bearing a heavy crop of fine fruit the following one, and this leaves a plantation to be destroyed after the fruit has been gathered, and from the

ground a valuable winter or spring crop can be taken. Very little, if anything, is lost by this close system of cropping.

I intended referring especially to the system described by Mr. R. Inglis in August last. It deserves more attention than has been bestowed upon it. I promised to try it, and have done so, and in spite of the objections that can be urged against it the plan is an excellent one. I strongly advise all who are short-handed and sadly limited for room to give it a trial, for it is perhaps the best of all methods for small growers and those similarly situated. I am not certain whether it will not commend itself to those who grow on a large scale, especially for all the plants required for forcing moderately early in the season. The substance of Mr. Inglis's plan may with advantage be given again. After the Strawberries have fruited and the plantation has been cleared of weeds, litter, and runners, the ground is hoed, and the plants produce a late crop of runners. When these are rooted, which is the case by October, they are taken off and dibbled into the ground 2 inches apart. In spring they are placed in small pots directly signs of growth are visible, and the pots are plunged in ashes, the final potting taking place during June and the early part of July. One grower having tried it, objected to the system because it had the disadvantage of causing the "crowns to split." This objection is not worth consideration if the plants are left alone after their final potting. Mr. Inglis tried, if I remember rightly, to point out that to guard against this evil the crowns were thinned. Unless I have observed wrongly this method of treatment is just the course to follow if the grower wishes the plants to divide their crowns. If they are to be thinned let it be done after the completion of growth, and then only the puny crowns that it is certain will not flower. I also raised objections to the system, but principally from an economical point of view, the plants being too long on hand, and therefore entailing more labour than is occasioned by providing a plantation and layering direct into the fruiting pots. I must still maintain this objection, for the labour required is about the same as when runners are pegged first into 60's and afterwards placed in their fruiting pots. They are liable also to be seriously stunted by following closely the original plan.

In spite of these objections, some of which can be overcome, this system, or one that has sprung out of it, is well worthy of consideration. To give some idea of the estimation I have of the method, I shall prepare 1000 plants of *Vicomtesse Hericart de Thury* for early work in pots next year. When selecting small runners for the formation of a new plantation the required number will be potted. When rooted they will be planted out 6 inches apart in some position where they can be watered at night prior to lifting the next day if the ground is dry. This allows of their being placed direct into the large pots in June. Why we pot them previous to planting at first is only a natural question. I have varied Mr. Inglis's plan by potting and by retaining plants in small pots, and like the potting and planting out better than dibbling them out or retaining them in pots. By the last method small pots become too crowded with roots for the well-being of the plants. Those dibbled out cannot on our light soil be lifted satisfactorily, and are therefore seriously checked while they are in full growth. Those potted can be lifted readily. A good watering is given after they are potted, they are well syringed twice during the day, and in ten days they are rooting again freely and growing vigorously.—
WM. BARDNEY.

THE GARDENERS' ORPHAN FUND.

WHEN propositions were made about seventeen months ago, which culminated in the establishment of this charity on July 12th, 1887, the most sanguine of its promoters could scarcely anticipate that so much would be done in so short a time as has actually been accomplished. The decision arrived at by the Executive Committee at the first annual meeting described below must come as a gratifying surprise to the majority of persons who have followed the progress that has been from time to time recorded of the young but vigorous organisation. As is stated in the official "Report," "the fact that expenses have been met and provision made for electing six children the first year, is, if not unprecedented, certainly most gratifying." But the Committee has gone even beyond its own report in having unanimously determined at the last moment not to exclude any candidates whose claims were admitted from the benefits of the Fund. The step taken was a bold and generous one, based on a trust in gardeners and those whom they serve to increase their efforts in obtaining support for an institution that is destined to gladden the hearts of widows, and afford the means of sustenance to the children of gardeners left practically helpless on the world. The Gardeners' Orphan Fund has made a splendid beginning in its work, and it is most gratifying to know that other excellent institutions with which gardeners are identified have gathered strength since this was established. The

anniversary dinner and "great gathering of gardeners" equalled, if it did not surpass, all that was expected of it by the promoters. A noble room, splendidly decorated with towering Palms and various plants; seven long tables most tastefully furnished with flowers and fruit; music provided by talented artistes; the finest representative company of horticulturists seen for many a day; excellent and high-toned speeches; viands choice and abundant—all these combined to impel experienced "diners out" to express the opinion that it was "the best and most successful 5s. dinner ever held in London." The manager of the Cannon Street Hotel deserves a word of warm congratulation, while all who contributed plants, flowers, and fruit merited the thanks that were unanimously accorded by the assemblage. The various speakers were much applauded, and bouquets were presented to Miss Mary Belval and her accomplished coadjutors, who contributed so much to the evening's enjoyment. The proceedings of the meeting, with a condensed report of the after-dinner speeches, are appended.

ANNUAL MEETING AND ELECTION.

THE general annual meeting of the Committee and subscribers was held in Cannon Street Hotel on Friday, the 13th inst., at 2 P.M., Mr. G. Deal in the chair, but there was only a small attendance, as the majority had sent in their voting papers and did not arrive until a later period for the dinner. The Hon. Secretary, Mr. A. F. Barron, read the advertisement calling the meeting, and then also read the annual report and balance-sheet which follow.

REPORT OF THE EXECUTIVE COMMITTEE, FOR THE YEAR ENDING JUNE 30TH, 1888.

The first duty of the Executive Committee of the Gardeners' Orphan Fund is to record a feeling of gratitude for the support that has been accorded, and which has placed the charity on a basis firmer and sounder than could have been reasonably anticipated when the propositions were made that led to its establishment.

In this, the first annual report, the Committee think it desirable to recount briefly the origin and institution of the Fund.

The year 1887 was of historical importance as the fiftieth anniversary of the reign of the Sovereign of these realms, and a strong desire was manifested that gardeners and others engaged or interested in horticultural pursuits should identify themselves with some object commemorative of that auspicious event.

The columns of the horticultural press were crowded with suggestions as to the most appropriate form in which united expression could be given to this desire, and Mr. C. Penny, gardener to H.R.H. the Prince of Wales at Sandringham, issued a proposition, published on February 10th, that met with a prompt and warm reception; suggestions of a similar nature were made almost simultaneously by Mr. H. J. Clayton, of Grimston Park, Tadcaster, and Mr. J. Udale, of Elford Hall, Tamworth.

Sympathy with the object was spontaneous, and on the 24th of the same month Mr. Penny was able to announce publicly that the first promised annual subscription to a fund for the benefit of the orphan children of gardeners was made by Mr. E. J. Beale (of Messrs. James Carter & Co.), who was immediately followed by Mr. William Bull and Messrs. Sutton & Sons. Mr. H. J. Veitch also promised support, and subsequently gave a munificent donation.

On March 17th a list of ninety subscribers was published, and on the 22nd of the same month a provisional Committee was appointed in London to devise a plan of action that would best meet the end in view.

On April 14th an appeal was made to gardeners for their adherence to the project then formulated, and the returns justified the holding of a general meeting for receiving the report of the Provisional Committee, and considering the rules at the same time presented.

This meeting was held on July 12th, in the gardens of the Royal Horticultural Society at South Kensington, and the Gardeners' Orphan Fund was formally established. Officers were then appointed and Sir Julian Goldsmid, Bart., M.P., elected the first President, his sympathy with the object in view being expressed by a generous contribution to the charity.

Considering the short lapse of time since the movement was originated, the Committee point with gladness to the results achieved. The financial statement shows the amount received, invested, and disbursed. In the establishment of institutions initiatory expenses are necessarily incurred that are essentially of a special nature, and which are not called for in subsequent management. The fact that these expenses have been met, and provision made for electing six children the first year, is, if not unprecedented, certainly most gratifying, and sincere thanks are tendered to all who have contributed to this most satisfactory result.

The Executive Committee desire to recognise the valuable and effective co-operation of the several local secretaries, now numbering ninety, who bring the claims of the charity to the notice of gardeners and their friends in their several districts, and reliance is placed on their further aid and continued efforts. The incentive to this is an ever-increasing number of applicants for the benefit of the Fund, and this fact demonstrates the necessity for its existence.

The Committee also desire to acknowledge their indebtedness to the Council of the Royal Horticultural Society for permitting their gardeners

at Chiswick to be the head-quarters of the Fund; to the Duke of Bedford for the facilities afforded for the Covent Garden Fête, and for his handsome donation; to the proprietors and editors of the gardening journals for the great interest they have shown in the charity, which has been strengthened by the aid thus rendered; and to the auditors, Mr. W. Sharp and Mr. C. H. Sharman, the latter of whom kindly acted on this occasion for Mr. John Fraser.

The death is greatly lamented of Mr. John Woodbridge, who was a valued member of the Committee and a true friend of the charity.

Mr. William Poupert, of Twickenham, has been elected a member of the Committee in the place of the late Mr. Woodbridge, and Mr. A. Assbee of Covent Garden in the place of Mr. Wood Ingram, resigned. The members who retire, according to the rules, are Messrs. Barr, Douglas, Holmes, Sharman, Smith, Turner, and Williams, and the four last named are recommended for re-election. Mr. G. W. Cummins, The Grange Gardens, Hackbridge; Mr. C. Howe, Benham Park Gardens, Newbury; and Mr. J. Walker, Whitton, are recommended for election as new members. The retiring Auditor, Mr. John Fraser; the Treasurer, Mr. J. B. Haywood, and the Hon. Secretary, Mr. A. F. Barron, are also nominated for re-election.

To all organisations designed to meet the necessities of gardeners after their term of labour is over, or who are temporarily incapacitated, the Executive Committee of the Gardeners' Orphan Fund wish unbounded success, and for their own charity they bespeak practical sympathy—help for the helpless. Of these, unfortunately, there is no lack, for, to cite the words of our President in his address last year, "every one is liable to sickness, and now and then the head of the family is removed, and the children are left to battle with an eager and greedy world." Let us help them in the unequal contest.

CHAS. HENRY SHARMAN ..

Dated, 6th July, 1888.

Mr. Deal, in moving the adoption of the report, stated that when he was first called to take the chair at their meetings he little anticipated the success would be so great, but it showed what could be done when energetic men combined to attain a definite object. The report needed no special remark, but with regard to the balance-sheet he called attention to the substantial assistance the local secretaries had rendered, which was the more surprising considering their isolated positions. In considering the expenses he said that printing and stationery was a rather heavy item, but they had to establish a system of book-keeping and incur many expenses that would not be necessary for several years, as their books would carry them over a period of five years. The advertising item was an extremely small one owing to the generous assistance they received from the horticultural press, and the clerk's salary of £10 was also very small considering the great amount of work performed. He thought the result of the first year's work was highly gratifying, and the Gardeners' Orphan Fund might be regarded as a most successful institution. Mr. H. J. Veitch seconded the adoption of the report, and said the most satisfactory indication of their progress was the fact that at the end of their first year they were able to elect six children to the benefits of the Fund. The accounts were clear and favourable, and he wished it to be specially observed that one of the auditors was a chartered accountant quite independent of the Committee. The report was then adopted unanimously. The officers were then duly re-elected with the new members of the Committee, as suggested in the report, and after an alteration in Rule 2 by inserting the words "Orphans of gardeners or foremen in public, private, and market gardens" had been agreed to, the meeting was adjourned for the purpose of collecting and classifying the votes.

The following was the list of candidates, with the number of votes obtained, as subsequently announced, but, as was stated by the President during the evening, the Committee had the pleasure of electing the whole of the candidates.

1. ALBERT EDWARD BEST, seven years of age. Father a gardener for ten years; last employer, Cecil H. T. Price, Esq., Kenley, Surrey. Died 1887, leaving four children, aged respectively—three boys, 22, 17, 7; one girl, 13; without any means of support; the eldest son (22) at present in hospital; mother living, quite unable to work; in receipt of parish relief. 24, Hartley Cottages, Purley, Surrey.

2. RALPH JOSEPH GARDINER (131), nine years of age. Father head gardener to A. Akers-Douglas, Esq., M.P. Died, 1884, leaving six children, aged respectively—four boys, 14, 12, 11, 9; one girl, 7 (one since dead); entirely dependent on their grandparents; mother in delicate health. Gaunt's House, Wimborne.

3. EMILY MABEL HYDE (245), five years of age. Father sixteen years as head gardener; last employer, R. Christy, Esq., Watergate, Emsworth, Hants. Died 1888, leaving nine children, aged respectively—four boys, 15, 12, 6, 10 months; five girls, 14, 10, 7, 5, 2; entirely dependent on friends, no income whatever; mother living. Bush House, Watergate, Emsworth, Hants.

4. ALBERT LACEY (166), five years of age. Father employed ten years as second gardener to S. C. Gibbons, Esq., Walstead, Lindfield. Died 1887, leaving four children, aged respectively—one girl, 13; three boys, 9, 5, 2, totally unprovided for, mother living; supports herself and family by charring. Walstead, Lindfield, Sussex.

5. EMILY SMITH (153), three years of age. Father twenty-one years employed as a gardener in different situations; last employer, Mrs. Walker, Blythe Hall, Notts. Died 1885, leaving ten children, aged respectively—one boy, 17 years; nine girls, 19, 15, 14, 12, 10, 6 (twins), 5, 3, totally unprovided for; mother living, earns a little by needlework. Opposite Steam Saw Mills, Albert Road, Retford, Notts.

6. GEORGE SMITH, five years of age. Father head gardener for twelve years; last employer, J. F. Schwann, Esq., Oakfield, Somerset Road, Wimbledon. Died 1887, leaving three children, aged respectively—one girl, 14; two boys, 10, 5, without any means of support; mother living, supports herself and children by needlework, nursing, &c. 10, Belvedere Cottages, Church Road, Wimbledon.

7. VICTOR SPYERS (88), ten years of age. Father Orchid grower for eight years to Sir Trevor Lawrence, Bart., M.P. Died 1883, leaving four children, aged respectively—two boys, 10, 8; two girls, 11, 6, totally unprovided for; mother living, receives 5s. per week from husband's former employer, and about 6s. per week rent of cottage built from the "Spyers' Memorial Fund." Brickyard, Broad Mayne, Dorchester, Dorset.

8. WILLIAM SAMUEL STANNARD, four years of age. Father fifteen years employed as a gardener; last employer, Rear-Admiral R. R. Cator, Hazlehurst, King's Langley. Died 1888, after long illness, leaving three children, aged respectively—two boys, 4 years, 10 months; one girl, 2½ years; without any means of support; mother living. Adrian Road, Abbot's Langley, Herts.

9. ETHEL STAPLES, five years of age. Father a gardener for twenty-eight years; last employer, Henry Oppenheim, Esq., Chipstead Place, Sevenoaks. Died 1887, leaving eight children, aged respectively—five girls, 23, 22, 20, 7, 5; three boys, 17, 15, 12, unprovided for; mother living. Chipstead, Sevenoaks, Kent.

10. ALFRED SWANBOROUGH (171), seven years of age. Father Lead gardener for ten years; last employer, P. Ricardo, Esq., Bramley Park, Guildford. Died 1885, leaving four children, three boys, aged respectively—11, 8, 7 (one since dead); supported entirely by relatives; mother died 1881. Bridge Road, Godalming, Surrey.

THE DINNER.

THE first anniversary dinner and gathering of gardeners in connection with the Gardeners' Orphan Fund was held last Friday evening at "Cannon Street Hotel." There was a very large attendance, about 200 being present. Sir Julian Goldsmid, Bart., M.P., President of the Fund, occupied the chair, and among those present were Dr. Masters, Dr. Hogg, Messrs. G. Deal, Shirley Hibberd, H. J. Veitch, H. M. Pollett, J. R. Bourne, W. Bull, J. Willing, N. Sherwood, J. Laing, J. Hudson, R. Dean, H. Cannell, A. F. Barron, J. Wright, B. Wynne, W. Richards, H. J. Clayton, T. Garnett, A. Dickson, W. Paul, H. Williams, J. Weeks, T. W. Sanders, D. T. Fish, J. Cheal, J. Roberts, E. Molyneux, H. Turner, A. Assbee, H. J. Baker, S. Ollard, T. Manning, G. Nicholson, H. Herbst, H. Ross (Perth), C. Ross, D. Cuthbertson (Paisley), J. Hudson, J. Willard, W. Wildsmith, W. Holmes, J. Smith, &c.

The loyal toasts having been given from the chair,

The PRESIDENT proposed "The Gardeners' Orphan Fund." He said it was only twelve months ago the previous day that some of them had the pleasure of assembling in the Royal Horticultural Gardens in order to initiate the Gardeners' Orphan Fund. The idea originated with Mr. Penny, the much-respected gardener of the Prince of Wales at Sandringham, and received a ready support from a large number of friends of horticulture. The result of the action then taken was that at that meeting the Society was organised, and if he might venture to say so Mr. Deal took upon himself the lion's share of the work, and had done it well. (Cheers.) He had shown not only great energy and zeal in the cause, but great discretion in the management of the business, and although he had been well aided by the most energetic Committee and others who had given means and personal assistance, his example had been contagious, and had led to the wonderful success which had already

attended the Fund. (Cheers.) It was only twelve months since the Fund had been established, and already they had had an election of candidates who had had the benefits of the Fund conferred upon them. In order to show them in what a good cause they had enlisted, he desired to direct their attention to two of the families who had been relieved. He mentioned one case of a gardener who had died leaving a widow with nine children. They had no income whatever, and no man would imagine that one poor woman could earn by her labour sufficient to maintain a family of nine children. Consequently they saw what a good work they had done in establishing a fund that could afford the necessary relief. Another case which was equally interesting was that of a gardener who had left ten children, the eldest nineteen and the youngest three years of age. The mother did a little needlework, and the elder children did something, still there was room for the charitable work which had been done by a Society such as that. (Cheers.) He thought they could see by those two examples how much room there was for the aid of such a Society, and to what good results it was likely to lead. They had had that day an election, and six candidates were chosen; but fortunately the success of the Fund had been so great that the Committee had generously decided that they would elect all the candidates to the benefits of the Society. (Cheers.) Consequently instead of having only six, they had now altogether ten annuitants on the list. (Cheers.) There were others still waiting, and even since the election that afternoon one most deserving case had applied for the benefits of that charity. So that they would see that there was yet much for them to do. They would remember that many of their friends in Covent Garden assisted that Fund by a magnificent fête, the like of which he for one had never seen. (Cheers.) He trusted that something of the kind might become one of the established institutions of the Metropolis in aid of the Gardeners' Fund. (Cheers.) He would venture to suggest to the Committee that on a future occasion there should be a universal charge for admission, which should apply to the Committee and everybody else. (Cheers.) He believed that the result would be that a considerable sum would be added to the funds of that laudable institution. He would like to say a word in approbation of Mr. Laing and Messrs. Wills and Segar for the way in which they had decorated the tables and room with magnificent plants and flowers, and of friends who had sent splendid fruit. (Cheers.) Such a display was seldom seen.

Now as to the financial position of this yearling—the Gardeners' Orphan Fund. It was a yearling on the previous day, and he found that already the donations, including the Covent Garden fête, amounted to £1131, and the general subscriptions, including Covent Garden fête, amounted to £302. What was more important was that the local secretaries' donations and subscriptions amounted to £382. The life of an institution like that was in the local interest and local support, and consequently he was delighted to see that a large sum had been received from the different parts of the country. He trusted that that sum would go on increasing. In addition to that there was the modest sum of dividend upon £500 consols amounting to £4 17s. 10d., so that the total receipts were £1821 8s. 9d. (Cheers.) The expenditure had amounted to £1003. Two sums of £508 and £495 had been invested. The expenses of management had not amounted to a sum of £200, so that for that sum the Fund had been established and managed, and made known to all the horticulturists of England. (Cheers.) It was the most economical start he had ever heard of, and it promised well for the future. In addition to that Mr. Deal, like a wise man, liked to have at the first of their annual dinners a good balance at the bankers, and he found that he had the very handsome sum of £604 14s. 8d. there, in addition to the £1003 invested; so that the Society really started with money invested, or ready for investment amounting to £1600. He would like to know where there was another Society of such a kind as that which had had such a promising start. (Hear, hear.) The Fund had appealed to a large number of the public because they saw that the cause in which they were enlisted was a good cause, which commended itself to the heart of every man. It was the cause of the widow and the orphan. (Cheers.) The widow and the orphan were the source of deep interest to every man at that table. The appeal was an appeal to the best instincts of the human heart. He rejoiced that the effort which had been made had been so successful, and he ventured to prognosticate much greater success in the future, and that this would be one of the most popular institution of that excellent and highly intelligent class the gardeners. (Cheers.) He had been talking to some neighbours about the difference which existed between the English and the foreign workmen as to technical education. Fortunately for them and the general public the gardeners had never been deficient in that first element of education which was requisite for every trade and profession, because there was not one gardener who had not had to learn something scientific and something technical in order to obtain the position which he occupied. (Hear, hear.) He rejoiced to think that England was not behind other countries in the intelligence and interest which was devoted to horticultural pursuits. It was therefore with the greatest pleasure that he accepted last year the office of President, and it was with equal pleasure that he presided over that dinner. He rejoiced to see so many assembled to give an earnest and hearty support to the Gardeners' Orphan Fund. (Cheers.)

MR. G. DEAL responded. After returning thanks for the manner in which the toast had been proposed, he mentioned that Mr. Willing had kindly given him 10 guineas towards the Fund. (Cheers.) Ever since they put him into the position which he occupied he had received the most cordial support from the gentlemen who had assisted him at

the various meetings. When they looked at the splendid result of their efforts they might say that as they had sown so they had reaped. (Cheers.) He thought that they had laid the foundation upon which he trusted they would erect a fabric that should extend its shelter throughout the length and breadth of the land. (Cheers.) Nothing could be more gratifying than to find that they had touched the hearts of gardeners throughout the kingdom. That was shown by the manner in which they had responded to the appeal that had been made to them. Having once put their hands to the plough he hoped that they would never leave it. (Cheers.) Having thanked them for drinking the toast of the Gardeners' Orphan Fund he had now to propose another toast, namely—that of "Kindred Institutions." (Cheers.) It seemed to him that they had now a complete chain of institutions for the gardening fraternity. They had their Gardeners' Royal Benevolent Institution for decayed, their Benefit and Provident Society for sick, and now they had added just the last link—namely, the Gardeners' Orphan Fund. He was quite sure that he expressed the most hearty and cordial sentiment of all the gentlemen with whom he had the honour to work, when he said that while they gloried in and were proud of the success of their own institution, the Gardeners' Orphan Fund, they heartily wished equal success to kindred institutions. (Cheers.) Therefore he had much pleasure in proposing that toast. (Cheers.)

MR. SHERWOOD, in responding to the toast, said he could congratulate them most heartily on the success attending their first dinner. He had been told that it was some forty-eight years ago that the first dinner of the Gardeners' Royal Benevolent Institution took place, when only some thirteen or fourteen were present. He felt that the greatest thanks were due to Mr. Penny and Mr. Deal for having originated that Fund. He hoped that the institution would flourish as the Gardeners' Benevolent had done.

MR. HUDSON, on behalf of the Gardeners' Sick Fund, also replied. He said that he was happy to say that the fund which he represented was doing a considerable amount of good work. Like a good many other societies, however, they had had a struggle, but he was glad to say that this year they were increasing in numbers at the rate of about 33 per cent., and now had some 300 members.

DR. MASTERS, who next proposed "Success to Horticulture," said that everyone in the room he presumed lived by and for horticulture, and therefore when they drank success to horticulture they really in fact drank to their noble selves. (Laughter.) If he might be allowed to say so, his experience was that horticulturists as a body seemed rather deficient in co-operative power. They had allowed the public to look upon horticulture as something exceedingly pleasant and pretty, very nice for recreation; but they had not educated the public at present up to the view that horticulture was a national industry. (Cheers.) He should like to ask them what national industry they could mention which would surpass horticulture. All were absolutely dependent upon horticulture, and he did not know any single industry in this country of more importance. If he were at an assembly of farmers he should be told that agriculture was the most important. But let them read their Bible, and they would find that gardeners existed before the plough. (Laughter and cheers.) But coming to modern times, he asked them whether they could not get three and four times as much out of the land as the farmers did. (Hear, hear.) They might depend upon it that farmers must to a great extent be dependent upon the methods which the gardener followed with so much success. He was glad to see symptoms of their co-operation—one was the present gathering. Never in his own experience had he known gardeners jump at anything as they had at that institution. (Hear, hear.) They had now before them a splendid instance of co-operation. Gardeners had in this instance pulled together more constantly than ever they had done; but if they had always done it, horticulture would have taken the position which he claimed for it in the industries of the country. They now heard that it was proposed to appoint a Minister of Agriculture, Horticulture, and Forestry. Now, he was not one of those who thought that gardening wanted anything from the State. He did not believe, in this country at any rate, that State-aided institutions were any good, but he did believe that gardeners could aid the State, and therefore he rejoiced that there was some prospect of a Minister of Agriculture and Horticulture, because then the gardeners could exercise their influence upon the powers that be for the good of the State in general. (Cheers.)

MR. H. J. VEITCH proceeded to reply to the toast after it had been warmly honoured. He said he had been at some loss to understand why he had been selected to reply to that toast. Perhaps it was because he was a gardener, as a gardener should be—a married man without encumbrance. (Laughter.) There were, it seemed to him, three classes of the trade associated with the toast, the first being the nursery and seed trade, who in their corporate capacity employed a great number of persons, and with them he should not forget the horticultural building trade. The next class of persons who were concerned particularly were the gardeners, of whom he believed there were at least 20,000 names enumerated. Let them also remember the number of people employed in fruit gardening on land which had been converted from farming purposes. That brought in another class of people—those who were occupied in preserving the products of those gardens. Thus the number of people dependent upon horticulture in Great Britain was immense, and he felt proud to be called upon to speak for such a representative body. There were then numbers of employers who derived pleasure from their gardens in this country. If gardens were done away with his hearers could imagine the loss of pleasure tha

would ensue. They had only to look at the financial position of themselves in the country, and he thought then that in comparison with some other trades they would admit that they did what they could to help the unfortunate. (Cheers.)

MR. J. R. BOURNE concurred in the remarks of Mr. Veitch upon the importance of horticulture.

MR. WILDSMITH also briefly replied in a warm-hearted speech, with a genuine gardening ring prevailing that met with great acceptance.

The next toast was that of "The President, the Chairman," which DR. HOGG proposed. In so doing he said that at the formation of the Fund everything seemed prosperous, but they could not tell where to find a President. They knew the success of movements such as that depended very much upon the way in which they were floated. They wanted to have a man of position and good name, and the first thing they had to do was to look out for such a man. They were all very much troubled upon that point, but one day his good friend, Mr. Deal, came towards him, and his (Mr. Deal's) face was beaming more than it usually did. (Cheers and laughter.) He (the speaker) said to himself, "There's good news for us." So he asked Mr. Deal, "Well, how are things going?" Mr. Deal said, "I have, I think, got a President." "Indeed, who is he?" he asked. "Well, it's rather a secret," replied Mr. Deal, "but you need not say anything about it; it is Sir Julian Goldsmid." (Cheers.) "Well," replied he (the speaker), "if you have got Sir Julian Goldsmid success is assured." (Cheers.) Well, Sir Julian had become the President, and he did not think they could have done better, for he was known for his philanthropy and largeness of heart throughout the world. That was not his only claim to consideration from them, for he not only had a consideration for gardeners' orphans, but he also had a consideration for gardening and gardeners. To have had anyone presiding over that Society who was not a gardener and could not talk about gardening would be an anomaly. (Hear, hear). But Sir Julian was not such a man, and he trusted that they would see him spared for many years to preside over the institution. (Loud cheers.)

THE PRESIDENT, in responding, said he had always taken great interest to the beauties which gardeners cultivated. When visiting his friends, if asked whether he would like to go shooting or fishing he generally replied, "If you don't mind I should like to waste your gardener's time for the rest of the morning"—(laughter and cheers)—and he had never come away from wasting a gardener's time without having learned something of the greatest possible interest. The gardener's art was one of which they might well be proud. (Cheers.)

MR. R. DEAN then gave "The Vice-Presidents and Trustees," to which MR. BULL and MR. POLLETT briefly replied.

MR. SHIPLEY HIBBERD, in proposing "The Auditors, Officers, and Committee," said he was astonished at the example the gardeners had shown of unselfish enthusiasm in founding that institution, as by it they could not expect to benefit themselves personally. He did not know of any society which had made such progress in the course of twelve months, and when he heard the floating of it had cost £200, he said it was nothing, because they had accomplished the unity of gardeners. He had seen the officers of the Society grinding away at work on its behalf. The success of the Society was in the first place due to the fact that it had originated with the gardeners themselves, and in the next place they had had the good sense to accept the assistance of good business men who knew how to "turn the mangle." (Cheers.) Much yet remained to be done for the Fund, for they had that day incurred a great responsibility in placing ten applicants on its funds.

MR. H. HERBST and MR. A. F. BARRON briefly responded to the toast, after which

MR. G. DEAL proposed, "The Local Secretaries." He recognised with the utmost cordiality the great assistance that the Fund had received from the local secretaries. When the idea of appointing local secretaries throughout the land was proposed it was little contemplated that, situated as gardeners generally were, they would be able to take up the cause as they had done. But they had worked in the most zealous manner. (Cheers.) He must express the great astonishment and pleasure felt by the Committee when they found the returns from the local secretaries had amounted to the very handsome sum of £382. He could express the most profound gratitude on the part of the Committee for that. (Cheers.)

MR. D. T. FISH responded, addressing his auditors as "brothers of pen, spade, and knife," he said that someone had spoken of the enterprise and energy displayed by gardeners, but he thought that if there was anything they had cause to be proud of it was the starting and so far successful working of the Gardeners' Orphan Fund. If ever there was a practical sermon preached it was in their Council Room that morning, where they saw exemplified the scriptural phrase that "pure religion and undefiled is to visit the sick, the fatherless, and the widow." (Cheers.) He was proud of the gathering and the leader which they had that night, and he felt that this was only a beginning of the great work which was before them. (Hear, hear.) As one of the local secretaries he had felt ashamed at being only able to send a contribution of £12 10s., but he anticipated sending £50, and he would not rest satisfied until he could send £50 from Suffolk. (Cheers.) He hoped that they would work together as one man not only to make the Institution a brilliant success, but to make it so successful that none of their orphans might ever want aid. (Cheers.)

MR. CLAYTON also replied, expressing the pleasure he had in coming from Yorkshire to be present at such a splendid meeting on behalf of so good a cause.

The CHAIRMAN briefly proposed "The Visitors," remarking that they not only had English friends, but also foreign. (Cheers.) They had M. Margottin of Paris there, who, as they knew, was one of the most celebrated of the growers of Roses in France. He thought that that fact showed that the interests of that Society were not confined to this country. (Cheers.)

MONSIEUR JULES MARGOTTIN responded in French. He expressed the satisfaction which he felt at being present on that occasion, and his appreciation of the benefits which the Orphan Fund would bring about. He hoped that next year they would double the number of their candidates, and he concluded by drinking success to the Fund. (Cheers.)

MR. GARNETT also replied, saying, that in Yorkshire there had been a very warm feeling in favour of the Fund, which he trusted would have a prosperous career.

MR. G. DEAL, who next proposed the toast of "The Press," attributed a great deal of the success the institution had met with since its formation to the assistance it had received from the Press, which had communicated every month to the public the progress of the Fund.

MR. WRIGHT in responding said that the foundation had done something more than bring about the unity of gardeners, as it had united the Press. Although divided in opinion sometimes upon the various matters brought before the public, the Press was yet happily united in furthering the interests of such societies as that. (Cheers.)

MR. WYNNE also briefly replied to the toast, confirming the previous remarks, and hoping the Press would always have a good account to give of the progress of the Fund.

This concluded the list of toasts, and on the motion of DR. HOGG a cordial vote of thanks was passed to Messrs. Low & Co., Messrs. Laing and Co., Messrs. Wills & Segar, Messrs. Webber, Messrs. Lane & Son, Messrs. Paul & Son, Messrs. Cannell & Sons, Messrs. Cheal & Co., Mr. T. Francis Rivers, Mr. C. Turner, Mr. J. Walker, Mr. G. Munro, and Mr. Webber, who had supplied plants, flowers, and fruit with which the tables and the room had been plentifully supplied and tastefully decorated.

During the evening selections of vocal music were given under the direction of Miss Mary Belval, Miss E. Champion presiding at the pianoforte.

CAMELLIAS.

IN an old span-roofed house having high front sashes in an Exeter garden is a fine example of Camellia culture. The house runs north and south, and is 32 feet long. The Camellias are planted in a bed in the centre of the house, and which, with the exception of the flag passage at the sides and ends, they completely fill to the height of 14 feet with healthy wood and large dark green leaves as close together as a well kept healthy Yew hedge. The branches having in the course of the last few years reached the glass, Mr. Sellick very properly headed them down to the level of the sides and ends last spring with the best possible results. The border at the same time had a few inches of the surface soil removed, and good turfy loam supplied as a top-dressing, giving the whole a good soaking of tepid water, with subsequent waterings of liquid manure at the roots. Copious syringings with clear water were given morning and afternoon at closing time after the plants had flowered to insure healthy growth being made, preparatory to yielding a rich harvest of flowers next winter and spring. When the plants have completed their growth abundance of fresh air is admitted to ripen the wood properly. — H. W. W.

STRAY NOTES.

A LOVELY white Cattleya was in bloom at Messrs. J. Veitch and Sons' Nursery, Chelsea, the other day. It was a strong plant, with four leading growths, and bore nine flowers. It differed only from C. Wagneri in having a single narrow purple line down the centre of the lip. The houses in this establishment were very gay, the Odontoglossums and Dendrobiums alone repaying for a visit; but the Lælia purpurata, with hundreds of blooms in various shades of colour in the large Cattleya house, was to my mind one of the finest sights imaginable. Odontoglossum madrense is very distinct, and I have seen it well grown by Dr. Duke at Lewisham. The plants were in pots suspended near to the glass in the cool house, where the pseudo-bulbs increased in size each year. The blooms of this useful species remain in perfection for a long time.

Barkerias were also remarkably well grown in the same garden. They occupied the roof of a small lean-to house. Some were in baskets, others on blocks of wood, either of which seemed to suit them. Very little material of any kind was used about the roots, but they were exposed to plenty of air and light, and during the season of growth received abundance of water, but when at rest water was almost entirely withheld. Since my visit Dr. Duke's

interesting collection of Orchids has been sold, and many valuable varieties have passed into other hands.—G. W.

CYPRIPEDIUM MEASURESIANUM.

HYBRID *Cypripediums* are now becoming very numerous, but there seems to be no limit to their variability, and new forms are constantly being raised and sent out, all with some claims upon the consideration of Orchid growers. Mr. R. H. Measures of Streatham has given special attention to the *Cypripediums*, with the result that his collection is now a remarkably rich one, including most of the named species, hybrids or varieties, together with several seedlings that have not yet flowered. One of the recent hybrids as yet but little known is represented in the woodcut (fig. 5), kindly lent by Mr. B. S. Williams, who is now distributing the plant. This authority thus speaks of *C. Measuresianum*:—"It is the result of a cross between *C. villosum* and *C. venustum*, and has leaves 5 to 8 inches long by 1 to 1½ broad, dark green on the upper surface, and marked with purple on the under side; flower scapes purple, hairy as in *C. venustum*; dorsal sepal ovate-lanceolate, yellow, margined with white, and veined with yellowish green; petals similar in shape to *C. villosum*, and having the same varnished appearance, light brown purple changing to bright orange, suffused on the upper half with purple; lip large, orange tinted, and veined with purple brown."

CARNATION NOTES.

I IMAGINE one of the least studied points in the cultivation of Carnations grown out of doors is that of propagation. As a rule the young shoots are layered when a spare space of time can conveniently be had in which to overtake this work, and the result very often is small not very well-rooted plants, either to stand the winter when layered or planted out too late to be established before winter. The proper time to layer is, directly the shoots can be had strong enough, when they root very rapidly, and are ready for planting into beds or nursery lines in early autumn, with good roots and strong healthy shoots. The result in the ensuing summer is beds of plants each with many flowering stems, instead of the puny plants incapable of throwing more than one weakly flower stem, and which is more often to be met with in gardens than the kind I am recommending. Early propagation is therefore the point of all others which has the strongest bearing for good in Carnation culture.

Where there are plenty of plants and fine flowers are desired it is a good plan to freely thin the buds, so those left become large. The difference in size is at least one-third, and the petals of the thinned flowers are much broader, giving the flowers a fuller appearance, and adding greatly to their attractiveness. Just now we have Mrs. Sinkins Pink in quantity, some with unthinned flower stems, and others with only one bloom left to a stem, and the result is that no one would think of taking the former, so much finer are the latter. *Souvenir de la Malmaison* is another case in point. There is no difficulty in obtaining flowers throughout the summer months fully 6 inches across if the stems are freely thinned of buds. Last winter we cut many 4 and 5 inches across; indeed, the way to have this lovely flower fine is to layer a strong shoot in autumn—up to October will do; keep it growing, shifting into a 5 or 6-inch pot when needed, and keep the flower stem thinned to one bud, and that bud will unfold a beautiful full bloom of the size noted. Those who have been contented with ordinary-sized flowers of this queenly variety would be surprised to find how much finer it is grown as just recommended.

As has been often pointed out, the easiest method of raising a stock of healthy free-flowering Carnations is by raising seedlings. There can be no doubt that for ordinary garden decoration purposes this is the easiest method, and the plants are very pleasing. But these are not so good for cut flower purposes as are those from well-grown plants of good sorts. Last season Carnations, Pinks, &c., seeded freely, and there was no difficulty in anyone raising a large stock of plants cheaply. If the seeds are sown in January and kept growing many flower the first season, and the next they are good bushes, with many flower stems. One is sure

FIG. 5.—CYPRIPEDIUM MEASURESIANUM.

to procure some pretty single sorts from seeds, which though not worth propagating further are useful for furnishing vases.—B.

TOM THUMB SAVOY.—There are many varieties of little Savoy offered for sale, but we fear they are all closely related to the old Tom, and it is a good one. Where size is wanted it need not be grown, but where fine little heads of excellent quality are required it will always find favour. It gains maturity in three months, and need not be planted until well into July. The plants are so dwarf and compact that they may be planted 15 inches each way, and it will be found that the whole space will ultimately be covered with choice compact heads.—M.

EVENTS OF THE WEEK.—The principal Shows of the present week will be the following:—Helensburgh (Roses) and Highgate on the 19th, the National Rose Society's Provincial Show at Darlington on Friday, the 20th inst., with Tibshelf on the 24th and Louth on the 25th inst., both Rose shows. The next meeting of the Royal Horticultural Society, in the Drill Hall, Westminster, will be held in conjunction with the show of the National Carnation and Picotee Society on Tuesday, the 24th inst. The exhibits will also comprize Ferns, Selaginellas, Ivy and Zonal Pelargoniums, &c. Messrs. W. & J. Birkenhead, Sale, Manchester, have promised an extensive collection of Ferns for this meeting.

— **THE Exhibition of the NATIONAL CARNATION AND PICOTEE SOCIETY** will be held in the Drill Hall of the London Scottish Volunteers, James's Street, Westminster (adjoining St. James's Park Station, District Railway), on July 24th. A luncheon will be provided at the "Hotel Windsor," Victoria Street, at 1.30 P.M., for members and their friends. Tickets 2s. 6d. each (exclusive of wine), to be obtained from the Secretary, or any member of the Committee. W. T. Thiselton Dyer, Esq., F.R.S., Director of the Royal Gardens, Kew, and Vice-President of the Royal Horticultural Society, has kindly consented to preside. Shirley Hibberd, Esq., will occupy the vice-chair. Subscriptions to the Society were due in January, and the Hon. Treasurer is S. Hibberd, Esq., 1, Priory Road, Kew, near London. Prizes will be paid as usual at 5 P.M. on the day of Exhibition.

— **THE WEATHER.**—Mr. C. Orchard writes from the Isle of Wight:—"Roses on the houses and dwarfs are flowering most profusely, the dark varieties keeping their colours well in this dull weather. The vegetables in the kitchen garden have made wonderful growth, the haulm of the Potatoes being of tree-like proportions. The hay crop is very heavy, and would compensate for the very light crop of last season if we were to have what is very much required, a period of bright sunshine, that would perfect the whole, and make a fruitful season. I have been very fortunate so far with my hay crop. I have made hay while the sun shone, and preserved it when it rained, but there is much about here spoiled. It is many years since I saw everything looking so green and luxuriant as now. The chalky hills, or downs as they are here called, which at this season of the year are generally of a rusty brown, are now a verdant green to the very tops. The Bee Orchis that are usually only a few inches high on these exposed places, are now to be found with flower spikes a foot long. Wild flowers on banks and hedgerows have attained unusual proportions."

— **"THE weather,"** writes a Sheffield correspondent, "still continues most unseasonable, a cold wind blowing from the north-east, with scarcely any sunshine, and cold rains almost daily. On Monday rain was falling fast, and had continued so to do with only two hours intermission since eleven P.M. on Saturday, or nearly forty-eight hours. The ground is saturated and very cold. Roses and Carnations will not be in flower with us before August, nor will Strawberries and Raspberries ripen before that time. Peas are making plenty of haulm, but are podding very slowly indeed. Potatoes also are making abundant top growth but scarcely any tubers. Although Sheffield is notably a very late district as regards vegetation, I have never previously known it so late as this season."

— **THE PORTSMOUTH SHOW.**—The Hon. Secretary, Mr. F. Power, writes:—"As it may interest your readers to know the result of popular prices of admission, I give you the exact number of visitors on each day at our Show last week. First day, 661 at 1s.; 1571 at 6d.; second day, 6086 at 3d.; third day, 14,826 at 1d.—total, 23,144. Had the weather been fine no doubt the numbers would have been greater, but a gale of wind and snow falling on the second day was anything but favourable for flower shows."

— **A CORRESPONDENT** states that "At the recent Rose Show at Ryde, I.W., a BEAUTIFUL BANK OF ORCHIDS AND FERNS were

arranged in the Concert Hall and exhibited, not for competition, by Mr. J. Earle, gardener to Henry Grosse Smith, Esq., The Priory, St. Helens, I.W. The *Laelias*, *Dendrobiums*, *Cypripediums*, *Odontoglossums*, *Oncidium*s, *Thunias*, *Masdevallias*, *Epidendrums*, &c., in their several varieties formed an attractive feature in the Exhibition."

— **THE GUERANDE CARROT.**—"B." sends this and the following note—"I have been highly pleased with this intermediate sort, which comes into use as quickly as the Early Horn, and very soon outgrows that sort. It entirely supersedes the Early Nantes, and grown alongside Sutton's Early Gem it is slightly ahead of that fine variety. Grown in the open garden and on a south border the results have been alike in these respects."

— **"ANOTHER vegetable worth noting is EARLY PURITAN POTATO,** which comes nearer to the standard of good quality than most sorts. We tried it lately with some other new varieties, and it gave much satisfaction, and is marked as a main cropper for another season. Veitch's new early Pea is also a decided step forward as regards earliness, and from Webb's Early Gem Tomato we gathered a large crop of good fruits in May and June. This is an extremely free variety, and new to me."

— **TOMATOES AT CHISWICK.**—The old Rose house in the Royal Horticultural Society's Garden is this season given up to the cultivation of Tomatoes. The house is a light airy structure, about 100 feet in length by 30 feet in width, and contains some 450 plants, planted out in four borders, two on each side of the central walk. The plants are grown with single stems, and trained to stakes about 6 feet in height. The seed was sown early in March, the planting out taking place about the middle of April. Ordinary garden soil is that used. A capital set of fruit has been obtained, and the plants are in vigorous health. Amongst all the sorts bearing the name of Perfection there is a great family resemblance, and of this most useful type producing smooth, solid, scarlet-coloured fruits, there are some 250 plants in the collection. Ham Green Favourite, certificated last year, is a variety worthy of note, being much esteemed at Chiswick. Horsford's Prelude is an American introduction, and will be appreciated by those who like a somewhat small Tomato. It produces its beautiful deep scarlet fruits in clusters, sometimes numbering as many as eighteen fruits, and bearing to within 6 inches of the ground. The plants are characterised by a stocky and compact habit of growth. Early Scarlet Tennis Ball is a round Plum-shaped fruit which is produced in clusters—a very free setter; a good sort to cultivate where quantity is a desideratum. Laxton's Open Air, a good early variety and a free setter, and that good all-round variety, Hathaway's Excelsior, find a place in the collection. Golden Queen is a very fine yellow-skinned variety, certificated by the Royal Horticultural Society's Fruit Committee two years ago. In a lean-to house adjoining is a collection of about fifty varieties, grown in 12-inch and 16-inch pots, and containing some of the newer sorts, which promise well.

— **A MEETING of the Executive Committee of the YORKSHIRE ASSOCIATION OF HORTICULTURAL SOCIETIES** was held on Monday evening last at the Grand Restaurant, Boar Lane, Leeds, Mr. Jos. Smith, President, in the chair, and at which delegates were present from the various societies held at Leeds, Sheffield, Barnsley, and Rotherham. After disposing of a very enjoyable tea, hospitably provided for the delegates by the Leeds Paxton Society, business was proceeded with, and the following resolutions adopted:—First, That the minutes of last meeting be confirmed. Second, That the annual meeting of the Association be held at the Grand Restaurant, Boar Lane, Leeds, on Wednesday, August 1st. Programme for the day's business to be as follows:—10.30 A.M., Meeting of delegates for the transaction of business; 11.45 A.M., Luncheon for delegates and visitors; 1.10 P.M., Excursion to Oakworth House Gardens, the residence of Isaac Holden, Esq., M.P.; 6.10 P.M., Return from ditto; 6.15 P.M., Tea at Grand Restaurant; 7 P.M., Lecture by Professor Jefferson "On the Chemical Action of Plants, with Microscopic Illustrations and Experiments." The question arising as to where the business of the Association be conducted and the annual meeting be held in 1889, the delegates from the Sheffield Floral and Horticultural Society signified that they were empowered to invite the same to Sheffield on behalf of their Society. This invitation was received with satisfaction by the Committee, and referred for final decision to the annual meeting. A resolution was also unanimously adopted that before the annual meeting takes place each Society in the Association be requested to hold a special general meeting:

of its members for the purpose of full discussion of the work done by the Association, with its present condition and future prospects. Some minor business, with a vote of thanks to the Leeds Paxton Society and to Mr. Smith as President, concluded the meeting.

— **CABBAGE COMPETITION.**—Encouraged by the great success attending the Cabbage competition which they inaugurated last year, Messrs. Stuart & Mein, seedsmen, Kelso, determined to hold a similar competition this season, and accordingly Friday last was the date fixed for the Exhibition. Last year, with a view to demonstrating the superiority of Mein's No. 1 Cabbage as an early variety, the firm offered a premium of £5 for the best pair of hearts grown from seed directly supplied by them, the date of Exhibition being in May. On that occasion the prize was won by Mr. D. Inglis, Howick Hall, Northumberland, with two fine Cabbages weighing 8½ lbs. This year a premium of £5 was again held out, to show that the Cabbage is also the best late variety, standing longest without bursting; and hence the reason for the Show being held much later than last year. No fewer than ninety-one pairs of hearts were sent in from all parts of Great Britain and Ireland. There was a large consignment from Cornwall, the counties of Kent and Devon being also represented, while specimens were sent from as far south as the Isle of Wight. Lincolnshire and Nottinghamshire in the Midlands also made a good appearance, while Scotch exhibits were received from as far north as Forres. Three lots were also forwarded from Parson's Town, Longford, and Ballymena in the north of Ireland. As on the former occasion, the Show took place in Kelso, and the large collection of Cabbages formed a very imposing display, the bulk well matured and generally in good condition. The Judges were Mr. Waite, nurseryman, Berwick-on-Tweed, and Mr. Elphick, of Messrs. Hurst and Son, seed merchants, London, who discharged their duties in a very satisfactory manner. Eventually three pairs were set apart, consigned by Mr. W. H. Divers, Ketton Hall, Stamford, Lincolnshire; Mr. James Lockie, Heatherslaw, Cornhill-on-Tweed; and Mr. Feddon, gardener, Scotby, Carlisle. After considering their respective merits the Judges awarded the premium to Mr. Divers for a pair of hearts of grand form and quality. Originally they weighed 8½ lbs. and 6½ lbs. each, but when divested of their outer leaves, in which manner they were judged, they together scaled 9 lbs. The hearts shown by Mr. Lockie and Mr. Feddon were also of a very meritorious description, but neither in form, compactness, nor quality were they equal to the first pair. Mr. James Hall, Kelso, exhibited a very good pair, and had they been more equally matched they would have had a fair chance of gaining the premium. Among the heavier of the Cabbages shown were two sent by Mr. E. Rilestone, Truro, Cornwall, which weighed 28 lbs., and other two pairs scaled 22 lbs. and 20 lbs. respectively.

PORTSMOUTH SHOW.

THE annual flower Show in aid of local charities was opened on the 10th inst. in the Victoria Park. The exhibits were more numerous than last year, and in order to provide the necessary accommodation the Committee have been compelled to make additional space. At two o'clock the Mayor, A. Addison, Esq., who was accompanied by his daughter, arrived, and the Show was at once opened. The Mayor trusted that the Show would be even more successful than those of previous years, and he regretted that every man had not the means to cultivate flowers and plants. Such exhibitions created emulation among gardeners, and in other ways, and did an immense amount of good, and he attributed the increase in the growth of flowers in Portsmouth of late years to the shows which had been held from time to time. The Judges had no easy task in awarding the prizes, the competition being very keen, especially with the cut blooms of Roses from Mr. W. Rumsey, Waltham Cross; Mr. Flight, Twyford, Winchester; Messrs. W. and G. Drover, Fareham. The latter also showed a collection of herbaceous flowers, which was highly commended, and a similar compliment was paid to Messrs. Cutbush & Son, Highgate, who exhibited a fine collection of foliage plants, and Mr. King of Lymington for double Begonias. Mr. F. Power, the popular Hon. Secretary, must be congratulated on the success of the Show, ably assisted by Mr. Hatch, the head gardener of the Park, and Committee. The total receipts for the three days amount to £275 4s. 5d. On Thursday, the charge for admission being 1d., no fewer than 14,706 visitors passed the turnstiles. The number of visitors exceeded that of last year.

The following is the prize list:—Eight stove and greenhouse plants.—First, Mr. J. Cypher, Cheltenham; second, Sir F. Fitzwigram, M.P. (gardener, Mr. J. Penford). Four stove or greenhouse plants.—First, Col. Pepper, Millford Hall, Salisbury; second, E. Bishop, Esq., Southampton (gardener, Mr. E. Hawkins). Three specimen Palms.—First, Mr. J. Cypher; second, Sir F. Fitzwigram, M.P. Miscellaneous collections of plants.—First, Sir F. Fitzwigram; second, E. K. Parsons, Esq. The amateurs of Portsmouth, dockyardmen, exhibited good collections

of plants. Ball bouquets and bridal bouquets, Mr. J. Cypher was well to the front.

Roses.—Forty-eight cut blooms, single trusses.—First, Mr. W. Rumsey; second, Mr. Flight; third, Messrs. W. & G. Drover. Twenty-four, three trusses to a bunch.—First, Mr. Rumsey; second, Mr. Flight; third, Messrs. W. & G. Drover. Twelve Teas, distinct.—First, Mr. Flight; second, Messrs. W. & G. Drover; third, Mr. Rumsey. Twelve Hybrid Perpetuals, dark, four distinct varieties.—First, Mr. Rumsey; second, Messrs. W. & G. Drover; third, Messrs. Ewing & Co., Havant. Twelve Hybrid Perpetuals, light, distinct.—First, Mr. Flight; second, Messrs. W. & G. Drover; third, Messrs. Ewing & Co. Twelve Teas or Noisettes, distinct.—First, Mr. Flight; second, Mr. Rumsey; third, Messrs. Ewing and Co.

Fruit and vegetables were well shown by Mr. Penford, and some very fine Tomatoes by Mr. Kimber, gardener, Borough Lunatic Asylum.

NIPHETOS.

A SHORT time since at Gomfield House, Exeter, we noticed a healthy plant of this beautiful Rose trained to a wire trellis fixed beneath the roof of a lean-to house having a south aspect. This vigorously growing tree Mr. Sellick, the gardener, informed us had yielded substantial blooms of pearly whiteness during the spring months, and it had every appearance of producing a good supply of such blooms during the summer and autumn months, as there is a good supply of hot-water pipes in the house with which to produce the necessary temperature during inclement weather. When the plant has ceased flowering and shed its leaves all weakly growths are cut back to one joint from their bases, and any unduly long and strong shoots are shortened back a little to promote a balance of growth.—H. W. W.

A PLAGUE OF EARWIGS.

EARWIGS were bad enough last year, but this season we have them already in as large numbers as in last September. Each of my Chrysanthemum pots has a hollow Teazle stalk laid on it, and when these are blown out every morning it is not uncommon to find as many as twenty earwigs in one stalk. I have found five or six in one *Maréchal Niel* Rose—not an old decayed one, which would be more likely to yield thirty, but in my best young bud in the show tent. They are in our house, in our clothes, in our boots, in our beds. In spite of the cold weather and of the slaughter from the Teazle stalks every morning the numbers are decidedly increasing. It is quite a business to collect and relay all the stalks in the Rose beds and round the Chrysanthemums, but we must increase them; and, with all our pains, I fear the greater part of our flowers and fruit will be spoiled.

However, "it is an ill wind that blows nobody any good;" the trout in the pool in my garden have a real good time when the earwigs are blown to them, and I find a large proportion of the visitors to my rosery are more interested in seeing the rise of the golden two-pounders than in looking at the Roses. I suppose there is nothing more to be done. I find the earwigs are much more quickly collected in the hollow stalks than in moss or flower pots, or anything else.—W. R. RAILLEM.

PROPAGATING ROSES.

CUTTINGS of ripened wood inserted in the open ground last autumn did not strike root nearly so well as usual, this being principally due to the action of the frost on the ground. The cuttings were repeatedly loosened, and although refixed several times this did not save more than one-third of those inserted. As a consequence more attention will be paid to the summer propagating, and others will do well to follow the example set, the aim being to secure as many dwarf Roses as possible, so as to be quite independent of the uncertain Briar and Manetti stocks. Plenty of cuttings are generally available for the method shortly to be described—many more, in fact, than can be found suitable in the autumn. Every shoot that has perfected a bloom is in the best possible condition for making into a cutting, and these should be taken with a heel or small piece of old wood attached, preserving the leaves and shortening to about three joints. Short firm lengths without a heel will also strike freely, these being cut cleanly across below a joint, and two or three sound leaves preserved.

It is of the greatest importance that the cuttings be inserted directly they are made, as should they flay badly, or be allowed to shrivel, however slightly, failure is certain. The first proceeding, therefore, should be to prepare deep boxes or handlights for their reception. Set these close to the foot of a north wall, or where little or no sunshine will reach them, not less than 3 inches of fine fresh loam with plenty of road grit or sharp sand being placed in, this being faced with more of the grit or sand. Then collect, prepare, and at once insert the cuttings with the aid of a blunt-pointed dibber. They may just touch each other all round, should press against the bottom of the holes, and have the soil firmly fixed about them. After being watered the boxes ought to be closely covered with squares of glass, or the handlights closed, neither being opened until the cuttings either need water or are rooted.

In this manner a number of serviceable little plants will be obtained suitable alike for planting out or pot culture. Very few varieties fail to strike when treated in this way, but those which never fail are Comtesse d'Oxford, John Hopper, Souvenir de la Malmaison, Etienne Levet, Charles Lefebvre, Capitaine Christy, La France, Madame Eugène Verdier, Gloire de Dijon, Maréchal Niel, Général Jacqueminot, Beauty of Waltham, Marie Baumann, Alfred Colomb, François Michelin, and Duke of Edinburgh.—W. I.

ROSES IN WINTER.

FROM June when Tea varieties are given abundance of air by day the advantages of moisture-holding floors over those that are flagged with stone, tiled, or cemented will be apparent to growers. When the doors and ventilators are open the moisture of the house is rapidly evaporated by the external atmosphere—that is, during bright dry weather. Fancy floors are dried almost as quickly as water can be poured upon them. If a certain amount of moisture is not maintained by frequently damping the available space there is quickly a very suitable atmosphere for the development and progress of red spider. Floors formed of ashes or gravel will hold ample moisture for the day at least, damping and syringing morning and afternoon being sufficient, but it is important that the syringe be used liberally once daily in order to keep the foliage free from red spider.

Red spider is much more likely to be a source of annoyance from the time liberal ventilation is given than earlier in the season. This being one of the worst enemies of the Rose under glass it must be watched for and exterminated directly it appears. There are many insecticides recommended for this purpose, and I have no word to say against any of them, but nothing surpasses a solution of powdered sulphur and water either for cheapness or effectiveness. A 2½-inch flowerpotful in each gallon of water, kept well stirred, and the plants thoroughly syringed, is enough to destroy red spider. The sulphur should be mixed like paste with a little water, and then the remainder added. The under side of the leaves must be well syringed with the solution, which must be allowed to remain on one, two, three days, or longer according to the weather. A bright sun is necessary to bring into full force the insect-destroying qualities of sulphur applied on this principle. No harm will be done by leaving it on, and therefore when once applied it can remain for three days if bright, and then thoroughly wash the plants with the hose or syringe. This is the only solution I have used for years whether spider makes its appearance on Roses, Vines, Peaches, Cucumbers, or any other plants, and have never known it fail. It is practically useless if the plants to which it is applied are shaded.

The borders in June may be mulched as a preventive of red spider. This will also prove beneficial to the plants by the retention of moisture about their roots without having constantly to water them or damping the surface, beyond the ordinary syringing. To apply rich manure as a surfacing in the plant's present condition would be injurious rather than beneficial. The border should be sufficiently fertile for at least the first two seasons; at the same time I am no advocate for borders being made too rich, which will encourage strong but soft growth that cannot be matured properly. All that is needed is to check rapid evaporation from the border. Manure that has been used for hotbeds, the refuse of Mushroom beds, anything of this nature, will accomplish the object in view.

While considering the summer treatment of the plants the question of shading them from the burning rays of the sun may be briefly considered. In houses that can be liberally ventilated no shade is needed. Full light and sunshine are essential to solidify and mature the growth as it is made. Tea Roses under glass in good health and condition will persist in growing later in the season than is desirable when the plants are subjected to early forcing, and shading, even if only slight, would encourage this tendency. It would delay the maturation of the wood until later in the season, and thus rob the plants of a portion of their rest that is so necessary to health, vigour, and good blooms the following season. Whether shade would be advantageous or the reverse when Roses are grown in houses provided with little or no ventilation is a matter that at present I cannot well answer; but it is certain that while such structures are admirably suited for forcing the Rose during the early part of the season they are not suitable during summer. I would not advise their construction, as although Roses may do well in them for a few years they are too confined for a hardy plant, and this means weakening their constitution and finally early death.—WM. BARDNEY.

[Our correspondent's reply to "S. S." (page 30), is received, but cannot be inserted this week.]

(To be continued.)

WINCHESTER.—JULY 12TH.

LIKE many other shows this year, this suffered materially through the extraordinary inclemency of the weather, and the majority of exhibitors who had entered were unable to compete in several of the classes; yet those who did stage blooms acquitted themselves well, and the Show on the whole was quite equal to this year's average of "provincials," if not above it. The collections were staged in the Guildhall, a fine building; but the arched roof being opaque, and one side nearly destitute of windows, the light streaming in from the other rendered the work of judging easy of those classes that faced it; but in the case of those facing the opposite direction the work was unusually difficult, and even the experienced Mr. D'Ombraïn has perhaps not often had his faculties more greatly taxed in adjudicating. He, however, made no

mistake, but the officials did in one instance in placing the second-prize card on a box to which no prize was given, though it was awarded to another stand of the same exhibitor, so no harm was done to him, though some of the on-lookers must have wondered "what the Judges could have been about" in that particular class. As an instance of the falling-off in exhibits only two lots of seventy-two blooms were staged out of seven entries, and more than half of the entries were withdrawn at the last moment from several other classes owing to the wet and extremely cold weather of the few preceding days.

In the great class in which prizes of £6, £5, and £3 were generously offered by R. Moss, Esq., M.P., Mr. Frank Cant, who appears to be in the ascendant this year, scored another triumph. The blooms were not "heavy" but remarkably fresh, and the darks very rich in colour. Mr. B. R. Cant secured the second prize, his stands containing several very fine blooms, though the weather had been cruel to many. In the class for thirty-six Roses, distinct, the last-named exhibitor won the first position with very fine blooms, Messrs. Keynes, Williams & Co. following with fresh but smaller examples; but in the next class of twenty-four blooms they took the lead with extremely neat, fresh, clean, and rich blooms, Mr. G. Prince being a dangerously close second with a somewhat heavier stand. For twelve H.P.'s of one variety the first and second prizes fell to Messrs. B. R. Cant and G. Prince respectively, both for Merveille de Lyon. We failed to obtain the name of the third prize-winner in this class. The corresponding prizes for twelve dark Roses were won by Mr. F. Cant, Mr. B. R. Cant, and Mr. E. Hillier, in the order named, the two former staging Ulrich Brunner, the latter A. K. Williams, all good.

In the next class, and a wonderfully good one it was, of twelve Teas or Noisettes (triplets), Mr. Prince was first with blooms of commanding excellence. Comtesse de Nadaillae, Catherine Mermet (fine), Princess of Wales, Souvenir Thérèse Levet (glowing crimson), Innocente Pirola, François Kruger, Madame de Watteville (extra fine), and Madame C. Kuster were particularly noticeable in the collection. Mr. F. Cant was second with fine blooms, especially of Madame de Watteville, Madame Bravy, Catherine Mermet, and Rubens; Rev. F. R. Burnside following with very neat, clean, even, but rather small blooms, good enough, however, to have won a higher position at many shows. In the class of twelve of any variety, Mr. F. Cant was first with Madame de Watteville, the petals twisted and spread out like wings, a charming stand. Mr. Prince was second with Souvenir d'un Ami, and Mr. B. R. Cant a very close third with Nipbetos. Still referring to the Teas and Noisettes, in the class not open to nurserymen, Mr. Burnside well won the chief position with twelve blooms, staging admirably Catherine Mermet (not a very large, but finely built bloom, to which the N.R.S. silver medal was awarded), Edith Gifford, Madame Cusin, Maréchal Niel, Madame Bravy, Souvenir de Paul Neyron, Souvenir d'Elise, Innocente Pirola, Madame Furtado, Souvenir de Thérèse Levet, Princess of Wales, and Madame de Watteville. Mr. F. W. Flight, Twyford, a most successful local grower, was second in this class, but first in the classes for twelve blooms in six, and for six blooms in three varieties, staging Madame Lambard, Catherine Mermet, Jules Finger, Edith Gifford, Madame de Watteville, and The Bride in excellent form.

In the amateurs' classes for thirty-six blooms Capt. Ramsey, Fareham, was first with very fine examples, notably of Baronne de Rothschild, Devienne Lamy, A. K. Williams, Merveille de Lyon, Adam, and Grace Darling; Mr. Flight following, his stand containing one of the finest blooms of the year of Merveille de Lyon, well winning the N.R.S. silver medal for the best H.P. in the Show. Mr. R. E. West was the remaining prizewinner with small fresh blooms. Mr. Flight was first with twelve triplets, a very good stand; and for twelve blooms the prizes went to D. Seaton, Esq., Bitterne; Rev. C. Eddy, Bramley, Basingstoke; and Mr. F. C. Birch, respectively, all staging neat fresh examples. An extra prize was granted in this class to Mr. Chaloner Shenton, his first exhibit, and as such most creditable, as the blooms, which were very fresh, were admirably arranged.

There was great competition in the class for twelve bunches of cut flowers, hardy or tender, Mr. Flight being placed first, and Mr. G. A. Inglefield, Tedworth Gardens, second. The Misses A. and B. Flight had the best stands of flowers for the table, and it is not often that greater taste in arranging flowers with Grasses and Ferns is exemplified than by the deft fingers of these ladies. Mr. C. Neville, Mr. Flight's gardener, won the chief prize for Ferns; and Mr. W. Wareham, gardener to T. C. Burnell, Esq., that for Tuberos Begonias. Mr. E. Hillier, nurseryman, had the best bouquet, and otherwise contributed effectively to the furnishing of the hall.

Collections of fruit were very good indeed, notably the first, staged by Mr. W. Allen, which contained excellent Grapes, a splendid dish of President Strawberry, a capital Blenheim Orange Melon, highly coloured Violette Hâtive Peaches, and Elruge Nectarines. Mr. Mildon, gardener to Mrs. Turner, Kings Worthy, and Mr. Inglefield followed in the order named, the Alexandra Noblesse Peaches of the former being remarkably fine, and of the latter the black Grapes and Strawberries arrested attention. In the classes for Grapes Mr. Mildon was first with Black Hamburgh, good, and Foster's Seedling, with remarkable berries; Mr. W. Allan, gardener to Sir G. Russell, Swallowfield, following with good examples, his bunches of Foster's being large and full.

Vegetables were excellent, Mr. Pope, Highclere Gardens, winning the chief prize for nine dishes with first-rate examples of Cauliflowers, Onions, Turnips, Carrots, Beans, Tomatoes, Peas, Cucumbers, and Potatoes, followed closely by Mr. Inglefield and Mr. R. Lye, The Gardens, Sydmonton Court, Newbury. There was good competition and superior

produce staged for Messrs. Sutton & Sons' prizes, which were won by Messrs. Lye, Pope, Inglefield, and Dauncey in the order named.

The Show was noteworthy by the absence of inferior exhibits, and the Winchester Horticultural Society deserves the support of the inhabitants and cultivators of the district of which the historic old city is the centre. Mr. Chaloner Shenton is the courteous Secretary of the Society.

CARLTON-IN-LINDRICK.

THE third annual Show was held on Thursday last, but owing to the lateness of the Roses and the previous stormy weather the Show was not quite up to the expectation of the Committee. Several nurserymen were unable to compete. Mr. Frettingham of Beeston was the principal prizetaker in the nurserymen's class, and Messrs. Fisher, Mallender, Western, and Machin were the prizetakers in the open amateurs' classes. Some very good blooms were shown in the cottagers' classes. The best Rose in the Show was found in Mr. Frettingham's box, a Heinrich Schultheis, a very beautiful Rose. Miss Mellish, Hodsock Priory, and H. V. Machin, Esq., Gateford Hill, each showed a collection of garden Roses.

GLOUCESTERSHIRE.

It is to me a peculiar satisfaction to be able to record a completely successful result of the zealous exertions of my friend the Rev. F. A. Burnside, for when the Moreton-in-the-Marsh Show collapsed—for there, neither would Mahomet go to the mountain nor the mountain to Mahomet—Roses were brought together, but nobody came. Seeing this I advised Mr. Burnside to try Gloucester, with the result that he and his friends set vigorously to work. They obtained promises of support from all quarters, and although the weather has been of the most damaging description, yet most certainly the best provincial show that I have as yet attended, both in the number and quality of the flowers, was that held on Tuesday last at the Corn Exchange, Gloucester. By-the-by, an amusing incident occurred to me in connection with it. I was under the impression that it was to be held at the Shire Hall, and so wended my way there. I found a considerable crowd about, but I missed the green boxes which generally mark the presence of a Rose Show. However, I went in, and up the steps, where I came to a gate closed (which I thought rather an unusual precaution). A policeman was standing by, who on my saying I wished to go in, said there was no admission. "But I am one of the Judges." Whereat X. 52 shook his head, and said that won't do, and I daresay thought me a wicked old parson for telling him such a "crammer." I then found that the assizes were going on, and that I had innocently enough passed myself off as Judge Denman. I had a good laugh, and then wended my way to the Exchange. Here all was bustle and hurry of the right sort, boxes in all directions, a "hurrying to and fro," and excitement all round. The room was an excellent one, with a capital overhead light, and the flowers looked well; and although one is accustomed to see what can be done by Rose growers under the most adverse circumstances, I was utterly unprepared for the cleanliness and freshness of the blooms. One exhibitor, who muleches his beds, and thus saves them a good deal from the splashing caused by heavy rain, yet said that some of his blooms, 21 inches from the ground, were covered with mud, while hailstorms knocked others to pieces, but withal, both nurserymen and amateurs showed in excellent form.

Seldom has there been a keener competition than in the class for forty-eight blooms, nurserymen. There were six stands set up, and five out of the six ran very close upon one another, the first prize being ultimately awarded to Mr. Frank Cant of Colchester with a very fine stand of the following flowers:—Madame Marie Finger, Horace Vernet, Her Majesty, Earl of Dufferin, Captain Christy, François Michelin, Pride of Waltham, Etienne Levet, Catherine Mermet, Louis Van Houtte, Duke of Teck, Ulrich Brunner, Niphotos, Général Jacqueminot, Maréchal Niel, Sultan of Zanzibar, Madame Gabriel Luizet, Violette Bouyer, Prince Camille de Rohan, Madame de Watteville, Duke of Edinburgh, Madame Lambard, Mary Bennett, Earl of Pembroke, Merveille de Lyon, A. K. Williams, Madame Cusin, Exposition de Brie, Souvenir d'un Ami, John Bright, Rubens, Fisher Holmes, Madame Isaac Pereire, Dr. Andry, Viscountess Folkestone, Camille Bernardin, Grace Darling, Beauty of Waltham, Marguerite de Roman, Rosieriste Jacobs, Mrs. Baker, Marie Verdier, Madame Alphonse Lavallée, Victor Hugo (a magnificent bloom of a grand new Rose), and Souvenir d'Elise. Messrs. Paul & Son were second, and Mr. B. R. Cant third. In the class for twenty-four trebles Messrs. Paul & Son were first with a good stand of Captain Christy, Etienne Levet, Madame Bernardin, Marshal P. Wilder (very like Alfred Colomb), E. Y. Teas, Her Majesty, Ulrich Brunner, Heinrich Schultheis, Duke of Edinburgh, Général Jacqueminot, Madame Eugène Verdier, Alfred Colomb, Sénateur Vaisse, Duchesse de Morny, François Michelin, Charles Lefebvre, Niphotos, Prince Camille de Rohan, Pride of Waltham, Marie Baumann, La France, and Mrs. John Laing. Mr. B. R. Cant was second, and Mr. F. Cant third. In the class for twenty-four Messrs. W. J. Jefferies & Son of Cirencester were first with Ferdinand Chaffolte, François Michelin, Duke of Edinburgh, La France, Madame H. Jamain, Comtesse Tretiakoff, Madame Eugène Verdier, Mary Pochin (very pretty), Merveille de Lyon, Etienne Levet, Madame Gabriel Luizet, Comte Raimbaud (which has been shown very fine this season), Elie Morel, Earl of Pembroke, Richard A. Sutton (a Rose I do not know, but I believe a seedling of Frettingham's), Queen of Queens, E. Y. Teas, Lady Mary Fitzwilliam, Madame Charles Wood, Jean Ducher, Rosieriste Jacobs, and Marie Verdier. For the best twelve of any one kind, double, Mr. B. R. Cant was first with A. K. Williams, Mr. Frank Cant second with Louis Van Houtte, and Messrs. Paul & Son third with Marie Baumann. For the

best twelve blooms of any sort, Mr. B. R. Cant was first with Merveille de Lyon, Messrs. Paul & Son second with La France, and Mr. Cranston third with Merveille de Lyon.

In the amateurs' classes Mr. W. G. Grant of Ledbury took the leading position. His stand of twenty-four was an excellent one, much in advance of the forty-eight he showed at the Crystal Palace. It comprised fine blooms of Marie Baumann, Charles Lefebvre, Heinrich Schultheis, Sénateur Vaisse, La France, Général Jacqueminot, Mrs. John Laing, Etienne Levet, Duchesse de Morny, Duke of Edinburgh, Souvenir d'un Ami, Horace Vernet, Madame Gabriel Luizet, A. K. Williams, François Michelin, Comte Raimbaud, Marie Verdier, Duchess of Bedford, Baroness Rothschild, Dr. Andry, Le Rhone, and Merveille de Lyon. Mr. T. B. Hall of Larkwood, Rockferry, was second. Mr. Grant was again first for twelve trebles, showing fine blooms of Ulrich Brunner, Etienne Levet, La France, Louis Van Houtte, Madame Gabriel Luizet, Général Jacqueminot (very fine), François Michelin, Merveille de Lyon, Duke of Edinburgh, Dupuy Jamain, and Madame Eugène Verdier. Dr. Budd of Bath was second, and Mr. T. B. Hall third.

In the Tea and Noisette some good stands were set up, although many of the blooms had suffered from the bad weather. In the nurserymen's division for eighteen Teas or Noisettes, Mr. Geo. Prince was first with some of his usually fine blooms, consisting of Catherine Mermet, Hon. Edith Gifford, Souvenir d'un Ami, Alba Rosea, Comtesse de Nadaillac, Niphotos, Jean Ducher, Rubens, Innocente Pirola, Marie Van Houtte, Madame Cusin, Souvenir de Sarah Prince, a white sport of Souvenir d'un Ami, and named in remembrance of one whose memory many rosarians cherish; Francisca Kruger, Madame Caroline Kuster, Madame de Watteville, and The Bride. Mr. Frank Cant was second, and Mr. B. R. Cant third. For the best twelve Messrs. Jefferies & Son were first with Madame Lambard, Rubens, Souvenir d'un Ami, Niphotos, Perle des Jardins, Princess of Wales, Sunset, Maréchal Niel, Catherine Mermet, Madame Cusin, and the Hon. Edith Gifford.

In the amateurs' class, Mr. W. G. Grant was again first for the best eighteen, with a fine box containing Rubens, Souvenir d'un Ami, Souvenir d'Elise Varden, Madame de Watteville, Madame Cusin, Maréchal Niel, Madame Lambard, Madame Caroline Kuster, Francisca Kruger, Hon. Edith Gifford, Comtesse de Nadaillac, Anna Ollivier, Amazone, Souvenir de Thérèse Levet, Souvenir de Paul Neyron, and Devonensis. The Rev. F. R. Burnside was second for the best twelve. Mr. W. G. Grant was again first with Souvenir d'un Ami, Souvenir d'Elise Varden, Madame Lambard, Niphotos, Comtesse de Nadaillac, Rubens, Souvenir de Thérèse Levet, Marie Van Houtte, Madame Cusin, Amazone, and Madame Caroline Kuster. Mr. E. Claxton was second, and the Rev. F. R. Burnside third. For six blooms of any one Tea or Noisette, Mr. W. G. Grant was first with Souvenir d'un Ami, Mr. Claxton second with Alba Rosea, and Dr. Budd third with Francisca Kruger.

The success which has attended this first show both florally and financially will no doubt encourage its promoters to go on and prosper. It is in good hands, and despite the gloomy anticipations of some it was an undoubted success. I shall ever remember it, for it was the occasion of my meeting one whom I had never seen since we formed two of a very happy party who went to the Eglinton tournament in 1839—nearly fifty years ago.—D., Deal.

BEDFORD AND BEDFORDSHIRE HORTICULTURAL SOCIETY.

THE annual Show of this Society was held on Wednesday last in the New Park, Bedford, on which day the park and the new suspension bridge over the Ouse were opened by the Marquis of Tavistock, and in the evening an illuminated river fête took place. The weather, however, on this Bedford red letter day will long be memorable as probably the most unseasonable July day of the century. The Show was a very extensive one, and although Roses constituted only comparatively a small part of the extensive display, they are annually becoming a most important feature here, and a large tent had this year to be devoted to them, as there are open classes in this department also for cut herbaceous flowers and stove and greenhouse plants.

In the open class for nine stove and greenhouse plants, not less than six in bloom, there were two competitors—Mr. J. F. Mould of Pewsey, Wilts, who secured the first prize with well grown plants, including a fine *Cycas revoluta*, *Dracophyllum gracile*, *Cocos*, *Eriacas*, *Statice profusa*, *Vincas*, and *Hedera fuchsoides*; and Mr. H. James of Lower Norwood, who was second with a grand *Latania borbonica* and several fine but less regularly matched plants. In the division open to amateurs and gentlemen's gardeners (locally), Mr. C. Ellis, gardener to Mr. Lethbridge, Pemberley, Bedford, was first for a group not exceeding 60 square feet, his space being closely and richly furnished. Mr. Waller, gardener to James Howard, Esq., Clapham Park, Bedford, being second with a fine but lighter display; Mr. Robinson, gardener to F. Howard, Esq., Abbey Close, Bedford, following close for third place, and Mr. R. Day, gardener to Joshua Hawkins, Esq., Mayor of Bedford, came fourth. For six foliage plants in the same division Mr. G. Vyne, gardener to C. Franklin, Esq., Bedford, was first, and Mr. Robinson second. Fuchsias were well shown in this division, Mr. W. Galloway, gardener to Miss Rice-Trevor, Bromham Hall, and Mr. Robinson having each six large well-trained specimens in good bloom, and were placed respectively first and second.

Roses in the open classes were well represented, the blooms throughout the Show being above the average of exhibits held during this variable weather, the colours of the H.P.'s bright, and the winning stand of forty-eight Roses from Mr. F. Cant of Colchester was in keeping with his previous displays this season. There were no less than eleven

entries in this class despite the weather, Mr. F. Cant of Colchester leading with grand blooms of Madame G. Luizet, A. K. Williams, François Michelin and Ulrich Brunner, both striking flowers; Victor Hugo and Pride of Reigate also good; Beauty of Waltham, Louis Van Houtte, Marie Verdier, Marie Baumann, Merveille de Lyon, Souvenir d'Elise, Horace Vernet, Jules Finger, Dupuy Jamain, Grand Mogul, Heinrich Schultheis, Rosieriste Jacobs, Annie Laxton, Dr. Andry, The Bride, Souvenir d'un Ami, Viscountess Folkestone, Dr. Sewell, Etienne Levet, Catherine Mermet, Duke of Edinburgh, Madame Ducher, Marie Finger, and Ferdinand de Lesseps, &c. Messrs. G. & W. H. Burch, Peterborough, had also fine flowers and obtained second place, A. K. Williams, J. S. Mill, Madame Eugène Verdier, Heinrich Schultheis, Niphotos, Xavier Olibo, Rubens, Duc de Rohan, Duchess of Bedford, and Mdlle. Marguerite Dombrian being the most conspicuous. Mr. W. H. Frettingham, Beeston, Notts, also showed well and secured third prize.

For eighteen Teas in the class open to all Mr. F. Cant, who was first, had some wonderfully clean blooms, including very fine Souvenir d'Elise, Jules Finger, Madame Cusin Rubens, Madame Lambard, Madame de Watteville, Souvenir d'un Ami, Souvenir de Paul Neyron, Maréchal Niel, The Bride, Catherine Mermet, Adam, and Devonensis. Mr. J. Mattock, Headington, Oxon, was second, and Messrs. Burch third.

For twenty-four Roses in the open class for amateurs Mr. W. H. Lindsell of Hitchin was in fine form, having in his winning stand superb blooms of La France, Princess of Wales, Annie Wood, Maréchal Niel, Louis Van Houtte, François Michelin, Horace Vernet, and Her Majesty. The Rev. J. H. Pemberton, Havering-atte-Bower, coming second; Marquise de Castellane, A. K. Williams, E. Y. Teas, Madame G. Luizet, Horace Vernet, Mrs. Baker, and Countess of Rosebery being the best of a very good stand. Mr. J. L. Curtis of Chatteris, came third, and his blooms as seen in the after part of the day were well sustained, and would not then have discredited an award of first. He had a remarkable bloom of Olivier Delhomme, Her Majesty, Etienne Levet, Marie Baumann, Niphotos, Baron A. de Rothschild, and Madame C. Crapelet in excellent form.

For twelve Roses, open to all amateurs, Mr. E. Mawley, Berkhamstead, was first; Mr. W. O. Times, Hitchin, second; and the Rev. F. H. Gall, Hitchin, third. For twelve Teas and Noisettes in the same division, Mr. Lindsell was first with very fine blooms, Jean Ducher, Niphotos, Souvenir d'un Ami, Rubens, Comtesse de Nadaillac, Amazone, Catherine Mermet, and Maréchal Niel being particularly good. The Rev. W. H. Jackson, Stagsden Vicarage, Bedford, who had what in an ordinary contest would have been a winning stand, was placed second, having grand flowers of Belle Lyonnaise, Madame Thérèse Levet, Madame Lambard, Amazone, Innocente Pirola, and Souvenir d'Elise; Mr. J. L. Curtis coming third. In the local amateurs' classes for twenty-four cut Roses and for twelve Teas and Noisettes Mr. Jackson was again first, and for twelve cut Roses Mr. G. Dyer, gardener to G. W. Repton, Esq., Odell Castle, Beds, took the lead. In the class open to all England for thirty-six bunches of cut hardy herbaceous or bulbous flowers there was a good display; Messrs. Paul & Son of The Old Nurseries, Cheshunt leading with large and striking masses of blooms, the following being especially attractive—viz., *Epilobium angustifolium* album, *Tropæolum polyphyllum*, *Delphinium grandiflorum* plenum *Le Vésuve*, *Chrysanthemum maximum*, *Tritoma caulescens*, a very bold flower, and the earliest of the race; *Potentilla* Wm. Robinson, *Alstrœmeria aurea*, *Orchis foliosa*, and *Erigeron speciosus* superbus. Messrs. Burrell & Co. Howe House Nurseries, Cambridge, also made a grand show, and secured second prize, *Iris Anglica*, *Horatius*, *Queen of Lilacs*, and *Madame Patti* being very striking varieties; *Centaurea montana* rubra, *Achillea millefolium* rosea, *Astrantia major*, *Papaver nudicaule* miniatum, deep orange, and *Lilium Thunbergianum* Prince of Orange were also staged in very showy masses. Mrs. E. Horton, Bedford, was third with a most creditable stand. Messrs. Laxton Bros., Bedford, also showed a large collection, not for competition, including some fine Clove-like seedlings from Mrs. Sinkins Pink, and remarkably bright and distinct *Gaillardia grandiflora* in variety.

There was a considerable show of locally grown fruit, but the want of sunlight and recent low temperature had evidently made itself apparent, the Grapes especially showing want of colour and finish. For a basket of fruit, six kinds, Mr. Ellis was first, Mr. Day second, and Mr. Galloway third. Mr. Galloway was first for two bunches of black Grapes and for Melons. Mr. W. Allis, gardener to Major Shuttleworth, Old Warden, Beds, was first for six Peaches and for three varieties of Strawberries, consisting of well-ripened fruits of Amateur, Captain, and President, Mr. Dyer being first for a single dish of Sir Joseph Paxton. Vegetables were a very large and good feature at the Show. For a collection of twelve fruits in the leading amateurs' class Mr. Waller was first with an excellent stand; Mr. Musgrave, gardener to A. D. Chapman, Esq., Milton Ernest Hall, Beds, second; Mr. Ellis third, and Mr. Vyne fourth. In the competition for prizes offered by Messrs. Sutton & Sons, Reading, Mr. Musgrave was first; Mr. Herman, gardener to Griffith Jones, Esq., Goldington Bury, Beds, second; Mr. Allis third, and Mr. Robinson fourth. For a collection of six varieties of Potatoes Mr. Waller took the lead, Mr. Robinson was second, and Mr. Vyne third. For a basket of salad, six varieties, Mr. Waller was again first, Mr. Robinson second, and Mr. Vyne third. Neither Potatoes nor Peas were shown of their usual size and quality, and it was noticeable that the large-podded sorts of Peas were generally badly filled and had to give place to those of the Filbasket type, which appears to be particularly good this season.

Amongst the miscellaneous exhibits Messrs. E. & F. Newton, Horti-

cultural Builders, Hitchin, showed specimens of their patent system of glazing without putty, which has been tested and approved by a sub-Committee of the Royal Horticultural Society; and Mr. W. Day of Bedford also exhibited specimens of his useful and simple patent plant trainer.

CHISWICK SHOW.

JULY 12TH.

THIS vigorous Society held its Summer Show in the Gardens of the Royal Horticultural Society at Chiswick on Thursday last, the 12th inst., and though the weather was far from favourable, there was a cessation of rain for a period during the afternoon which enabled many persons to visit the exceedingly attractive and varied Exhibition. Three large tents were occupied with groups, flowers, and cottagers' productions. The conservatory also was nearly filled with more delicate plants, fruit, and vegetables, the quality throughout being of a high character. The arrangements were good, and creditable alike to the Hon. Secretary, Mr. Joseph Fromow, and his willing assistants.

The special interest of the Show centred in the groups of plants arranged for effect (100 square feet) in which class the first prize was a Jubilee challenge cup, value 20 guineas, presented by Mrs. S. A. Lec, and a money prize of £4. The cup is to become the absolute property of the exhibitor who wins it three times, not necessarily in succession, and as Mr. W. Brown of St. Mary's Grove Nursery, Richmond, won it last year in a keen competition, many were interested in learning whether he would retain the prize this season. There were only three competitors, but two of these—namely, last year's winner and Messrs. Hooper & Co., Covent Garden, contributed two such beautiful and evenly balanced groups that it became rather doubtful which would be successful. There were very few points to choose between them, but ultimately the Judges gave a generally approved decision in Mr. Brown's favour, who has thus but one more victory to achieve to fulfil the somewhat arduous terms of the class. The winning group was faultless, and as it deserves more attention than can be given in this report, it is described at length on page 42, together with that for which Messrs. Hooper & Co. secured the second prize, and that from Mr. J. Fromow, Sutton Court Nursery, Chiswick. There was also a class for smaller groups (60 square feet), and in this H. J. Atkinson, Esq., Gunnersbury House (gardener, Mr. Hudson), was first, winning the Royal Horticultural Society's silver medal and money prize. The group was a well-finished and graceful one, Crotons, Palms, Dracænas, and Ferns forming the principal foliage plants, with them being associated a few *Eucharises*, *Liliums*, and *Cattleyas*, margined with *Gloxinias*, *Adiantums*, *Cyrtodeira fulgida* and *Panicum*. E. H. Watts, Esq., Devonhurst (gardener, Mr. A. Wright), was second with a bright arrangement of *Kalosanthes*, *Gloxinias*, and *Odontoglossum vexillarium* edged with *Panicum* and *Caladium argyrites*.

Stove and greenhouse plants were well shown by Mr. Bates, Poulett Lodge Gardens, Twickenham, who won first honours for six specimens, H. Little, Esq., having the best three specimens, and Mr. Chadwick the leading six fine-foliage plants. Mr. H. Little was also a successful exhibitor of Tuberous Begonias, Pelargoniums, and Orchids, being followed in the last named class by Messrs. Cowley and Prewett. Fuchsias, Caladiums, Coleuses, and other plants were fairly represented from several exhibitors. The non-competing exhibits of plants were numerous. Messrs. Rothschild, Gunnersbury Park, Aeton (gardener, Mr. Roberts), had an extensive and effective group. The Marquis of Bute, Chiswick House (gardener, Mr. May), also had a tasteful arrangement of plants. Messrs. J. Veitch & Sons, Chelsea; B. S. Williams, Upper Holloway; Lee & Son, Hammersmith; Rumsey, Waltham Cross; Hooper & Co., Covent Garden; and C. Turner, Slough, similarly contributing groups of plants and collections of Rose blooms.

Prizes were offered by the Duke of Devonshire for the best three stands or vases of flowers and foliage for the dinner table, and first honours were accorded to Mrs. Hudson for a very graceful arrangement. Tall single slender trumpets rose from a dish at the base, the stems wreathed with Asparagus, the top lightly filled with white and red *Rhodanthes* with a small stem or two of the bright red *Chelone barbata* and *Adiantums*, *A. caudatum* drooping round the edge, the base being filled with large and handsome white Water Lilies, a few sprays of *Nemophila insignis*, red Rose shoots, a few *Cattleyas* and nodding *Brizas*. Mr. J. Prewett was second with pleasing stands that were much admired. Mr. Chadwick was third, a preponderance of white flowers rendering his stands rather dull. For three bouquets Mr. Prewett was first, followed by Mr. Gardiner and Mrs. Mott. Buttonholes were well represented, an exceedingly handsome basket of Roses gained Miss S. A. Fromow the first prize in that class.

In the fruit classes Mr. Bates won first honours for six dishes, comprising Foster's Seedling and Alicante Grapes, Lord Napier Nectarine, a good Queen Pine Apple, President Strawberries, and Stirling Castle Peaches. L. J. Baker, Esq., Ottershaw Park, Chertsey (gardener, Mr. Osman), and Mr. C. J. Waite, Glenhurst Gardens, Esher, were the other two prizetakers in the order named. Messrs. Osman, Milsom, Bates, and Radley were the winners in the class for black and white Grapes; Mr. W. Palmer leading for two dishes of Strawberries with Auguste Nicaise and President, both fine, but the former especially so. Mr. Waite was as usual very successful in the vegetable classes, both for the prizes provided by the Society and those offered by Messrs. J. Carter & Co. Messrs. Sutton & Sons also offered prizes for Tomatoes, which brought several competitors, and the cottagers' classes were well filled.

OSTROWSKIA MAGNIFICA.

NOVELTIES so distinct in character as the beautiful plant recently exhibited under the above peculiar generic name by Messrs. J. Veitch

upon the plant, and except to a few specialists amongst hardy flowers, who watch the continental works and catalogues closely for novelties, the name will, like the plant, be a total stranger at present. It is not

FIG. 6.—OSTROWSKIA MAGNIFICA.

and Sons of Chelsea are rarely seen, and quite a little crowd of admirers gathered round the box containing the specimens at the Westminster Drill Hall on the 11th inst. Gardeners will search in vain in their Paxton's or Johnson's Dictionaries for the Russian-looking title bestowed

likely to remain so long, as the gigantic campanulaceous flowers are followed by proportionately huge pods of seed, and stock will in a season or two be abundant enough. Even now it seems that though the plant has only been in the hands of the nurserymen for a comparatively

brief time, it is sufficiently cheap to be catalogued in continental trade lists, and it will soon appear in those published in this country.

The plants exhibited at Westminster were certificated, and Messrs. Veitch stated that it was a native of Central Asia, whence it appears seed was sent to Russia and Germany, and it was received in England through Max Leichtlin of Baden. It is a perennial, and said to be quite hardy, the plants grown by Messrs. Veitch being the first to flower in this country. The flowers are somewhat suggestive of *Campanula macrostyla*, the corolla shallow, 5 or 6 inches across, with seven or eight roundish lobes. The colour in the specimens shown was a soft mauve with slightly darker veins, but we believe that when described in the "Gartenflora" last year the colour was referred to as "dark blue." Probably it will vary from seed in the same way that other allied plants do. The stems are strong, 4 or 5 feet high, with oblong leaves arranged in whorls of four or more, and the flowers are borne either singly or in terminal racemes. It is unquestionably a noble and handsome plant, and as there is little doubt that it will prove as hardy as it is claimed to be, it may be expected to become a favourite in gardens.

ARTIFICIAL MANURES.

I CAN readily understand Mr. Coombe's disappointment after reading my recent contribution to the above subject. This he has by some ingenious means persuaded himself has been brought about by my sudden opposition to the use of "properly proportioned combinations." Now, I consider my opposition to the use of these fancy mixtures, as advocated by my too scientific friend, is by no means hidden—on the contrary, has been consistent throughout this discussion. Is it not possible that the enthusiasm of my opponent has been slightly checked by the arguments I have brought forward, and the hard facts that I have opposed to his pet theory? This view of the case is materially strengthened by the cautious way in which he has evaded many of my arguments, and, with one exception, he has refrained from replying to any of those in my last article. It has suited him better to take a hasty survey of the discussion, with the result that his fertile imagination has enabled him to conjure up a host of modes, practices, or systems championed by me at various stages of this discussion, whereas I have advocated but one—that of changing the food supplied to plants, according to the various stages of growth that they pass through and the changing circumstances by which they are surrounded. As I am by no means anxious to evade any portion of the arguments contained in his contributions, but I am rather glad to have so good an opportunity of confronting some of his erratic statements and impracticable theories. I think it my duty to take each paragraph as it stands, supply his omissions, and endeavour to find out where my opponent discovers the subtle distinctions he draws when enumerating the many systems he contends I have advocated.

The first is defined by my enlightened opponent as the "haphazard" one; the next, the "semi-artificial system," taking its name, we are told, from the faulty artificial manure being supplemented by natural liquid and solid manures. Now, the "haphazard system" may be considered a myth, as I have previously shown that the system of giving plants such changes of food as are known to produce good results cannot be a haphazard one. The "semi-artificial system" is rightly named, as it is the practice of giving plants the various changes of food advocated throughout, and not put forward after his first criticism, as Mr. Coombe asserts. In my original article I advised the use of artificial manures to be supplemented by the use of natural liquid manure. I still do so, not only as a matter of utility, but of economy also, as it should be the aim of all cultivators to turn to account the food contained in soil and in the natural manures at their disposal. As to calling up the names of successful cultivators to bolster up my cause, I ask Mr. Coombe what more effectual bolstering up could be given than by showing that the greatest horticultural achievements of modern times have been produced by the system he vigorously condemns? Surely he will admit that, no matter by what names successful practices are called, they will be generally accepted as the correct ones.

By some philosophical mode of reasoning, hitherto unexplained, my opponent next sees the "fad" and "experimental systems" unfolded. Now, if he can see the slightest difference between these two and the "semi-artificial system," I venture to assert his sagacity is more acute than that of the majority of readers. It all amounts to giving plants the changes of food I have advocated. But to show Mr. Coombe that he had not all the science on his side, I brought to his notice a few facts, which showed the system was compatible with theory in its best form, and while upholding the great usefulness of scientific knowledge in the manufacture and use of manures, showing that these "nicely proportioned combinations" are not necessary in practice provided the really important elements are present. The exact quantities of these can only be determined accurately by analysing all soils used, and that is, I think my opponent will admit, quite out of the question at present. If in the future sufficient scientific knowledge be acquired, and the means provided for gardeners to perform this operation, it would be rather a cumbersome and expensive system to reduce to practice, except for growing specialities on a large scale, and then comes the question. After all this scientific knowledge, would the results produced be as enthusiasts

fancy? Would they pay their way? This I am willing to leave an open question.

I am not so much mystified as my adversary seems to imagine about the "chemical compounds" in themselves, but I am in total darkness as to how he would put his vague theories into practice, and I would suggest that in some future contribution Mr. Coombe will favour us with more definite information on that point. It cannot fail to be both interesting and instructive. When contemplating this subject in all its intricate bearings, I am led to think of my opponent, during the busy spring months, when the numerous occupants of greenhouses and plant stoves require potting, compounding his soils according to the p.p.c. system for potting the various plants that differ so widely in the elements of which they are composed. I can picture him measuring out, in the minutest proportions, the various earths, alkalies, acids, and salts, and mixing the ingredients into numerous heaps in readiness for the special subjects to be dealt with. After this troublesome part of the task is completed I venture to assert that the scene of these operations would present a spectacle hitherto unknown to the horticultural world. The plants are duly potted into this precious compound, and all goes on right for a time, but a suspicion gradually dawns upon the mind of my opponent that they are not making the progress they should do after so satisfactory a start on scientific principles; this puzzles him not a little, as he knows that he gave each the proper amount of potash, acids, phosphates, and ammoniacal and nitrogenous manures. Not being able to analyse the natural ingredients used, he was obliged to resort to the haphazard practice of either guessing at the amount of certain necessary elements the soils contained without the addition of other natural or artificial substances, or add a properly proportioned combination of the elements needed for the plants' support in an artificial state, without any regard for the quantities already in the soil. This must, of course, throw the combination altogether out of its proper proportion. But we will be charitable enough to suppose the disarrangement thus brought about was not enough in itself to produce very unsatisfactory effect upon the growth of the plants, yet still they do not progress so well as they should do. Being possessed of a laudable determination to find out some cogent reason why this is so Mr. Coombe has samples of his soils analysed, and in many cases he finds them altogether deficient in nitrogenous manures, although he gave them a properly proportioned quantity in the first instance; but, unfortunately, he had overlooked the fact that in giving plants artificial manures in a soluble form he places the whole quantity at their disposal, so that they could assimilate an unlimited quantity so long as it remained within their reach. Under these conditions the development of plant is regulated by the quantity of phosphoric acid, potash, &c., taken up daily, and also by the amount of warmth, light, and moisture brought to bear upon them. Now the case is quite different when the soil contains a sufficient quantity of nitrogen in an organic and insoluble form. From this store of nitrogen the soil prepares a little nitric acid daily, and regularly feeds the plant with a small quantity of soluble nitrogen.

This accounts for their behaviour under the circumstances above given. The soluble nitrogen being rapidly exhausted, and no further supply was within reach, hence the slow and unsatisfactory progress of the plants. It also shows clearly that the proper course to pursue is to combine certain parts of plant food together, and administer nitrogenous manures at various stages of their growth, according to the changing circumstances of each particular season, and when the sound practical judgment and didactic faculty of the cultivator shall show him they stand in need of it. And I maintain that by these means the highest results are obtainable from the resources at our command. It is on these lines that I consider scientific knowledge will lead to future advancement rather than aiming at such nicely proportioned combinations. The subject must be treated on broad lines rather than in petty adjustments. Pay particular attention to the important elements by which the growth of plants are built up until it can be clearly shown that these theories are necessary, and also that they can be reduced to a practical system, having advantages over those already practised. Now my opponent has advanced no argument whatever against my previous statement that while certain elements are absorbed by the soil, and only given up again in small quantities, while others remain freely moveable, and a residue not quickly taken up by the plant would be wasted. This in itself is sufficient to show the advantages of supplying manures in the way I have advocated. Neither has he challenged the statement that it is as yet quite unknown why a given crop sometimes takes up a much larger per-centage of soluble substances put into the soil.

All these interesting facts will well repay the careful consideration of Mr. Coombe before he can claim to be acting on lines so superior to those that have produced results which as yet scientific knowledge cannot surpass. In his enthusiasm he has also overlooked another trifling fact which I brought before him when stating in my last article that I failed to find a single instance in which he had taken into consideration the various stages of growth that plants pass through. This is to be regretted, as a study of chemistry, spasmodical or otherwise, shows how important the point is.

Returning to the lime question, my thanks are due to your correspondent for reminding me I have not yet cleared up the point in reference to its action on soils in regard to the idea of its causing moisture to be retained in land that it had been applied to with the object of renovating its fertility. This is no new idea, but has been taken advantage of by cultivators for grass, and in "Parke's Chemistry" the following explanation is given:—"When quicklime is spread upon land it destroys its causticity, the organisation of all animal and

vegetable matters remaining in the soil, and thus renders them a fit pabulum for the future crop. In like manner the lime would also burn up the tender shoots of fresh plants and sterilise instead of fructifying the ground; but Nature has so ordered it that as the lime falls to powder on the land it should gradually absorb carbonic acid from the atmosphere, which deprives it of its causticity and converts it into chalk. Hence lime and chalk are particularly useful on sandy soils." It is also an acknowledged fact that chalk when applied to heavy soils makes them less retentive of moisture, and light sandy soils more retentive.

Concerning the explanation advanced as to why plants of *Erica hyemalis* so frequently become candidates for the rubbish heap when they pass from the hand of the market grower, while those retained by those growers do not share the same fate. This explanation scarcely goes far enough. Granted that the flowers on the plants kept in the market growers' hands would be cut while in full beauty, while those in private establishments would not be cut back till the flowers faded, that might give those first named the chance of making stronger growth, but would not be sufficient to account for one set of plants dying while the others were making splendid growths. Neither does it show that the bulk of phosphoric and potassic constituents would have become absorbed by the vigorous growth promoted by the use of nitrate of soda, as we have kept plants in the same pots for two years without their showing any diminution of energy, although no other stimulant but nitrate of soda was used. But in the case of the market grower's plants they would be repotted to make larger specimens, and consequently have a fresh supply of the elements above mentioned in the soil. My answers to the questions at issue, as summed up by Mr. Coombe, I will give in as few words as possible. In reply to the query, Is a change of food necessary for plants? I think my arguments serve to show that if not absolutely necessary it enables us to produce the best results by turning the natural resources at our command to the most profitable use in a simple and practical manner, according to the varying stages of growth that plants pass through. As to the possibility of producing a perfect plant food, I consider it may be accomplished in exceptional cases, but would be too expensive a system to become general for all classes of plants. Thirdly, Will experience triumph over science? My firm conviction on this point is that they are dependent upon each other. Together they will help forward the march of gardening, and achieve the future triumphs of the horticultural world; and my concluding advice to my "scientific opponent," finds ready expression in the grand old motto, "Be just before you are generous." Do not let your generous enthusiasm for science lead you to deny to practical experience the just share of honour it must ever claim in the future achievements of gardening.—H. DUNKIN.

VEGETABLES FOR EXHIBITION.

TOMATOES.

THERE is no necessity to enlarge upon the merits of a good dish of Tomatoes and the weight it has in either a large or small collection of vegetables, as few need to be told how much judges are influenced by them. What we have to consider is how they may be produced in perfection when most wanted. Some seasons, such for instance as those of 1886 and 1887, very good fruits may be had late in July and during August from plants in the open air; but as a rule these ought not to be wholly depended upon, or the dish of prize fruits may not be forthcoming. At this time of year, or say from May to September inclusive, there is in numerous gardens a certain amount of house room that might well be devoted to the culture of Tomatoes. I do not assert that they are absolutely safe under glass, as of late years a disease known as *Cladysporium fulvum* has developed, proving even more destructive among house grown crops than even the better known Potato disease in the case of those grown in the open air. As a rule, however, the handsomest and best coloured fruits are obtained from plants under glass, and it is to the cultivation of these I shall principally devote this paper.

Forcing houses or high temperatures are not needed, Tomatoes doing better during the summer months in warm or sunny greenhouses, fruit houses, or pits and frames. Supposing the first dish is wanted early in July the seed should have been sown early in March, a month later being quite soon enough when the fruit is most needed during August. Being continuous bearing there is no harm done if the plants mature a few fruits before they are needed, but the first clusters are generally the finest, and we try to time these for the shows. Seed should be sown thinly and set in gentle heat to germinate. When the seedlings are in rough leaf they ought to be placed near the glass, and also thinned if need be, the aim being to keep them as sturdy as possible. First place them either singly in 5-inch pots or in pairs in 6-inch pots, using light loamy soil, and sinking the seedlings up to the seed leaves. Fine strongly rooted plants ought to be the result, and these require to be shifted into their fruiting quarters before they become badly root-bound. Whether they shall be fruited in large pots, tubs, boxes, or planted out must depend upon circumstances. Either of the former plans is suitable for greenhouse stagings, tubs or boxes, though rather unsightly, being, however, preferable as affording

more root room and not requiring such frequent attention in watering.

When planted out the roots ought to be confined to a rather narrow border or ridge of soil, or otherwise the top growth is apt to be much too vigorous. To obviate the latter difficulty we usually place our plants in 12-inch pots, and set these on the borders. The roots soon spread into the soil underneath, but not to such an extent as to defeat the object in view. This plan is to be specially commended where the blank spaces on the walls and front trellises of Peach houses are utilised for Tomato culture, in which positions remarkably fine crops of fruit are frequently obtained. It is also advisable in the case of plants grown in pits in succession to Potatoes, Beans, or other crops, and which are to be trained over temporary trellises. A compost most suitable for Tomatoes consists of two parts of turfy loam roughly chopped up to one of old Mushroom bed manure, or some substitute for the latter, but any good loamy soil answers well. When first placed in either lightly drained pots, tubs, or boxes these should only be about three parts filled with soil, this allowing space for a good top-dressing of rich compost later on, or when the first clusters of fruit are set.

Much of the foregoing advice is offered too late to be of any real service this season, and I shall endeavour to remedy this somewhat by advising more fully upon the treatment of plants as they now are in many gardens, reserving comments upon the November crops for a separate paper. Overcrowding is one of the most frequent causes of failure, this being brought about either by planting too thickly, or by allowing much superfluous growth to form. The consequence of crowding in any way is weakly flowers and a poor set, and it often happens fewer plants or leading growths would have given much finer crops of fruit. I prefer training each plant to a single stem, or what is known as the single cordon system, and every strong plant in single rows may well be not less than 15 inches apart—this whether staked uprightly or trained up a roof, trellis, or wires. Such should have all side shoots cut or rubbed out as fast as they form, the lead only being unstopped. Thus treated, a series of strong bunches of bloom forms, this being followed by clusters of fine fruits. Where there is plenty of wall or roof space to be covered single plants may be allowed to form several leads, a distance of 12 inches dividing each reserved shoot, these to have all side shoots rubbed out as often as necessary. We have taken extra good crops from plants in pots set on a fruit border and trained thinly over a front trellis, and also from others rooting in boxes and set on a greenhouse stage. Not only is it necessary to keep all leading growths free of side shoots, which, if left for a few days even, much weaken the main stems, but it is also advisable in the case of very robust plants to either cut away some of the leaves, or to reduce their size somewhat. When growing strongly, as most Tomato plants now are, they require almost daily attention in the way of stopping and training, and a week's neglect may much injure them.

With many it is found a difficult matter to effect a good set, especially in the early part of the season. When, however, the plants receive abundance of room, sunshine, and air, plenty of pollen is formed, and this, being dry before midday, may be distributed by smartly tapping the stems or trellises, or the syringe may be employed for a similar purpose. Most varieties are apt to form one very large fasciated bloom, this, when reserved, taking the lead and much weakening the rest of the flowers that not unfrequently fall prematurely. Seeing that these ugly flowers are invariably followed by coarse and monstrous fruits, it is unwise to leave them on the plant, as large and handsome, and not rough misformed fruit, are required for exhibition purposes. Pinch them off as soon as detected, and the other well-formed flowers will soon be benefited thereby, and a cluster of perfectly formed fruit be the result. Two or three fruit in one cluster are usually ample, and early thinning should be resorted to.

A few other details yet remain to be briefly touched upon, top-dressing being one of the most important of them, no other plant being more quickly benefited by a timely addition to the surface soil. It is most needed when plants in pots or boxes have set their first fruit, while any, whether the plants or young or old, that are rooting in a small ridge of soil ought also to be top-dressed directly they give signs of partial exhaustion. The old soil underneath being kept properly moistened without much regard being paid to the state of the fresh compost, the roots quickly take possession of the latter, and a marked improvement in the appearance of the plants will soon be visible. Apparently worn-out plants may be quickly renovated with the aid of surface dressings, and be made to produce a good crop of handsome fruit. When growing strongly Tomatoes require plenty of water, and those well set with fruit should also have liquid manure frequently. Either farmyard, liquid manure, or any of the advertised artificial manures, are suit-

able, these being applied at the rate recommended by the vendors. Superphosphate is a very safe and good manure, this being mixed with the top-dressing compost at the rate of an 8-inch potful to two bushels of soil, or it may be frequently sprinkled on the surface of the soil and washed in gradually. The smooth round-fruited varieties are liable to crack badly before the fruits are ripe. This may be anticipated either by the maintenance of a drier atmosphere, or by cutting the fruit before they are quite ripe, these being placed on a warm shelf to ripen. If screened from fierce sunshine, and which is apt to bake the fruits, neither colour nor quality will be much affected by this early cutting. This season our plants are again heavily syringed as often as the Peach trees in the same house, and this appears to be a sure preventive of cracking. Syringing also greatly checks the spread of the very troublesome tiny white fly known as *Aleyrodes*, and red spider is similarly checked.

The Potato fungus, *Peronospora infestans*, sometimes attacks Tomato plants under glass, and should this be discerned a little fire heat ought to be given and a drier atmosphere maintained. It is also necessary to at once destroy the affected plants before the disease spreads through the house. There appears to be no remedy for the disease which attacks the points of the fruit, this also being a fungus growth, and as far as my experience goes all that can be done is to at once destroy the affected fruit. The disease already alluded to—viz., *Cladsporium fulvum*, is at present most prevalent in the Channel Islands, and unless a remedy is soon found it will probably lead to a discontinuance, for a time at any rate, of Tomato culture in districts where the bulk of the fruit imported to this country is now grown.

For exhibition purposes the preference is usually given to the rich red round-fruited varieties, these "taking" better than the ribbed or corrugated varieties or any of a pink shade of colour. Carter's Perfection is one of the best that can be grown, this attaining a good size, is very handsome, and of first-rate quality. Livingstone's Perfection much resembles it, as also does the heavy cropping Hackwood Park Prolific. Selected fruit from Trophy or Stamfordian are very fine in every respect. Mikado is very distinct and succeeds well in the open air, but the pale colour is objectionable. Turner's Hybrid, selected from it, is very superior, the colour of this being a very rich dark red. Either Acme or Dedham Favourite are suitable for collections of Tomatoes, as also are Large Red, Golden Queen, and Large Yellow.—EXHIBITOR.

PERENNIAL CORNFLOWERS.

AMONG hardy perennials destined to become popular plants these Cornflowers are notable, as they possess a vigorous constitution combined with free and continued flowering, and their flowers are highly valuable in a cut state. Few plants are of easier cultivation, and all succeed in fairly well enriched loamy soils; at the same time they well repay for liberal treatment, and plants should not be allowed to stand in one position for any longer period than two years. They can be divided and replanted after flowering, but March and April are in reality the best months for planting, except that there is the danger of sacrificing many flowers that may be expected in June. They can be transplanted after the June flowering by giving a little protection from hot sun and a thorough soaking of water occasionally, while in an exceptionally wet summer like the present it hardly feels the moving.

Not the least important feature in connection with these Cornflowers is their picturesque form, thus rendering them particularly distinct and effective when arranged with other flowers in vases. All the varieties are increased freely by division and also by root cuttings, the latter being best inserted when the plants are dormant. They also seed freely provided the flowers are allowed to stand; but it may be well to observe that the seedlings are often much varied, some of them deteriorating in a surprising degree; still good varieties do appear among the rest. At the present time in most of the varieties there is a decided lack of substance in the flowers, which may be regarded as their weak point. This is more noticeable in the type and flesh-coloured forms, while an increased number of florets would be a great improvement in the white. Much the best and fullest flowers come from the variety *rubra*, and these are of a pleasing rosy red, very attractive, and certainly a most valuable perennial. There is a tendency of the centre florets to fold inwards, cupped as it were, which produces good effect. The florets of all the other forms radiate horizontally. The varieties best known are the blue, white, flesh, and red. There is also a so-called sulphur variety; the name is however misleading, the colour being a dirty cream tint, very probably a seedling, as it is the counterpart of some I flowered a short time since. All the foregoing are supposed to be forms of the Mountain Cornflower, *Centaurea montana*, though none of them has the deep green glossy

leaves which mark the type. This may also be distinguished by its narrower and more lance-shaped leaves. In all the other varieties mentioned the leaves are much more woolly and inclined to ovate acuminate, while all appear to vary somewhat in leafage, so much indeed that I have wondered whether they are really the offspring of one species.—J. H. E.

ROYAL HORTICULTURAL SOCIETY.

JULY 10TH.

SCIENTIFIC COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair; Messrs. Smee, Boulger, W. G. Smith, J. O'Brien, D. Morris, and Dr. Masters.

Insects Attacking Shoots of Ash.—Mr. Boulger mentioned, on the authority of Mr. Stainton, that the insect was probably one of the *Tineidæ*, *Prays Curtisellus*.

Plague of Caterpillars, &c.—A further discussion took place on this subject, in the course of which Mr. O'Brien alluded to the abundance of carwigs (*Forficula*) this season. Mr. Wilson drew attention to the local distribution of the caterpillars. In one garden in his neighbourhood none of the pests were found, while in others there was scarcely a leaf on the tree. At Wisley, Mr. Wilson had found that exposure to east wind was associated with the presence of insects; thus the trees in one line of Plums, fully exposed, were stripped of their foliage, while in another line of the same variety close by, on the same description of soil, but where the trees were sheltered by a Furze fence not a leaf was injured.

Fungi on Cucumbers and on Poppies.—Mr. W. G. Smith exhibited leaves of Cucumbers affected with *Didymium dædaleum*, and also Poppies attacked by the *Peronospora arborescens*, in consequence of which the flower stalks were lengthened and spirally twisted.

Lalia Eyermannii.—Mr. O'Brien made some remarks relating to this plant, which is remarkable for the presence of well-developed leafy bracts (not membranous sheaths), at the base of the flower stems. By some the plant is considered to be a hybrid between *L. autumnalis* and *L. majalis*. As there was some doubt expressed as to whether the existence of leafy bracts might not be accidental, it was suggested that the plant be exhibited again another year.

Odontoglossum Eugenes.—A plant of this was shown, and was considered to be a form of *O. excellens*, and possibly of hybrid origin, *O. Pescatorei* being one of the parents.

Anthurium Rothschildianum.—From Messrs. James Veitch & Sons came a plant with two spathe from the same stock. One of the two was much more densely spotted than the other.

Epidendrum vitellinum.—From Messrs. Sander came flowers of this species, in which, although the flowers were not fertilised, the ovary beneath the flower was enlarged, its colour glaucous-green, with six prominent orange-coloured ribs. Subsequent examination showed that the pollen-masses had not been removed, and that, although the ovary was swollen, the ovules in the interior were imperfectly developed.

Diaceous Strawberries.—Mr. Morris forwarded a letter from Mr. Colebrook on the subject of the well-known tendency towards the separation of the sexes in Strawberries, especially in the United States.

Tomato Disease.—A letter was read which had been written to Mr. W. Iggulden by a Guernsey grower detailing the course of this too well known, or rather these too well-known diseases. The writer's plants were in a span-roofed house, 60 by 25 feet, and were affected last year, when sulphur was applied without effect, the leaves were speedily affected but not the fruits. After the removal of the crop the grower took the precaution to have the walls washed with lime, to renew the soil, and adopted every known means to secure healthy growth, but this year the disease is worse than before. One grower was mentioned as having seven houses, each 350 by 45 feet, decimated with the disease and not a pound's worth of saleable fruit in before. Mr. W. G. Smith referred to the full description and illustration of the several fungi known to attack the Tomato, given in the *Gardeners' Chronicle* in 1881, November 12th, and in 1887, August 6th, October 1st and 29th, by Mr. C. Plowright and himself. Dr. Masters suggested the trial of sulphate of copper in fine powder, mixed with precipitated lime, and dusted over the foliage, as used in the French vineyards.

Monstrous Cypripediums.—Various specimens from Mr. Tautz and Mr. Pollett were shown, and referred to Dr. Masters for examination and report.

VACANT GROUND IN KITCHEN GARDENS.—Early crops are now being removed from their growing quarters in all gardens. These include Potatoes, Peas, Spinach, and Turnips, and this affords an excellent opportunity to plant winter crops. It is not yet too late to plant Savoy, Broccoli, Brussels Sprouts, and Greens generally. As our south borders are cleared of Potatoes the ground is at once filled with Veitch's Autumn Giant Cauliflower and Veitch's Self-protecting Broccoli, both of which merit a good position. We do not wait until a long border is cleared, but as every half-dozen rows or so are lifted the plants are placed in. Turnips and Spinach are also sown on some of the vacant ground, and it is only by attending strictly to this rule of planting that we can keep up a large supply of winter and spring vegetables. No one ought to feel satisfied with one crop a year out of the garden. Two at least should be secured, and three if possible. In planting very late Broccoli we always study to put them at the end of a quarter, as they will not

be ready until next May, and it is well to have them out of the way of other crops.—K. G.

REVIEW OF BOOK.

Choice British Ferns, their Variety and Culture. By CHARLES T. DRUERY, F.L.S. London: L. Upcott Gill, 170, Strand.

MR. DRUERY was well fitted for the production of a popular work on British Ferns, for he is widely known as an enthusiastic and skilled pteridologist; this book therefore possesses special interest to cultivators of hardy Ferns. After a chatty introduction the collection and cultivation of British Ferns is considered in seven chapters; then comes a division devoted to "the Fern Families of Britain," which are described in eighteen chapters, enumerating the most distinct varieties, the characters of the types being illustrated in numerous small figures. In the appendix the papers on Apocspory, contributed by Mr. Druery and others to the Linnean Society's Journal, are republished, and the book abounds in scientific and practical observations of a very entertaining character.

Referring to the variation in British Ferns the author thus sums up their chief peculiarities:—

"*Cristation*.—This consists in a multiplication of some or all of the extremities of the fronds and their subdivisions, forming a more or less heavy tassel. This ranges from a simple forking of the tip of the frond only to an infinite division of all the parts, from the main stem upwards, and has been carried to such an extent in several species that, instead of a flat feather-like frond, we have apparently a ball of very fine moss all but resting on the soil. This cresting, which more commonly takes the tassel form aforesaid, is in its turn varied infinitely in its character, not merely by the multiplication of the divisions which form it, but also by the mode of such division. Thus it may divide symmetrically in the same plane, forming a wide or a narrow fan-shaped crest; or these divisions may be again subdivided symmetrically, at greater or less distances, forming a flat lattice-work. Let, then, each division be more or less twisted, and every degree of curvature will give a different effect; or the simple fan may be elongated, and tips fanned out again. Here we have, manifestly, already a great scope, yet this is doubled by the capacity of the divisions to radiate, like the blossom of a Geranium (corymbiferous), with all the like variation repeated. The crests may also be formed by undivided expansion of the tips, like a duck's foot, instead of a crow's, to give a familiar example. Then, again, all these combinations are connected with the other varying characteristics of the frond itself, which may have overlapping or distant sub-divisions (pinnae, pinnules, or pinulets, according as they form first, second, or third divisions), all of which affect the result so much that the eye can easily distinguish the differences which characterise many variations of the same normal form. This cresting, in one or other of its forms, is the characteristic of the major number of known varieties.

"*Plumation*.—This is by some considered, and with reason, the most beautiful type of variation. It consists either in a much more delicate division and growth of the ultimate sections of the frond or in a greater foliaceous development, the result being as great a difference between the common and plumose forms as that between a goose feather and an ostrich feather amongst the divided Ferns, such as the Lady Fern, the Male Fern, &c., and between a plain strap and an elaborate fringed frill in the case of the Harts-tongue type. In this class of variation the normal outline of the frond is maintained, or merely widened, except, of course, where it is combined with cristation, which is frequently the case.

"The plumose character is usually accompanied by partial or entire absence of spores, the reproductive vigour of the plant suffering, apparently, at the expense of its leafy development, precisely as in the case of double flowers, to which it probably furnishes a parallel. There seems, however, good ground for the belief that though spores are not formed, or very sparingly, the reproductive powers of the plant are enhanced in other ways, such as by the production of buds, latent or evident, on various parts of the fronds. From experiments we find that the barren Harts-tongue—i.e., the crispum or frilled section, can be propagated much more freely from sections of the bases of the frond stalks than is the case with the fertile varieties. This would harmonise with Darwin's hypothesis of pangenesis, and suggests the advisability of a closer investigation of the so-called barren forms generally.

"*Dwarfing and Congestion* are self-descriptive terms. Some of the dwarfed forms are extremely pretty, and specially adapted for small collections where space is very limited. Most of the species have afforded examples of this, coupled with other types of variation.

"Congestion characterises many forms, and consists in a more or less crowded and overlapping state of all the divisions, and since it usually, though not always, involves shortening of the stalks as well, generally accompanies dwarfing, and hence is classed with it.

"*Depauperation* is a common form of variation, and is rarely regular enough in its effect to be beautiful. It is curious in its way, thoroughly healthy and vigorous plants constantly producing fronds on which the tips or some of the pinnae are either altogether missing, irregular in length, or very ragged and imperfect, exactly as if devoured by insects. These oddities are, nevertheless, truly transmitted, in most cases, by the spores.

"*Variegation*.—This is very rare, and we believe there have been found no regular variegated forms, such as some of the exotic species have

produced—e.g., *Pteris cretica albo-lineata* and others. Some forms of the divided Ferns have been found irregularly splashed with white; and yellow Harts-tongues are not rare in collections.

"The above form the main types of variation, and two or more of them may be, and frequently are, conjoined in one and the same plant, which, of course, immensely increases the scope. Besides these there are endless forms which can only be classed as oddities, such as the cornute and truncate forms, where the frond is cut short, as it were, the midrib projecting suddenly from the face or back of the frond, like a thorn; or the frond ends abruptly in a pocket, or horn, or frill, or all these combined; serpentine forms, where all the parts and the whole Fern itself are lengthened and twisted about like a serpent, striving, as it were, to become a climbing plant, like some of its foreign relations; marginate forms, where lines or ridges run along the upper or lower surface, parallel with the edges or midrib; revolute forms, where the frond is rolled up longitudinally like a tube, the divisions taking a half-circle curve backwards; caudate forms, where the divisions end in a tail; and so on *ad infinitum*.

"*Proliferation* characterises many varieties; in this little plants appear on the stalks, edges, faces, or even the backs of the fronds. Many of the soft prickly Shield Ferns (*Polystichum angulare*) are thus affected, and look remarkably pretty when the young plants develop, as they do in profusion all along the centre of the frond, and sometimes of the pinnae.

"The same form of variation, carried to excess, often so far obliterates the differences between the species that it requires an experienced eye to recognise them. Nothing, for instance, can be more dissimilar than the Lady Fern and the Harts-tongue, yet there are forms of both, dwarf and extremely crested, that are as like as two peas. The robust or giant forms of some of the smaller-growing species, and the dwarf forms of the larger, also contribute frequently to a likeness in the varieties which does not exist at all in the normal types. Fronds, for instance, of the common Polypody, fully 2 feet high, and beautifully cut, lose all likeness to the common, and resemble the Shield Fern varieties; while the dwarf form of Male Fern (*Lastrea pseudo-mas ramosissima*), about 3 inches high, would be relegated by most people to any species but the right one.

"The affinity, too, between the plain strap-shaped Ferns and the much-divided ones is also curiously shown in several varieties of the Harts-tongue (proectum series), in which there is a manifest and regular tendency all along the frond to form pointed side divisions. The converse case is seen in some of the strap-shaped varieties of the Hard Fern, in which the double comb is also obliterated."

The subject is pleasantly treated, and in some cases a quaint humour renders the book very agreeable reading.

THE COLOGNE EXHIBITION.

IN reference to the International Horticultural Exhibition to be held at Cologne in commemoration of the twenty-fifth anniversary of the Flora Garden Company from the 4th of August to the 9th September, 1888, we have received the following communication from the British Consulate at Düsseldorf.

This important Exhibition, which is honoured by the patronage of the Dowager Empress-Queen Augusta, under the presidency of Prince Wilhelm of Wied as Honorary Chairman of a distinguished and able General Committee, will be opened on the 4th August next. Baron Ed. von Oppenheim, Imperial Austrian-Hungarian Consul at Cologne, Chairman of the General and Executive Committee, informs me that they are desirous that British products and manufactures, machinery and appliances connected, directly or indirectly, with the main object of the Exhibition, shall be largely and well represented.

I have the honour of drawing special attention to this Exhibition, which promises to be the most successful one of its class ever held in the Rhenish Province—the pearl of the German Empire. A better opportunity for promoting the export trade to the Continent in the branches of industry concerned could hardly be afforded—within so easy reach of British ports—elsewhere than at Cologne, one of the most central points of traffic in the most industrial and thickly populated provinces of Germany.

In the Rhenish Westphalian provinces great progress has been made of late years in the cultivation of gardens and parks on the English system, a taste which is daily being more and more developed with consequent increased requirements. In some branches of horticulture Holland and Belgium rank very high, but in most classes of industry connected therewith the English products and manufactures are superior; however, in these days of world-wide competition, mere advertisement and issue of circulars no longer suffices. To ensure success the quality must be proved by exhibition wherever and whenever opportunity is afforded.

The programme in German, list of chief products and manufactures in English, including no less than 750 kinds of exhibits, is a very comprehensive and extended one, to which exhibitors are not strictly limited. All classes of products and manufactures in any way, even indirectly, connected with horticulture and model farming will with pleasure be received, and every facility will be given for cheap and expeditious transport, suitable mode of exhibition and representation, no charge being made for space. All applications for further information made to the Executive Committee, Gartenbau, Ausstellung, Cologne, will be promptly attended to.

It is desirable that such applications be made as soon as possible. The Committee has such a considerable amount of funds at disposal that prizes for exhibits not already specified in the printed programme can, I am informed by the Chairman, and doubtless will, be granted, the wish being to further develop, in every way possible, the science and art of horticulture in the widest sense of the word.

The exhibits admitted to competition for gold, silver, bronze medals and money prizes include hothouse, conservatory, garden, and field plants, as well as seeds of all classes, also the products thereof, and the manufactures therefrom, including wine, beer, porter, vegetable oils, sugar, resin, indiarubber, hemp, flax, jute, bast, and cotton, coffee, tea, and tobacco, fruit in natural and preserved state, and vegetables of all classes, garden architecture, plans of and designs for gardens and parks, models and exhibits of hothouses, conservatories, with apparatus for heating and shading the same; summer houses, permanent and portable; tents, garden furniture, verandahs, aquariums, aviaries, poultry, swan, and duck houses, all kinds of garden, park, and field iron and wooden fences, tiles, sculpture, vases, urns, and pedestals, material for construction of watertight ponds and cisterns, especially without the use of cement: flower baskets, appliances for the decorative illumination of gardens, parks, conservatories, &c., garden and park engines, machinery, implements, and mechanical appliances of all sorts, such as hydrants, hoses, pipes, fittings, irrigating appliances, water carts, syringes, &c., pumps, motors, and all apparatus connected therewith; mowing machines to be worked by hand, pony, or donkey power; horse, pony, and hand carts of all sorts; surveying, levelling, and drawing instruments, &c.

Flower pots and tubs for ornamental plants, labels, bouquet easels and holders, apparatus and appliances for drying fruit and vegetables, bouquets, wreaths, fans, &c., flower stands and table decorations, ornaments for dinner tables, drawing rooms, &c., sample of the best materials, wire, &c., for tying bouquets, hair dressing, and decoration.

Collections of herbs, wood and seeds, butterflies and insects, petrified plants and fossils; bee farming, working bees, hives, and appliances connected therewith, samples of honey and wax, literature on bees and bee-farming, literature on horticulture; in fact, as will be seen by the programme, all classes of exhibits are included which are directly or indirectly connected with the most improved cultivation of gardens, parks, and model farms, a branch of industry taken as a whole which is further advanced in the British Isles than any country in the world. No charge will be made for space required for exhibition.

The foregoing is a list of some of the chief products and manufactures enumerated in the programme received from Baron Edward von Oppenheim, Chairman of the Executive Committee.—J. R. MULVANY, *H.B.M. Consul for Westphalia and the Rhenish Provinces, British Consulate, Düsseldorf-on-the-Rhine.*

P.S.—Since writing the foregoing, I see by a supplementary programme that 21,700 marks (£1088) have been subscribed for money prizes.

GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY.

A GRAND summer and Rose Show was held on July 11th and 12th under the auspices of the International Exhibition Committee, the funds being provided by the Executive of the "International." Two large marquees were erected in a sheltered spot in the beautiful grounds of Kelvin Grove Park, the half of which is this year enclosed as part of the Exhibition grounds, and is a most delightful retreat to sightseers when fatigue compels them to come outside. The arrangements were as usual carried out under the skilful superintendence of Mr. Franc Gibb Dougall, and proved very satisfactory, plants and flowers being admirably disposed in both tents, giving a most pleasing sense of varied beauty.

The large collection of plants shown by Mr. R. Bullen, Botanic Gardens, in the Rose tent, added greatly to the effect. The eye turned with relief from the mass of colour on the Rose table to the varied shades of green in the Botanic collection, and the popular names attached to the plants proved a source of great interest to the visitors who thronged the tents. Over a hundred varieties of official medicinal plants were shown, among them being some very large specimens. Special notice was taken of two large plants of Sugarcane, a magnificent specimen of the Tea plant, and many others too numerous to mention. Messrs. J. & R. Thyne, Great Western Nurseries, Kelvinside, had the only collection of plants in the nurserymen's class, the space filled being about 200 square feet. Although the stimulus of opposition was wanting the arrangement was done with the elegance and taste for which the firm is famous. Messrs. Jas. Bryson & Son, Helensburgh, exhibited a collection of Roses in pots, and a plant of Blackberry (Wilson, junior), in fruit. A magnificent plant of *Stanhopea tigrina* suspended from the roof in the tent attracted much attention. About fifteen fully expanded blooms formed a beautiful wreath, completely hiding the bottom of the basket in which it was grown; the colour was very dark and the spots few. An enormous model flower garden was shown by Mr. R. Millar, Netherhill Gardens, Paisley, containing a very pretty range of model plant houses. Mr. M. Campbell, nurseryman, High Blantyre, had a large collection of Pyrethrums, Pansies, Carnations, and Begonias, for which he was highly commended. A seedling Pansy named Lizzie Duncan received a first class certificate, an honour it also received at Edinburgh. Messrs. R. B. Laird & Sons, Edinburgh, showed a stand of Pyrethrums of excellent quality, all named sorts tastefully set up, many

of the blooms rivalling in form quilled Asters. This collection was very highly commended. Mr. A. Lister, Garfield Nursery, Rothesay, exhibited a large collection of fancy Pansies; many of them were seedlings of good quality, a stand of twenty-four blooms being highly commended. Mr. Geo. Bainbridge, florist, Eglinton Street, had some choice bouquets and chaste floral wreaths, for which he was very highly commended.

Cut Flowers.—Roses.—In the class open to all for sixty blooms Roses, distinct varieties, Mr. Hugh Dickson, Belmont Nursery, Belfast, had first prize with very beautiful blooms, not so large as we have seen in more favourable seasons, but the quality was all that could be desired. Some of the more striking varieties in the stand were A. K. Williams, Benoit Comte, Earl Dufferin, Lord Bacon, Merville de Lyon, Mabel Morrison, and a splendid bloom of Etienne Levet, which gained the first prize for the best bloom in the Exhibition. Messrs. Harkness, Bedale, Yorkshire, had second, and Messrs. A. Dickson & Sons, Newtonards, third. For forty-eight blooms Messrs. A. Dickson & Sons had the first prize, Mr. Hugh Dickson second, and Messrs. Harkness third. In the class for twenty-four blooms of Roses a local grower came well to the front, Mr. David Robertson, Mossend Nursery, Helensburgh, taking the first prize; Mr. Wm. Montgomerie, Cardross, second; and Mr. Thos. Smith, Stranraer, third. In the class for Tea or Noisette Roses Mr. Robertson was again first with very fine blooms of Rubens, Niphotos, Madame de Watteville, Madame Faleot, and Grace Darling. Mr. Robertson was also first for twelve trusses of Moss Roses. For twelve blooms *Maréchal Niel* Roses, Mr. Tinsely, Lennox Castle Gardens, had an easy victory over Mr. Wm. Parlange, Row. Messrs. Harkness & Sons had the best six blooms of A. K. Williams.

Messrs. Perkins & Sons, Coventry, had first prize for the best basket of Roses and Ferns, best basket of assorted flowers, and the best bouquets of bridal and assorted flowers. The exhibits of Messrs. Perkins were a feature of the Show. We are accustomed to fine bouquets in Glasgow, but those from Coventry could not have been excelled. The baskets were works of art, calling forth the admiration of the lady visitors. In the class for thirty-six blooms, Roses, the local champion, Mr. Wm. Parlange, Helensburgh, easily held his own, gaining the first prize and the Veitch Memorial medal.

In the other tent fruit and cut flowers were arranged round the edge, plants filling a large table in the centre. A decorated dessert table, 10 feet by 5 feet, was put up by Mr. W. B. McNeil, 6, Blantyre Street, and was much admired; the fruit and flower dishes and gift service being kindly lent for the occasion by Messrs. Ostler of London and Birmingham from their magnificent collection in the International Exhibition.

Plants.—The prize for six stove and greenhouse plants was awarded Mr. Thos. Hogg, gardener to Mr. J. Gordon Aitkenhead, Cathcart, the same exhibitor having also the prize for three stove and greenhouse plants. Mr. Geo. Meston, gardener, Mercia House, Pollokshields, had first prize for a table of plants arranged for effect, and the best Tree Fern. Mr. Mathieson, gardener to J. L. Henderson, Esq., Westbank, Partick, had first prizes in the classes for six foliage plants, three foliage plants, and one specimen Palm, *Kentia Belmoreana*. The Palms in this collection were exceptionally fine. The prizes for six exotie Ferns, six British Ferns, and six pans *Lycopodiums* were in each case gained by Mr. Caughie, gardener to ex-Provost Kennedy, Partick, and were all admirable examples of cultivation. Table plants made a splendid display, and have not been exceeded in quantity or quality in any previous exhibition in connection with this Society. Messrs. R. B. Laird & Sons, Edinburgh, won the prize in the open class, Mr. R. Grosart, Oswald Gardens, Edinburgh, carrying away the first in the gardeners' class. Mr. Grosart had also first for six trusses of *Oreohids*, *Cypripediums Veitchi* and *C. Stonei*, very fine, and three *Draenas* in 8-inch pots, *D. Lindenii* in very fine colour. For twelve trusses stove or greenhouse plants, *Oreohids* excluded, Messrs. R. B. Laird was first, with choice bunches of red and white *Lapagerias*, *Dipladenias*, *Stephanotis*, *Allamandas*, &c., very tastefully put up. In the *Oreohid* classes Mr. David Wilson, gardener to Hugh Steven, Esq., Westmount, Kelvin-side, had it all his own way, being first for three specimens and one single specimen, his specimens of *Odontoglossums* being large and very superior forms. Mr. Wm. Cowan, Clelland Gardens, Campbelltown, had the best *Ericas*; Mr. J. Robertson, Springbank Gardens, Stirling, had the best *Crotons*. Mr. Cullen, Balornack Gardens, had the only three *Fuchsias* shown; they were, however, magnificent specimens.

Amongst numerous fine stands of herbaceous cut flowers, Mr. Wm. Storrie, Gargabet, Lenzie, had the first prize for a really grand collection. Mr. John Sutherland, Victoria Nursery, Lenzie, had the best show Pansies. Mr. M. Campbell, Blantyre, the best faneles, while in the *Viola* class, Mr. Baxter of Daldowie Gardens, Broomhouse, had as usual the premier position in both the open and confined classes. His most telling varieties were Goldfinch, Rosy Morn, Lady Gertrude, Mr. Burns, Morning Star, York and Lancaster, Bullion, Delicata, Queen of Seats, Dawn of Day, and Columbine; the blooms were arranged in fan shape in Mr. Baxter's best style.

Fruit.—This was very good for this time of year. For collection of fruit, six dishes, Mr. J. Macindoe, Hutton Hall, Guisborough, was awarded the first prize. Mr. Macindoe was also first with six Nectarines, and the same honour for Cherries; he also secured the first place for a collection of vegetables of high quality. Mr. McHattie, Newbattle Abbey, Dalkeith, had all the honours for Grapes, securing first for four bunches Grapes, at least two varieties, two bunches white Grapes and two bunches black, all excellent examples, attracting a large

amount of attention. Mr. McHattie had also first for six Peaches with Rivers' Early York. He also secured the prize for a dish of Figs. A pretty case of Mushrooms from the Scottish Mushroom Company, Edinburgh, was very highly commended, and proved a source of much interest to the visitors.

Mr. Thos. Johnstone, Renfrew, had a large stand of his Orchid basket and plant tubs, very well finished; also specimens of his teak stakes for Orchids, and pitch pine stakes for Chrysanthemums, which are a great improvement on the German and quite as cheap, for which he was very highly commended.—KELVIN GROVE.

EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY.

THE twenty-fourth annual Exhibition was held in the grounds of the Royal Indian Asylum, kindly placed at the disposal of the Committee by Dr. Christie. The weather was unpropitious, the day being an ever-to-be-remembered one, Wednesday, July 11th, for the bitterly cold weather, with snow in many parts of the kingdom; still there was a great attendance of visitors, and the Exhibition from all points of view was an excellent one. We are unable to give a detailed report of the Show.

Roses were there in considerable numbers. For twelve Teas or Noisettes, Mr. G. Prince, Oxford, was first with blooms of large size and first-class quality; Messrs. Paul & Son second, and Mr. C. Turner third. For twenty-four trebles, first, Messrs. Paul & Son; second, Mr. C. Turner; third, Mr. Prince; fourth, Mr. Wm. Rumsey. Other classes also were well filled. Messrs. James Veitch & Sons and Messrs. C. Lee & Son each sent six boxes of fine blooms not for competition. F. G. Tautz, Esq., contributed a good group of Orchids, and Mr. Roberts, The Gardens, Gunnersbury, set up a very beautiful group of plants, consisting of Palms, Dracenas, Ixoras, Gloxinias, very fine Souvenir de la Malmaison Carnations, a very first-rate strain of crimson and yellow *Celosia pyramidalis plumosa*, a striking feature of the group, the whole fringed with *Panicleum variegatum*. Mr. Roberts also staged, not for competition, a group of fine Gloxinias in pots, embedded in Maidenhair Ferns. Messrs. Fromow & Son set up a group of plants. Mr. C. Turner, a fine group of medium-sized Pelargoniums, two of which, both fancies—viz., *Ambassadors* and *Mrs. Hawtrey*, received certificates. Messrs. C. Lee and Son contributed a telling group of ornamental trees and shrubs in pots, most interesting, and we wish they were more cultivated than they are. This admirably arranged group contained so many rare and beautiful plants that a lengthened report would hardly do justice to them, but amongst the dark rich coloured foliage plants *Prunus pissardi* and *Acer Schwedleri* stood out prominently. *Impatiens Sultani* from seed were examples of excellent cultivation, sent by Mr. Roberts; and Mr. A. Wright, The Gardens, Devonhurst, Chiswick, deserves praise for his four first prize well grown Fuchsias, as well as for his first prize pyramidal *Sclaginellas*.

Some capital flowering stove and greenhouse plants were shown, and good groups of plants. There were six competitors for the larger groups, Mr. Hudson, Gunnersbury House Gardens, taking the first prize. There were seven competitors for the smaller groups. Mr. B. S. Williams of Holloway sent, not for competition, a charming and interesting group of novelties.

The table decoration tent was one of the features of the Exhibition, the classes well filled, and refined taste was so prevalent. Rarely have we seen so charming a display. The cottagers' tent was crowded with exhibits, and surprise was freely expressed that so much quality was to be found throughout. Eight hundred dishes and plates were used for single dishes and small collections. There were 405 entries in the cottagers' class, which included twenty-two entries for three dishes of vegetables, twenty-one entries for two dishes of Potatoes, twenty-two entries for three Lettuces, the first prize a silver watch, fifteen entries for six varieties of vegetables, seventeen entries for four varieties of vegetables, nineteen entries for autumn-sown Onions, twenty-three entries for two varieties of Potatoes, nineteen entries for dish of Peas, fifty pods, so it will be seen that the Judges had their work cut out. The cottagers deserve the highest praise, and the gentry and tradesmen of Ealing are most generous in providing extra prizes in these classes. The display of bouquets of wild flowers and garden flowers by school children was very astonishing, nearly 450 being exhibited, and we are inclined to think that Messrs. Sanderson and Ballantine, the Judges, never had a harder task.

SURPLUS VEGETABLES.—It may be thought that to have more Beans, Peas, and other vegetables than can be consumed is good. It is certainly better than a deficiency; but having a surplus is not without evils. We sometimes hear of a glut at one time and a scarcity at another, and there is nothing will bring a scarcity quicker than having a surplus, because when the produce gets too old it immediately causes the younger pods and heads to cease swelling, and they never come on for a satisfactory succession, whereas if they were gathered closely as they become ready the later produce would swell to the last. If we wanted a row of Peas to cease bearing we would not gather any pods from it, but to prolong it for some weeks we would gather every one from the first. It is more economy to gather surplus vegetables and give them away than to allow them to remain to spoil the plants and a succession.—J.

FRUIT FORCING.

MELONS.—If fruit of these be required very late a last sowing should now be made, but unless there be a light and well heated structure available the prospect of a crop will be indifferent. It is desirable to choose for this sowing varieties that will keep some time after being ripe, as Scarlet Premier in scarlet-flesh and Longleaf Perfection of the white-flesh sections. Both are good setters and swell well late, or at any time for that matter, in the season.

There must not be any further delay in placing out the plants for affording ripe fruits in October, it being equally necessary that they have a light well heated structure. If the weather be bright and the temperature at night does not fall below 65° fire heat may be dispensed with, only it is necessary that the bottom heat, if derived from fermenting materials, be 90° at the commencement, as they will gradually lose heat, and if from hot-water pipes 80° to 85°, the temperature of the house by day 70° to 75°, advancing with sun heat to 85° or 90°.

In pits or frames the last plants are setting their fruit, and a good watering should be given if necessary before the flowers open. If watering is necessary during the time the fruits are setting it should be done carefully, as a dry atmosphere with rather free ventilation is essential to a good set. As soon as the fruits of the different crops are set and swelling earth the plants freely. Keep the growths well in hand after the fruit commences swelling, so as to admit light and air to the principal leaves, also stop all lateral growths to one joint. Syringe freely and afford copious supplies of water, except during the setting and ripening periods. If canker appear at the collar promptly apply quicklime, rubbing it well into the affected parts, and if there be any indications of the fruit cracking cut the stem halfway through a few joints below the fruit, reducing the supply of water at the roots and maintaining a dry well ventilated atmosphere.

PINES.—Houses as they become vacant should be thoroughly cleansed before being again occupied with plants. The first thing to be seen to is the bed. If bottom heat be afforded by hot-water pipes, the material forming the bed, whether of tan or leaves, should be removed at least once a year, or insects, particularly woodlice, increase rapidly. The old material also harbours other predatory vermin. Brush all wood with hot lime, the wood and iron work being thoroughly cleansed with soap and brush, keeping the soapy water as much as possible from the glass, which ought to be cleansed with water only. If needed the wood and ironwork should be painted. Beds that are chambered—i.e., the hot-water pipes covered with slates or other material, are much in advance of those passing through beds of rubble. Those composed of the latter should be turned, and dirt or small parts removed, to allow the heat given off by the pipes to penetrate through the whole and diffuse a uniform temperature to the bed. New material will be required for the bed. Fresh tan should be provided, of which 3 feet depth is ample where pipes are placed beneath to maintain the requisite temperature when that of the fermenting material is declining, and about 1 foot or 18 inches more where there are no pipes. If it be wet turn it occasionally on fine sunny days.

Suckers that were started in June will soon fill their pots with roots, and must be shifted into larger pots before the roots become closely matted together. Queens require 9 and 10-inch pots, and those of stronger growth 11-inch pots. Supply water immediately after potting, and plunge the pots in a bed having a temperature of 90° to 95°. There is no greater mistake in growing Pines than crowding young plants, which causes them to become drawn and weakly. Attend to the bottom heat of beds that have recently been disturbed by the removal of plants, not allowing the heat to exceed 95° at the base of the pots without immediately raising them, as too much bottom heat will disastrously affect plants with fruit or those having the pots filled with roots. Examine the plants for watering about twice a week, and maintain a moist, genial, well ventilated atmosphere. The climatic influences are now so favourable that Pine plants grow luxuriantly, therefore discontinue any shading such as may have been employed for an hour or two at midday when the sun was powerful through the months of May, June, and early July, the plants after this, unless the weather be very scorching, having the benefit of every ray of light, admitting air plentifully when the temperature ranges from 85° to 95°, affording to fruiting plants a night temperature of 70° to 75°, and succussion 65° to 70° at night. Reserve if possible suckers on the stools for starting at the commencement of September.

PEACHES AND NECTARINES.—*Early-forced Trees.*—After the fruit is gathered from the trees started in December and early January, whether they are of the very early or the second early varieties, the strength will be centred on the swelling of the buds and maturation of the wood. To effect this perfectly it is necessary that the foliage be kept healthy, syringing forcibly to expel red spider and other insects, if necessary applying an insecticide. The wood which has borne fruit, not being extension, should be cut away; indeed, remove all wood not required for fruiting next season or for furnishing the trees. There

must not be any lack of moisture at the roots, and weakly trees may be assisted with weak liquid manure. Ventilate to the fullest possible extent, and when the buds are sufficiently plump and the wood mature remove the roof lights. The chief thing to guard against in early-forced trees is premature ripening of the foliage. It is well to allow a moderate extension of the laterals, especially when the buds are prominent, so as to attract the sap from the buds and so keep them dormant, as any undue excitement will cause them to expand. Any trees not in a satisfactory condition should be marked for renovation of the border, whether it be lifting the roots of trees that do not set and stone the fruit satisfactorily, or those that from weakness need vigour by an addition of fresh soil, so as to cause an increase of roots in order to secure a better supply of aliment. This is best effected after the buds are plumped and the wood is mature, yet whilst the leaves are upon the trees, so as to facilitate the root-action, which promptly follows judicious and careful lifting, the trees not receiving any check if proper precautions are taken in shading from bright sun and damping as well as sprinkling the foliage until the trees have formed fresh roots.

PLANT HOUSES.

Gardenias.—Keep those intended for early autumn and winter flowering cooler, and the plants can be exposed to full sunshine and ventilation, so that their growth may be thoroughly matured. This must be done gradually, or instead of attaining the object in view failure will follow. For early flowers it is necessary to ripen the wood as early as possible, and then with an increase in the temperature the plants will soon form and swell their flower buds. Young plants rooted in August last will be strong and fully 15 inches in diameter. Allow the shoots to extend, admitting air daily to insure sturdy growth, and fully expose them to the sun. Soot water and other diluted stimulants may now be given once a week. A little artificial manure applied to the surface of the soil will be found beneficial. Plants rooted early in the year may have their shoots pinched once more; if not in 5 and 6-inch pots transfer them to those sizes at once. Insert cuttings of young shoots for next year's stock of plants.

Leoras.—Young plants that have flowered may be pruned and started again into growth in brisk heat. They should be grown fully exposed to the sun, with the general stock raised from cuttings at different times. When the plants are in active growth admit a little air daily, and if they are arranged close to the glass they will make firm short-jointed wood that is certain to flower. Plants grown in a close moist shaded atmosphere seldom flower satisfactorily. Large plants that have flowered may be partially pruned and started again into growth. Any shoots that have not flowered may be inserted in 2-inch pots, and will root readily and quickly in the propagating frame. If grown on afterwards many of these will flower this season, but those that do not will be useful for early flowering another year in 4 and 5-inch pots. Watch for thrips, which quickly destroy the foliage of these plants. A thorough syringing with a weak solution of tobacco water is the best means of dealing with them. Do not allow these plants to suffer by an insufficient supply of water at their roots; at the same time be careful not to overwater them, for they will quickly present an unhealthy appearance if the soil becomes sour.

Crotons.—These should be rooted in quantity where highly coloured well furnished plants are in demand for various forms of decoration during the autumn and winter months. Large heads can be rooted without losing a single leaf if they are taken off where the wood is soft. Small cuttings never make such handsome plants as those rooted with well coloured, fully developed leaves at the base. Good heads may be rooted in 4 or 5-inch pots as well as in those of a smaller size. Place in the centre of the pots a little sand for the base of the cuttings to rest upon, then water liberally and plunge the pots in the propagating frame. Shade from the sun and keep the frame close until roots have been formed. Directly they are rooted gradually harden and expose them to the light. The plants from which the heads have been taken may be allowed to break again, and the shoots produced when they have developed a few leaves will be suitable for rooting in 2 and 3-inch pots.

Dracena Goldiana.—Plants that have grown too tall for ordinary use may have their tops re-rooted. Be careful to take them off where the wood is soft, or it will be a long time before roots are formed. When the base of the stems is moderately soft they root quickly and readily without losing a leaf. The heads may be inserted in 4 or 5-inch pots, and after they have been watered plunge them in handlights where gentle bottom heat can be given. *Dracenas gracilis* and *Lindenii* may be treated in the same way. If the stems are kept they will yield cuttings from the axils of the leaves, which can be taken off and rooted any time when large enough.

FLOWER GARDEN.

Bulbous and Similar Plants.—Most of the spring-flowering bulbs are now matured, but it is unwise to lift them, either with the idea that they are more surely preserved out of the ground, or with the motive of dividing the clumps. Lifting, drying and keeping in sand or other somewhat dry material has a most weakening effect on the bulbs; whereas when lilies, Narcissi, Hyacinths, Snowdrops, Tulips, Anemones, Bulbocodiums, Crocuses, Fritillarias, Lachenalias, and Erythroniums are left in the ground they continue to improve. Just as they are coming through the ground is the best time to lift and carefully divide them should this be desirable, and being at once replanted without much injury to the young roots, they will flower the same season. Those moved when in a dormant state, this including wild Orchids, will flower

the first season after, but not often in the next. Those bulbs lifted from the flower beds and laid in to ripen, may either be left in the ground till wanted again in the autumn, or they can have the dead foliage cleared off, and be then packed in boxes of sand or fine soil. Ranunculuses require this treatment.

Hardy Bedding Plants.—These must now be attended to, as they cannot well be too strong or well rooted when transplanted to the beds next autumn. North borders are of the greatest service in preparing a number of plants that delight in a cool position, notably Daisies, Primulas, Polyanthus, Alyssum, and other useful plants. Plenty of leaf soil, old Mushroom-bed manure, decayed tan, or other somewhat similar material ought to be well stirred into the surface, plants moving well out of soil thus treated. All the plants named, as well as *Ajuga reptans rubra*, Arabises, Iberises, Hepaticas, Forget-me-nots, Saxifragas in variety, and Aubrietias, are readily divided, and should at once be deeply and firmly dibbled out in lines across the border, and watered in if need be. Violas and Pansies after they have pushed up fresh growth may also be freely divided and planted out in nursery beds. Gentians ought not to be divided unless extra strong, as they are somewhat impatient of rough treatment.

Seeds and Cuttings in Handlights.—Either handlights or frames are of good service for propagating purposes, especially in a showery season, or when seedlings cannot be preserved from slugs in the open. The north side of a wall or other somewhat cool yet not much darkened positions are the best places for setting these, bright sunshine being especially harmful to cuttings. If Wallflowers and Stocks have failed in the open, sow in these handlights or frames at once, and thinly, so as to admit of the seedlings being transplanted with a tiny ball of soil with the roots. It is rather late to sow Pansies, Sweet Williams, Campanulas, Carnations, Primulas, Polyanthus, and Myosotises, but the seed soon germinates under glass, and small plants are often serviceable. Cuttings or pieces pulled off double Wallflowers, Myosotises, Euponymuses, Alyssums, Iberises, dibbled in thickly in handlights or frames, watered in and kept shaded during that part of the day when the sunshine reaches a north border, rarely fail to strike root quickly. About 3 inches depth of fine sandy compost is preferable to ordinary garden soil, both as regards favouring an early strike, and also because the young plants are more easily and safely moved out of it.

Violas.—Divisions of both double and single varieties ought now to be growing strongly, red spider being less troublesome than usual. They thrive best when the old stem is quite buried, and any exposed ought to have the soil drawn up to them.

THE BEE-KEEPER.

GENERAL MANAGEMENT.

It is generally understood that I prefer keeping my bees in such a state that feeding is never resorted to unless the seasons are, like the present one, untoward and non-honey yielding. But even in the present summer, when hail and snow fell on the 10th of July, and only nine days on which I could say that the bees gathered honey in little excess of their daily wants, I have only given each stock half a pound of sugar on an average. Although the weather is now more genial, it has rained almost constantly for three days, with but little signs of improving. When bees require food, except in the case of swarms, it should be given them continuously and rapidly until they have had enough; and the handiest of all feeders, and the ones from which the bees take up the sugar quickest, are the under ones, such as I have described in previous articles, or the old-fashioned fountain.

For districts where the honey season does not begin until the end of June, such as our own, nuclei of not more than 2 lbs. of bees make the best stocks and give most satisfaction. Old queens I never depend on, even at one year. For early districts where the honey season begins in April or May stronger stocks should be kept, and in some late cold places it is advisable to follow the same course, but it would be wise of the bee-keeper to make experiments on this line. In all cases never allow the bees to have combs to make the current year of their working; either feed in September or make up from others until the hive is full. Should that not be possible full-sized sheets of foundation must be employed.

THE BEST HIVE.

For all purposes this is undoubtedly the Lanarkshire tiering, but hitherto the much-abused hive. With but slight alterations I

have used this hive for about forty years, and it has given me the greatest satisfaction; until with one, and the only one, exception, through an accident, I never lost a bee on my way to the Heather, and I have to take them long distances.

Bee-keeping has not been always managed by persons having the necessary experience, and bee-keepers in their novitiate state have, in many cases, been sadly misled. A standard hive was produced and held up as perfection, and no hive was admissible as a prizewinner at the big shows unless it was in accordance with the minds and ideas of the B.B.K.A. But, now, instead of one-sized standard frame, two are admissible, and tiering is the order of the day. This change the contributors to the "Old Journal" ought to be proud of, as it is now proven that it was the only one that allowed large and tiering hives to be recommended in its pages.

It has been recently stated that "George Raynor was the first to use carbolic acid as a bee-quieter," yet the *Journal of Horticulture* in earlier numbers tells a different tale, to the effect that carbolic acid, as well as creosote, was used as a bee-quieter long before we heard of that gentleman. A few stray leaves that I came across in my bee house lately gave me some information on the point of which I speak that will be borne in mind.

The hive that I use and recommend is the same as I have been using for forty years, and what I introduced to Stewarton some thirty years ago, and very much the same hive is now being adopted by bee-keepers generally. One difference is what is termed the break-joint; this was discarded by me when I had my second hive, as there should be nothing about the junction of boxes to make separation difficult. We cannot prevent the bees building their combs down to the top bars of the under boxes even when a bottom rail is used in the frame. In this hive I use no bottom rail, as there is the lost space the rail occupies, and very often half an inch above it, together with that below it. When there is no bottom rail there is very little lost space, and if the combs are sometimes fastened to the top bar of the under box all the better for the bees and bee-master; and when a severance is wanted a wire drawn through between is all that is necessary, a thing impossible where a break-joint is. The thoroughness of the ventilation floor makes it ahead of all other hives, and if the bees do occasionally fasten their combs to the top bar, of the two evils I have chosen the least.

THE SITE.

This, as well as the arrangement of the hives in September, should be well chosen, and in the most sheltered spot. Standing in twos or threes with a wide space between each clump prevents the bees mistaking their own hive (Carniolian bees are less liable to enter a wrong hive than other known varieties), and admits the sometimes necessary change during the swarming and working season.

After my hives are properly arranged and all well found in stores to prevent feeding during winter or spring, an inspection is made to see that all is wind and water-tight; they are never interfered with nor altered in appearance, a watch only being kept in case of accidents, and the snow removed from the front immediately after it falls. Owing to the bad season most of my hives, except the supered ones, are in the same state as I put them in September.

My first work in the summer is to make preparations for the next year, and for the purpose of preventing after swarms and to keep stock hives in full strength. This is done by encouraging a pure hive to swarm early or to make an artificial one. In about ten days after I divide it into nuclei, sometimes twelve are put into nucleus boxes with four frames and placed between but in the rear of the hives likely to swarm, which in a few days after are overhauled and all the royal cells destroyed, and the queen from the nucleus is joined, which is, as a rule, fertilised and laying. The advantage gained by this manipulation in a good season is doubly manifest. Stock hives get stronger with the young queen than it could do with the older, and swarming does not take place so

readily, and drone comb is not built in empty places as it would have been with an old queen regnant. As the season advances other young queens are raised, and these are kept sacred for the following year's work, which far surpasses the aged queens; still, zealously preserved by some with all the orthodox clipping of wings, but which is neither commendable nor necessary where young queens are kept. The system of keeping young queens only in stock and large hives has, like the tiering hive, been from time immemorial successfully and systematically carried out in Scotland.

DOUBLE CASED HIVES,

For a country where they have to be moved about these are very ill adapted, and give no advantage whatever to bees or to bee-keeper. The single-cased hives are in every respect the best. Where small supers are used, a case about a quarter of an inch larger than the hive slips over the supers and protects them from cold or damage from jarring. Supers, especially at the Heather, ought to be the best protected, and with such hives I often have two and three tiers of supers filled, while the body of the hive is not completely filled. In fact, this seems to be the wishes of the bee, to have some unfilled space at the bottom of their hive, and shows how contrary to the bee's nature it is to crowd the bees into little space, or to fancy eking will prevent swarming. The construction of our hive is so simple that preparing them for moving is but child's play, and safety to the bees and people is insured. No bee can escape, and from the shallowness of the combs none can collapse, even although the road is rough, while from thoroughness of ventilation no bee is injured, and that plague foul brood, brought on by the stifling system, is never encouraged or started. Other details will be given in future issues.—A LANARKSHIRE BEE-KEEPER.

BEEES AND THE WEATHER.

IT may be some consolation to northern bee-keepers to learn that bee-keepers in the "sunny south" have no better prospects of a honey harvest than they have in the north. From the 20th of May till the 4th of June we had bright fairly warm days, and the more forward stocks were working well in supers, two of my own having well filled forty-two 1 lb. sections each, but at the latter date had no sealed honey. Since then we have had rain on twenty-three days, amounting in all to 5'35 inches, and a most remarkable absence of sun. It is needless to say that the bees have stored no surplus, but breeding has gone on, and swarming could not be prevented, even in the few short blinks of sunshine we have had. On the night of the 10th we had a strong cold north-west wind with rain, the former continuing all the day; the sun struggled through the drifting clouds occasionally and tempted the bees out, and they have perished by thousands. The thermometer was down to 39° that morning, and to 44° on the morning of the 12th. The wind has moderated, the barometer is rising steadily, and we hope for a favourable change. Dutch Clover is more plentiful than I ever remember having seen it, and if we have sunshine now we may yet have our empty supers filled.—A SUSSEX AMATEUR.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Gardener Leaving (Reading).—If the house you live in belongs to your employer and you pay no rent, it is regarded as part of your wages, and you can only remain in it after your term of servitude

expires by permission of the owner. No charge is made for answering questions in this column to regular subscribers.

Melons Failing (Hall).—Are you sure the soil is not dry next the slates over the hot-water pipes? We suspect it is, and possibly the atmosphere may be too damp. Dig down to the slates, and if the soil is dry there make it moist in the best way you can, and raise the night temperature 5°, rather more than less, and continue the application of lime when gumming appears. Perhaps the soil is not so firm as it should be.

Photograph of Rose (C. P.).—We thank you for sending the photograph, but no one knows better than yourself how inadequately it represents the plant and blooms. This is, as you suggest, no fault of the artist, but is due to the subject and position. A Rose on a wall is about as difficult to "take" well as a house of Grapes, and nothing like justice is done to one out of ten of either by a photographer, however competent he may be in his work.

"Adam's Needle" (Amateur).—The plant of which you send flowers under the above name is *Yucca gloriosa*, a native of America, but known in this country for nearly 300 years. It is by no means uncommon to see this *Yucca* in flower, though it does not flower quite so frequently as some other species. The plant is not likely to die if it is in good soil, though it may suffer a little if it has a very large head of flowers. In any case suckers are produced freely, that will enable you to perpetuate it. The term *Aloe* is often applied to *Agave americana*, but it is really a distinct genus.

Melons (D. C.).—We have never seen Melon leaves in a more filthy state than those before us. They are infested with the black and green aphides, and the leaf surface is taken possession of by a fungus, hence the incrustation. All such leaves should be cut off and burned, and if the whole of them are equally bad the plants should be destroyed, for they are beyond recovery. If there are a good number of fairly clean and healthy leaves, sponge them with one of the insecticides advertised in the Journal, but we suspect the plants are ruined. When the house is empty it must have a thorough cleansing in every part, or you will have the same trouble next year.

Learning Gardening (C. C.).—Gardening cannot be better learned by an earnest student and worker than by reading attentively the articles and answers to correspondents in this Journal, taking note of information that is given on various subjects, comparing it with the work in hand, and storing it for future use. Thompson's "Gardener's Assistant" is a standard work on gardening, but the price is about 35s., but an enormous amount of information is contained in the thousand pages of the "Cottage Gardener's Dictionary," price 8s. by post from this office. There are works on special subjects, but those named embrace nearly everything pertaining to gardening.

Mushroom Spawn (J. T.).—Your questions are unanswerable; indeed they are so peculiarly framed as to be scarcely intelligible. Every spawn brick is not equally permeated with mycelium throughout, and that fact alone does not permit a reply being given to your first question. A lump an inch square full of spawn suffices for insertion, and three of these for a brick, but every inch you cut or break up may not be full of spawn, hence useless. About 80° is a suitable temperature in the manure for the running of the spawn. We cannot tell you about the practice adopted by all the vendors, but all of reputed sell good spawn, and probably much better than you can make unless you have seen the entire process in operation. The nearer the spawn is obtained from spores the stronger it is, and the finer the Mushrooms produced under suitable conditions.

Rose Growths (Kittie).—In the first place you must be sure the strong growths from the base of your dwarf plants are Rose growths. We have seen such growths encouraged more than once, and a luxuriant mass of the Manetti Rose established. Some of the base growths are so luxuriant that they do not bloom in the autumn, and those that are very sappy may be topped when as high as the older growths. Others of medium strength that give promise of producing flower buds may be left for giving late blooms. The character of the shoots can be fairly determined on close examination and comparison. The basal growths of moderate strength and well ripened usually give the finest blooms next year, and it is a good plan to cut out weak growths after flowering, for admitting light and air to the stronger; but these should be kept as uniform as possible by topping, not allowing one or two to rush far ahead of the others and deprive them of a fair share of support.

Wiring Garden Wall (Wm. B.).—The best wire for walls and espaliers is No. 13. L.W.S. galvanised. The wires should be fixed in every alternate course of bricks, or about 6½ to 7 inches apart. For guiding the wires on the walls galvanised malleable eyes should be used about 6 feet apart, and they should put in quincunx—i.e., the first eye in the bottom row should be 3 feet from the end, then 6 feet, and the first eye in the second row should be 6 feet from the end. The eyes should not project more than three quarters of an inch from the wall, between that and half an inch being a proper distance. Both eyes and winders are made to project the wires 1½ inch from the wall, which is a mistake, as the trees do not thrive well with a space between them and the wall more than is necessary for tying purposes, deriving little benefit from the shelter and warmth of the wall. All the materials should be galvanised.

Peach Tree Foliage Turning Yellow (An Anxious Inquirer).—The cause of the foliage turning yellow is, no doubt want of water, and support of a nitrogenous nature. The border being well drained, bones and old mortar rubbish used freely, water would be required at

least once a week after the trees were in good foliage, as their roots ought not on any account to be allowed to become dry, but water ought not to be given until there is need for it, yet before the soil becomes so dry as to affect the foliage. Enough should be given to well moisten the border down to the drainage. As no manure is used in the border—a very wise plan—nutriment should be supplied as mulchings of short manure—not in excessive quantity, especially of fresh short litter, with the droppings from the stables. It is better to give a little and often rather than a large quantity at once. A mulching 2 or 3 inches thick is quite sufficient, just covering the surface when the fruit begins swelling after setting, and from that time forward adding a few fresh knobs weekly, so as to have the mulch about 3 inches by the time the fruit is well advanced in stoning. A sprinkling of soot, followed by a good watering, would do much to improve the colour of the foliage, or liquid manure, not too strong, may be given if the trees are not vigorous, each time water is required.

Earwigs (M. P.).—The following, chiefly extracted from Köllar, will perhaps meet your wishes:—"The Earwig (*Forficula auricularia*).—This well known insect, considered, without cause, as very dangerous to mankind, must find a place among those chiefly injurious to fruit and flowers. Its size varies according to its age and sex. When fully grown it measures 8 or 10 lines, including the forcep-like appendage at the end of the abdomen; its breadth is 2 lines. The body is light brown free from hair; it has very short wing cases, under which the wings lie concealed, folded both longitudinally and transversely. Its usual habitats are under the bark of trees, in the hollow stems of trees, in rolled up leaves, and under stones. The female sits upon her eggs like a hen and broods her young. The only certain method of destroying earwigs is by catching them, which is best effected by hollow tubes laid here and there in orchard and flower beds. The common Reed is fit for this purpose, but the hollow stem of the Sunflower is even more so, as the insects are eager in the pursuit of the remains of the sweet pith. They are also easily caught between the folds of paper, or in pieces of cloth and linen laid on the ground. They creep into these traps in the morning after their nocturnal rambles, and may easily be shaken out and killed at any time of the day. Some amateurs of Pinks and Carnations place the feet of their flower stands in vessels of water, which prevents the earwigs from creeping, but not from flying upon the plants, for the earwig has wings."

Cucumbers Dying (R. T.).—The roots you have sent afford no signs of the disease that is caused by nematoid worms or vibrios, and we do not think they have been so affected. As the plants have failed for many years we suspect some error in management, either in regard to soil, watering, atmospheric moisture, or ventilation. If the plants root freely in rough rich loam, and are adequately watered, also that top-dressings of rich composts are applied as often as roots protrude through the surface, Cucumbers usually grow vigorously if properly attended to in other respects. If the plants have not been well fed in the manner indicated, and have also been allowed to bear all the fruits that set on them from the outset, they have been prematurely exhausted. We have seen many collapse through overbearing them when young and not encouraging the production of fresh roots for appropriating the food supplied. As you say nothing about the stems gumming or cankering, we assume these evils do not exist, and as the roots are clean and the stem has a starved appearance, we attribute the failure to inadequate support. Liquid manure will not compensate for the absence of new roots, and these can only be encouraged by frequent top-dressings of rough soil and manure kept regularly moist. If you can send us further information we will readily consider the case again, but with the sample and data before us we can arrive at no other conclusion than that the plants succumbed through overcropping them when young and inadequate support.

Troublesome Insects (Thomas O.).—The specimens marked No. 1 are insects of the centipede family, the species being known as *Geophilus subterraneus*; at present they are immature, but in autumn, when they have become larger, they change their mode of life. We then often find them out of concealment, crawling on paths or amongst herbage, apparently with the object of preying upon other insects, and being occasionally luminous in the dusk they are sometimes called glow-worms. This, and similar species, are apt to be more troublesome in moist seasons. Gardenias are particularly liable, it seems, to the attacks of insidious foes such as centipedes and scale. Many centipedes may be caught and killed by setting traps for them of slices of Carrot, Potato, or Apple buried loosely in the soil. The application of soot or lime is also destructive to them, and in the case of delicate plants they may be watered with a clear solution of the latter. When these fail petroleum has been tried as an application to the roots of plants, about 1 oz. to gallon of water well agitated and mixed, but this requires care in using. No. 2 contains the larva or grub of a small weevil, the red-legged or Apricot weevil (*Otiobius tenebrioides*), which comes out later than the larger and even more troublesome *O. sulcatus*. The perfect beetles infest the young shoots and leaves of various fruit trees during the spring, and their progeny lie at the roots of shrubs, such as the Currant, also visit Strawberries, and occasionally vegetables, as in your case. They are difficult to reach, and not easy to kill when in the larva state as sent. Diluted ammoniacal liquor and a solution of salt have been found serviceable, and recently a decoction of quassia chips in which some soft soap has been dissolved.

Peach and Fig Diseased (Sixteen-years Subscriber).—The appearance of the fruit indicates too rich and open soil, with a deficiency of calcareous matter. The decay is resultant of disorganised tissue,

predisposed by impure sap. The only remedy, and it is infallible, is to lift the trees so affected as soon as the growth is complete and the buds and wood sufficiently matured, but whilst the leaves are upon the trees, and lay the roots in fresh material, or the old material to which an addition is made if the soil be light of clayey marl equal to about a fourth, using it in as small pieces as practicable, and in any case a sixth of old mortar rubbish passed through an inch sieve. The roots should be laid in the compost, which must be well incorporated, nearer the surface, and particular care should be taken to preserve those that originate from the base of the stem and are of a fibrous character. All the roots should, if possible, be within a foot of the surface, placing in layers with the soil pressed firmly about them, the topmost not being more than 3 inches deep. The border must be efficiently drained. A border 24 inches deep is ample, and if it be less by one-third the width the trees occupy the roots will be more under control, and better than in a large mass of soil. Done at the time indicated the trees will make fresh roots before or with the fall of the leaf, and these being preserved by a mulch of short rather fresh stable manure 3 inches thick, nutriment will be afforded of a character insuring a good set, and satisfactory swelling and stoning, which effected, judicious after treatment will bring the crop to perfection. The Figs are decayed at the nose or apex, which is usually a result of insufficient ventilation, the house being kept too close, moist, and cold. To insure Figs ripening perfectly they require a circulation of dry warm air, moisture being kept from the fruit after it begins ripening. It is particularly desirable to prevent moisture being deposited on the fruit at night, as when that occurs and air is not given sufficiently early to dissipate it before the sun acts powerfully upon the house, the fruit is made to shrivel at the eye and soon decays, being accompanied by a fungus, as in the examples sent.

Mildew on Strawberries (J. D.).—We have examined the plants and find them seriously infested with mildew, and to this we attribute the non-swelling of the fruit. The roots of the plants that have been grown in pots are quite healthy. There is nothing wrong with them. Mildew is much more prevalent in some districts and seasons than others, and the conditions in your case have evidently been favourable to its increase. There is no doubt whatever that sharp currents of air passing through front ventilators directly to the plants render them liable to the attacks of the parasite. It is the same with Roses, and some cultivators on that account scarcely dare open the front ventilators early in the season in gardens where mildew is prevalent. Very cold water given to plants on warm and bright afternoons is also calculated to result in the attack of the pest, because both the cold water and cold currents give a temporary check to the sap movement, and stagnation in that respect is favourable to the germination of mildew spores. The plant from the open ground is exceedingly luxuriant, and the leaves do not appear to have been able to elaborate the sap, which would thus be in a more or less impure state, and on that account favourable for spore germination. Cold night winds and bright sunny days alternating would be likely to encourage the parasite for the reasons stated. We should try the clean runners, but increase chiefly those varieties that best resist the mildew. The under surface of the leaves are first and chiefly attacked, because the cuticle is thinner and more easily penetrated. It is to the reverse side of the foliage, therefore, that the soft-soap and sulphur mixture should be applied, and even if the work is a little tedious it is worth doing. The worst affected leaves cut off and burn. They can be of no benefit to the plants, and will mature myriads of spores. It does not follow that the attack will be so virulent another year. You will find some varieties succeed better in your soil than others, and these should be most extensively grown. We know a garden in which President is worthless, and the soil is very similar to that with which you have to deal. In another garden, where the soil is lighter and less rich, it is one of the most profitable varieties. Vicomtesse Hericart de Thury is one of the hardest in foliage, and likely to answer your purpose. We know the garden very well, with its sharp slope and strong soil, and are not much surprised that mildew is so prevalent in it this year.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (W. H.).—The Strawberry is Carolina Superba, which is hardier and usually a better bearer than British Queen.

Names of Plants.—We only undertake to name species of plants not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (O. W. D.).—Specimens for naming require to be very carefully packed to ensure their reaching us in recognisable condition. Those sent were so dried and crushed that it was quite impossible to determine them. Packed in small tin boxes with a little damp moss they would travel safely. (J. P.).—Without flowers or leaves the plant cannot be recognised, but from your description and the material sent we should think it is *Geranium pratense*. (J. J.).—The weed known as "Fat Hen," of which you send leaves, is *Chenopodium album*; the red-leaved plant is *Atriplex hortensis*, and the Orchid *Aerides expansum*. (W. B.).—*Gloriosa superba*. (R. S. T.).—1, *Reseda lutea*, the wild Mignonette; 2, *Chrysanthemum Leucanthemum*, the Ox-eye Daisy.

COVENT GARDEN MARKET.—JULY 18TH.

THE present dull weather is considerably affecting supplies, our market presenting anything but its usual appearance at this season of the year. Prices remain unaltered.

FRUIT.

PURE SEED.

THRESHING machines since they came into general use have caused much mixing of different sorts of corn, simply from the want of care in cleaning the drum between the using it for threshing different corn stacks. No doubt, too, there has been much carelessness about seed corn generally, yet it is equally obvious that the careful selection of seed is an important factor to success in farming. As a means to so desirable an end it is well, now that corn is sufficiently advanced in growth to show its true character, that a close inspection should be made, and all "rogues" got rid of. A sample of corn that is pure and of high quality invariably commands more attention from buyers than inferior mixed samples, no matter whether it is required for seed or food. Seed merchants charge fancy prices, and get them too, for pure seed; and therefore it is clearly to a farmer's advantage to help himself as much as he can in this matter.

Close inspection of growing crops as they approach full development enables one to ascertain something about the relative value of different sorts. Such knowledge is not, however, to be regarded as conclusive, rather should it be joined subsequently to that sure and final test of weight and measure when the corn is threshed after harvest. Some of our most showy corn in the field does not pass the weight and measure test well. For example, Giant White Wheat is one of the most attractive sorts we have ever had, and there are few finer sights on a farm than a field of it under good cultivation in the present month. But after a thorough trial of it upon four of our farms we have discarded it altogether, for the bold showy crop is misleading, being deficient both in weight per bushel and quantity per acre—both serious faults for which quality alone will not atone.

Champion White Wheat from pure seed saved at our home farm bids fair to take the lead this year; we have it at all of our farms, and it is alike good on mixed soil and heavy land. What we really wish for is a White Wheat that is at least equal if not superior to any other Wheat in growth of straw; in quantity, weight, and quality of grain, and which is hardy, robust, and not liable to disease. It is always worth a little more per quarter than Red Wheat, and if that little only amounts to 10s. per acre it is quite worth trying for. Of Red Wheat, Defiance, Scholley's Square Head, and White Chaff Red are the sorts we have in cultivation this year. The first two are from very pure samples, and the results of the trial will enable us to decide whether it is worth while growing all of them again. On one farm we have an interesting study in a 30-acre piece of Wheat consisting of 10 acres each of Champion, Defiance and Square Head. On another farm we have upwards of 100 acres of the same sorts of Wheat, but the fields do not lie so well together for comparison.

Of Barley we used seed from excellent samples for this season, of which perhaps the best is a pure sample of Golden Melon from light land. We have also a good selection of Chevalier, and are trying to do still better by sowing a small field of Webb's Kinver Chevalier at the home farm for a supply of seed next season for the other farms. In all we have several hundred acres under Barley, and the importance of having the best only is obvious when we recall the fact of prices ranging last season from 20s. to 40s. per quarter.

The same principle equally affects all other crops, and its importance has a golden significance to the great seed firms. Not only do they find it answer to introduce new and improved sorts, but also pure selections of old ones. In nothing perhaps has greater improvement been effected in this manner than in forage crops. Permanent pasture is now gradually becoming as select and highly cultivated a crop as any other, but the cultivation of pasture is still only an idea, and not an accomplished fact with many farmers. Take a really well-cultivated pasture consisting of Foxtail, Cocksfoot, Timothy, Rye Grass, the Fescues, with a fair proportion of Clover and Yarrow, and the crop will be alike superior in nutriment and bulk to an old pasture of indigenous Grasses. For bulk of crop, Rye Grass and Cocksfoot, under a system of alternate husbandry, are perhaps superior to most other forage plants—certainly to all other Grasses—and their nutritive properties are shown by analysis to bear favourable comparison with other Grasses.

What we really want for the land is thoroughness in every detail of culture. We may procure pure seeds at a high price, but the money will be wasted if any other link in the chain of cultivation is missing. Drainage, mechanical division, deep cultivation, cleanliness, are alike indispensable to success, and not one of them must be wanting to insure it so far as it is in our power; for, alas! we cannot control the weather, which must be seasonably genial to put the crown and finish on our work.

WORK ON THE HOME FARM.

As we write farm work is almost at a standstill. We have thirty acres of meadow hay in cocks, and much Clover hay still out. Day

after day has rain fallen, with the exception of the 8th and 10th and part of the 9th. Sunday, the 8th, was a bright hot day. The 9th opened fine, and we were able to clear several acres of meadow hay, and prepare many more for putting in cocks, but just as we had got the horse rakes in full swing and a few cocks made, down came the rain. On the 10th, by a free use of hand rakes, tedders, and horse rakes, we were successful in getting all the forward hay into cocks, and fortunate indeed were we to be able to do so, for much heavy rain has fallen since then, and it really appears that we are likely to have a repetition of the wet summer of 1879. Well, we made some good hay that year, and do not despair of doing so now. But haymaking in such unsettled weather is costly work, and happy men are they who are able to convert the crop into silage. We require large quantities of hay for sale, and so must do our best to obtain it.

No doubt the rain has done much good to light land crops, but all corn crops now require bright weather. The Wheat is in full bloom, and Barley is fast coming into bloom also; if now we can only have a favourable change to develop and ripen the grain, we still hope for a yield of a high average. Root crops are of course flourishing in such exceptionally favourable weather for them, and young layers of mixed seeds, Clovers, Sainfoin, and Lucerne are all thriving. Cattle Cabbage, and Kale too, should be exceptionally good, but the weather has been too cold for Maize to make really free growth.

With more settled weather every effort will be made to save the remainder of the hay, and other work is so forward that every man and horse can be used for this important work. Care must be taken to have all haycocks well shaken out and the hay thoroughly turned and dried before being carted to the rick, for however dry it may feel, some moisture always ascends to it from contact with the soil in such heaps, and without subsequent exposure to sun and air there is much risk of mouldy hay in the rick.

WE are requested to state that the only prize medal for appliances given at the Kennel Club Show, recently held at Barnes Elms, was awarded to Spratt's Patent, Limited.

SEED STANDS AT NOTTINGHAM.—The splendid and admirably furnished stands of Messrs. James Carter & Co., Messrs. Sutton & Sons, Messrs. E. Webb, Oakshott & Millard, and others we are informed constituted an important feature at the Royal Agricultural Society's Show recently held in Wollaton Park, Notts, but we have not space for detailing the exhibits in the midst of the Rose-showing season.

OUR LETTER BOX.

Scouring Calf (G. R. S.).—A calf so much reduced by scouring as to be almost a skeleton and unable to rise should be destroyed and an end put to its misery and suffering, for such a case is hopeless. From the extraordinary remedy suggested by your cow leech, we should hardly consider him qualified to attend to the diseases of animals. Generally speaking, scouring is caused by foul water; coarse, indigestible, unwholesome food; by long fasting and subsequent gorging, and by exposure to damp and cold. Our highest veterinary treatment consists in judicious feeding, nutritive food, restricted water supply, laudanum and ether or chlorodyne to abate spasm and pain; iron, acids, and bitters to promote the healthy tone of the weakened membrane, and comfortable protection from wind and weather. Such general advice falls clearly within our province. Specific remedies can hardly be stated without actual examination of an affected animal, and therefore we say, Do your best for other animals with food and shelter, and in every case of illness where simple remedies fail, at once call in a duly qualified veterinary surgeon.

REMARKS.

8th.—Fine, but without bright sunshine.
9th.—Bright and fine till noon, cloudy afternoon; slight shower in evening and night.
10th.—Fine, with occasional sunshine.
11th.—Strong wind and heavy rain in small hours; day generally overcast, with remarkably low temperature.
12th.—Damp showery morning, cloudy afternoon and evening; very cold.
13th.—Bright and fine; much warmer.
14th.—Oppressive, and frequently threatening; shower in evening.
A dull, damp cold week, the 11th and 12th being especially not worthy for their very low temperature, that of the 11th I believe to be without precedent; not that the minima were exceptionally low, but the 9 A.M. and noon temperatures and the maxima, all the latter being frequently exceeded in January.—G. J. S. MONS.

THE HARDY FRUIT MOVEMENT.

TWO notifications have been made recently which indicate the existence of a desire that the fruit-producing resources of the kingdom should be developed, that obstacles to that end should be removed, and information on the whole subject elicited and disseminated. The first of these notifications is that relating to a conference of fruit growers to be held at the Crystal Palace in connection with the fruit show that is there held in September; the second the official announcement that an Apple and Pear Congress will be held under the auspices of the Royal Horticultural Society in October. There is room for both the projects being carried out, indeed it is questionable if either the one or the other of them could of itself do what is needed in discussing the whole subject of fruit culture in its commercial aspects and routine matters connected therewith, in a manner that would arouse public attention. It is quite time for something more than "showing" to be done, even at the Crystal Palace, if any substantial benefit is to accrue to others besides the winners of prizes; and it is still more incumbent on the part of horticultural societies to render their periodical gatherings instructive as well as attractive; and if one more than the other should lead the way in a departure from the system of showing, and showing alone, surely it should be the Royal Horticultural Society.

When the proposed conference of growers at the Crystal Palace was mooted, a number of persons interested in the subject of fruit culture at once gave their adherence to the project. It was felt, as if intuitively, that something of the kind was wanted, and that an opportunity for free discussion on a matter of great public importance had not hitherto been afforded in any systematic manner. The Committee appointed to make arrangements for carrying out the idea, and for formulating a method of procedure, will doubtless devise a programme that will open up a discussion of a distinctly beneficial tendency, and while no possible harm can be done by the reading of papers and an interchange of views thereon, it is conceivable that substantial good will result from the deliberations. It may be well, and is certainly desirable, in a reference to the projects indicated to banish all ideas of rivalry or opposition between them. Such ideas cannot be entertained by men who take a broad view of the subject, and judge it on its merits entirely apart from personal preferences and prejudices. The Crystal Palace gathering, that will be supported by Fellows of the Royal Horticultural Society, members of its Fruit Committee, and at least one of its Council, cannot possibly weaken the movement of the Society, but it may materially strengthen it. The first named effort will act as a stimulant, and the experience gained will be available for use at the second, if based on the same lines, and if not, the world will gain by the two endeavours, while the former will bring the latter into greater prominence. A good deal may be done in September in arousing public interest on a great question, and then the Royal Horticultural Society may do a great deal more if the proceedings are conducted on a broad, popular, practical basis in October, and onwards as circumstances suggest.

Rightly or wrongly—and the fact is mentioned without suggesting a semblance of reproach—a feeling is growing that the resources of the still great Society are not being applied in the best interests of the country or of itself. The medals awarded for groups of

plants may be merited so far as the collections are concerned, and if medals were as plentiful as Blackberries there would be some to spare to be differently applied, and possibly not to a less useful or legitimate purpose. But the number is limited, and the authorities might do worse than consider whether a few of the honours at disposal could not be advisedly diverted from the orthodox channels. The vast majority of them are given for groups of plants, not for new plants possessing striking features entitling them to the distinction, but to collections of old and new plants on sale, and for which the exhibitors gain in other ways. Probably if an investigation were made it would be found that ten medals are granted for plants to one for fruit or vegetables; or, in other words, the ornamental section of gardening is rewarded at the expense of the useful. The disproportion is, perhaps, even greater than suggested, in which case there is all the greater reason that the lost balance should be restored.

It may be urged that medals would be granted for fruit and vegetables if collections of them were exhibited worthy of such recognition. Possibly, but not certainly, otherwise a most interesting and instructive collection of Peas recently exhibited by Messrs. Veitch & Sons at Westminster would have had something more than a vote of thanks and cultural commendation, but consisting of Peas only, and not of border flowers or nicknacks, it was *passé*. That, however, is not the point. The established principle appears to be only to grant medals to something "exhibited," articles grown, or bought or borrowed for the occasion, and which can only be staged by a limited number of individuals, who win them yearly with duplicate collections, or practically so. Dishes of the finest fruits and vegetables are imposing, and give pleasure to persons interested who inspect them, while the produce is as creditable to the growers, and these deserve recognition equally with exhibitors of plants and cut flowers; yet in the case of fruit especially, as a good gardener remarked the other day, "Grand dishes may mislead, and have misled, because spectators have been fascinated by them, taken the names of the varieties, bought trees the habits and bearing capacity of which they knew nothing, occupied space with them for years profitlessly, the result being that the planters wished either they had not seen the tempting specimens, or that information of the nature suggested had been supplied for their guidance." It would seem that something more is needed than staging so many varieties, whether medals are awarded for them or not. The best fruit producible, combined with the best knowledge attainable, appear to be the desiderata; and if both cannot be had together it is conceivable that the knowledge without the fruit would be of greater service than the fruit without the knowledge. Might not, therefore, a great good be done and much wider interest created in the work of the Royal Horticultural Society if a reasonable number of medals were set apart for the best essays on prescribed subjects relating to fruit and profitable land culture; these to be published without delay, and before the interest in the work vanished, for the benefit of the community?

If the Royal Horticultural Society were to devise something of that kind, and offer rewards for knowledge founded on experience and observation, a new and wide field would be opened, and men of ability in distant parts of the country who cannot "stage" material produce in London, could, and doubtless would, impart information that, if disseminated, would be of greater service to the nation than bald records of medals awarded for groups of miscellaneous plants or what not, that few are interested in beyond the recipients, and which not one person in ten thousand can see.

The subject now more immediately in hand is fruit, and in view of the coming Congress, if, in addition to samples of Apples and Pears, also independently of them, medals were offered for essays on specified subjects, to be selected by the Fruit Committee for consideration and ratification of the Council of the Society, it is not unlikely that more solid information would be forthcoming than by any other means, and that would command greater atten-

tion, and meet with wider acceptance than the records of a show could possibly do, however extensive and varied it might be. The reading of the prize essays thus obtained, with the discussion on them, during the period of the Congress at Chiswick, would enormously enhance its importance, and the public would be quick to see that the Society was engaged far more appropriately and beneficially than in the hackneyed work of "showing," and the Crystal Palace Conference would act as an appetiser to what ought to be a still greater and more important event.

VEGETABLES FOR EXHIBITION.

SELECTIONS FOR SUMMER SHOWS.

THAT many good vegetable growers err greatly when selecting their dishes for competition I well know, having bought my learning in that respect years ago, and others are doing the same every season. In most schedules the prizes are offered for a collection of eight kinds of vegetables, distinct, or the number may be two less or more. When it is stated that distinct kinds are required this means that no two varieties of Potatoes, Onions, or any other species will be allowed, infringing this rule justifying the judges in disqualifying the collection. There should always be a limit to the number of dishes, but if the prizes are offered for a collection of not less than, say, six varieties of vegetables, a hundred dishes may be staged, these including as many varieties of each kind as the exhibitors choose to put up. In such unsatisfactory competitions those who have charge of a large garden literally swamp their less favoured rivals. I must plead guilty to having won prizes in this way, but I should have been much prouder of winning with a fixed number of dishes.

Any time during the summer, and more especially during August, when so many shows are held, there are usually plenty to select from; but what I term a model selection would consist of Potatoes, Tomatoes, Cauliflowers, Globe Artichokes, Peas, Carrots, Onions, and Cucumbers. If four more are wanted add Kidney or Runner Beans, Vegetable Marrows, Turnips, and Broad Beans, and in reserve Celery, Cabbage, Beet, and Mushrooms. No one, however, should think of rigidly adhering to, say, the first six or eight dishes unless all were extra good. What is shown should be as nearly perfect as possible; and if, for instance, Carrots are bad, leave them, and substitute either Turnips, Kidney Beans, Marrows, or any other kind that may be superior. The same remark holds good with all other kinds excepting Potatoes, these being generally considered indispensable. Cabbage ought to be the last to fall back upon, as it cannot be considered of much value in the summer, nor do I attach much value to extra early Celery, as unless it is very good it does not count for much in a limited collection.

Some schedules state the number of specimens to form each dish, and where this is the case the greatest care should be exercised. Trickery of all kinds ought to be avoided. Never, if it can possibly be avoided, include roots, or specimens of various sizes, nor two varieties in one dish. Those which invariably please the judges are of uniform age, size, and colour, and in most instances medium-sized examples are preferable to those either very large or rather small. From nine to twelve Potatoes are usually sufficient for one dish, and these should be of good size, clear skinned, shallow-eyed, and without a trace of disease in them. If they are to be sent or carried some distance a few surplus tubers must be packed, as during the bad seasons some of those apparently free from disease may have developed it in the journey. All should, directly they are lifted, be carefully sponged clean, taking care not to bruise the skins in any way, and directly they are dry cover them to prevent greening. If packed for a long journey, wrap each tuber separately in paper and pack closely in a box. Fine tubers of the old Snowflake type, such as Cosmopolitan, Sutton's Seedling, Cole's Favourite, and Woodstock Kidney, always look well among a collection of vegetables, but I would on no account include International Kidney.

Tomatoes give quite a finish to a basket or tray of vegetables, and count well when judging by points is resorted to. The Perfection type, or the round, smooth-fruited varieties "take" best, and all should be nearly of one size, not over-ripe, and good in colour. They cannot well be too large always provided they have no ugly centres. As Tomatoes travel badly, and are of much less value when bruised, each fruit ought either to be wrapped in a square of tissue paper, and then bedded in moss, or strips of cotton wool can be wound round each Tomato, and all be packed closely together. In any case pack them stalk end downwards, and let them rest on a springy bed of moss or cotton wool, the lid closing down tightly on more of the same material. They keep longest when cut before they are really ripe, and will colour in a warm room nearly as well as they do on the plants.

Cauliflowers, if really good, are also of great weight in a collection, but those old much-greened, and, perhaps, caterpillar-eaten specimens sometimes seen at shows, had far better been left at home, and another good kind substituted. Large specimens ought not to be shown unless the "heads" are quite solid and white, as those nearer the size of a 2-lb. Melon, if quite fresh, will surpass others larger but less even. They may be kept several days by having the leaves tied tightly over them, this being preferable to lifting and storing in a shed. Preserve as many leaves as possible until the show tent is reached, this preserving the hearts, and which are easily bruised and become discoloured even in a short journey. Good-sized quite fresh Cauliflowers will stand and look all the better for rather severe trimming when being staged, but in the case of small or rather stale samples a few of the small inner leaves should be preserved. As they are liable to green quickly it is advisable to cover Cauliflowers and other white vegetables with paper till clear-out time arrives.

Globe Artichokes if shown in good condition secure the maximum number of points. The green variety is the best, but we include good samples of the Purple Globe rather than have no Artichokes in a collection. Very young or very old heads are unsuitable, neither being of much value. What are wanted are large, fully open, yet quite fresh heads, or those with thick succulent scales. It is the latter that the judges should test with the thumb and forefinger, and if found hard and dry be discarded. Six or nine heads are none too many, and these ought to be cut with long stems, especially if the collection is arranged in a basket.

Peas if fresh and good are entitled to a place in quite small collections. The pods ought to be straight, rich green in colour, well filled, yet not too old. Mere windbags are of no use, as Peas ought always to be tested by opening if not actually tasted. Telegraph, Telephone, Stratagem, Duke of Albany, Evolution, Jubilee, and Prodigy are all fine exhibition varieties, none failing to fill well, and for the later shows Ne Plus Ultra is also good. Gather Peas while the dew is on them, and carefully lay them in shallow boxes. When roughly handled the bloom is rubbed off them, and they present a spotted fringed appearance. If they have to be taken a considerable distance, pack the pods closely, the layers being separated by tissue paper.

Carrots when of good colour and well selected much improve the appearance of a collection, and I never like to omit them. The Nantes, Veitch's Model, Champion, and other superior Horn varieties, if of full size, are the best for the summer shows, and later on fine samples of the New Intermediate are hard to surpass. It is of importance that the roots be all of one size, clear skinned, and richly coloured. Quite small fibres and much of the tops may be trimmed off with advantage, and the roots be carefully sponged clean, dried, and then wrapped separately in paper.

Onions are considered indispensable by some exhibitors of collections, but I do not admit this. If good they ought to be included, not otherwise. Any time up to September the autumn-sown Tripolis may be shown in collections in preference to those of the White Spanish type spring-sown. The white-skinned varieties, notably Early White Naples, Giant White, or White Elephant, are more attractive in appearance than the Roccas, the latter being reserved for the class for heavy Onions. All loose skins and the roots should be trimmed off and a sponging in clean water be given. Select those with rather flat tops and well-rounded bulbs, and stage them with the tops downwards. Spring-sown Onions ought to have small necks, be ripened as much as possible, the straw-coloured skin looking well. Trim off the loosest skins only and the roots, and sponge them clean. These should be staged with the tops uppermost, but seeing that the judges cannot resist handling even Onions, give the preference to well-rounded bulbs with neat necks.

Cucumbers are usually included in good collections of vegetables, and if young, very straight, even in size throughout, and with short necks, they count well. At one time a brace was considered ample for a dish, but nowadays, in some districts at any rate, large heaps are put up. At first sight large heaps of vegetables of any kind attract attention, but with experienced judges have but little weight unless the whole of the produce is of good quality. Always, therefore, stage enough to avoid meagreness, but never put up large heaps of mixed quality. Carter's Model, Tender and True, and a good selection of Telegraph are all good for competition, both in collections and single classes.

Kidney and Runner Beans are of about equal merit, but the latter, if at their best, are the most imposing in appearance and may be preferred. Neither can be too long and broad provided they are not too old. They ought to be perfectly straight, rich green in colour, and should snap readily when tried by the judges. The latter do not always take the topmost pods, and although it is advisable to finish off the heap with some of the best, the rest

should not be old and tough. Canadian Wonder and Negro Longpod are the finest Kidney Beans, and amongst the runners there are none to surpass Ne Plus Ultra, Carter's Jubilee, Girtford Giant, and the Czar.

Vegetable Marrows may safely, if required, be given a place in a collection of eight kinds, though not if all those already commented on are in the best condition. On no account should full-grown Marrows be shown, either in a collection or single dish. What is wanted are two or more fruits of the Long White, these being about 9 inches long, of one thickness throughout, very fresh-looking, and without a blemish on them. A brace that varies in age, size, or form ought not to stand any chance whatever against specimens that I have described. Young Marrows are easily bruised, and each ought therefore to be wrapped up separately in soft paper, even if only a short distance has to be traversed to reach the show ground.

Turnips during the summer months are seldom fit to be included in a limited collection, but if quickly grown clean roots of Snowball or Veitch's Red Globe are available they would count well. A perfect root would have only a one mouse-tail-like tap root, which ought not to be cut off, and any that need much trimming are of little value. They may be near the size of a cricket ball or rather less, should have the leaves shortened, the bulbs carefully washed clean, and each packed separately in paper, or they may soon disfigure each other.

Broad Beans cannot be classed very highly, and are seldom included in limited collections after July. The very finest is Carter's Leviathan, and a well selected number of straight, and not very old pods 12 inches long and upwards are not to be despised. The Seville Longpod also grows to a good length, and handsome dishes of it are frequently shown. Beet is scarcely telling enough in small collections, but ought to be included in unlimited collections. For the summer shows Carter's Crimson Ball, a superior form of the Egyptian or Turnip-rooted, is to be recommended, these being selected, cleansed, and staged exactly as advised in the case of Turnips. Celery, as before stated must be extra fine and well blanched, if included during July or August in a collection of eight kinds of vegetables. Wright's Grove White is sometimes seen in good condition at summer shows, and the Incomparable Dwarf White is also suitable for early work. Grove Red, Standard Bearer, and Sulham Prize are all shown well at different places towards the end of August. Celery must not be trimmed very hard, and ought to be washed quite clean. If Cabbages must be included in a collection, select medium sized conical heads in preference to very hard overgrown samples too often seen at shows. Veitch's Earliest of All is fine for exhibition, and the Heartwell Marrow is also good in every respect. Mushrooms must be very fresh and even in size, or they are no good at the summer shows, nor should Parsnips be shown unless in unlimited collections, or in single dishes. They ought to be very clean and straight. Lettuces are a very poor substitute for any of the preceding vegetables, but are often shown in single classes. Anybody's Superb Cos, or a good selection of Paris White Cos, is hard to beat, and Veitch's Perfect Gem is the best Cabbage Lettuce for the summer shows. Lettuces should be lifted, the Cos varieties being previously tied up, but not trimmed in any way, and have some moist moss bound about the roots. When cut for exhibition these soon flag badly. Never select any on the point of bolting, as these get worse after a short stay in a warm tent.—EXHIBITOR.

GARDENERS' ORPHAN FUND.

At the conclusion of the first year of the above it is a source of gratification to me to review the success which has attended our efforts, and which is due to the hearty co-operation of all concerned. I take this opportunity of returning my personal thanks to all associated with me in this matter, and also to the many gentlemen who have undertaken the office of local secretaries, and worked so zealously in the cause. The dinner, as is now well known, was equally a success—thanks to the numerous kind contributions of fruit, plants, and flowers. The room and tables presented an appearance which called forth unqualified expressions of admiration from the most competent and impartial critics.

It now affords me no small degree of pleasure to be able to state that we are commencing the second year equally well, being empowered, as I am, to announce that Mr. Sherwood (Messrs Hurst and Sons) in token of the interest he takes in the movement, has generously offered to place an orphan upon the fund at his own expense in accordance with Rule 12, thus increasing the number of recipients from ten to eleven. The name and particulars of the annuitant will be announced in due course.

It would afford me, and I may add the Committee also, much pleasure if any other gentleman blessed with an abundance of this

world's goods were to emulate this noble example. I can only say that there are plenty of deserving applicants to whom such a favour would be of the utmost service and benefit.—GEO. DEAL, *Chairman*.

PROPAGATION OF CONIFERS AND SHRUBS.

It is not often that gardeners in private establishments undertake the increase of trees, shrubs, and Conifers, but the propagation of many kinds by means of cuttings is easy, as they can be readily rooted and quickly grown into neat little bushes. A cold frame is all the protection required in the way of glass, but it is better if two smaller ones can be appropriated instead of one of the same size as the two, for the reason that some sorts require a longer time to root than others. Those that need more time can have the protection of the extra frame, while if the plants are kept together at the time of insertion, the early rooted plants can be transferred to other positions some months before the latest varieties. The size of the frame must be regulated by the requirements of the cultivator.

A shallow frame answers the best, for the reason that when new growth commences it is not drawn up weakly through being so far from the glass. The bottom of the frame should be covered with coal ashes, thorough drainage being essential. Over this have a layer 2 inches thick of decomposed horse manure or half-decayed leaves, into which the roots penetrate, as the soil clings better to the roots when manure or leaf soil in a rough state is present. Over this lay the soil 3 inches thick, which should be composed of equal parts loam, peat, leaf soil, and sharp silver sand. Many of the plants which are to go into the soil are really peat-loving, therefore it is necessary that peat be used; while some of the kinds would do equally well without, still none object to this mixture. Make the soil quite firm, that it be not of a spongy nature, as much depends upon the firm manner in which the cuttings are inserted. If the soil be moist, as it should be when used, no difficulty will be experienced. Over the soil place half an inch thickness of coarse silver sand, as when the holes are made for the cuttings some of the sand is carried down to the bottom of the hole with the dibber. Water the soil with a fine-rose waterpot, when all will be ready for the cuttings. This preparation should be made before the cuttings are obtained, as no delay in inserting them must occur after they are severed from the parent plants.

According to my experience the best time to take the cuttings is during the early part of September, when the current season's growth will be partly ripened, sufficiently so to make callusing an easier matter than if the insertion of the cuttings be delayed until the following month. Where it is possible the cuttings should be pulled or slipped off, retaining a small portion of older wood, which is more suitable for forming roots than the parts only of the current year's growth. Particularly does this apply to Conifers. The length of the cuttings must be determined by the plant under consideration, as, for instance, *Retinospora plumosa* may be 2 inches long, and *Thuopsis* will need to be at least 4 inches long to obtain the necessary cut at the base containing a small portion of firm wood. Select the cuttings in the manner described, cut square across below a joint, trimming off the lower branches or feather as far as is required for the cutting to go into the soil. Fix them firmly at the bottom of the hole with the dibber. Fill the holes again with sand and give a gentle watering to settle the soil about the cuttings. Unless the sun be very powerful after this time no more water will be required until the spring beyond a light sprinkling should the surface become dry, which will depend upon the state of the weather. For a time shade the cuttings during the hottest part of the day. Ventilation will not be required except a little now and then to evaporate moisture, which will otherwise cause the cuttings to suffer. During the winter protect the sides of the frame with manure or leaves to prevent the soil in the frame being frozen too hard, as this has the effect of loosening the soil about the cuttings when it thaws, and then roots are not so quickly formed. Double mats thrown over the frame in severe weather will be beneficial in this respect.

In the spring, when it is seen that new growth is being formed, air should be admitted freely to keep the plants stocky, as much depends on this for their future welfare in forming shapely bushes. A western aspect for the frame answers well, perhaps better than a southern position, for the reason that if some of the cuttings do not root so readily as others, the powerful sun sometimes experienced during April and May will dry them too much. As before stated, some kinds root more quickly than others, and are ready to be removed from the frame during the early part of the following June, and be planted either in their permanent quarters or be transferred to a nursery bed for a season. When removal from the frame takes place the advantage of a layer of manure or leaf soil will be seen in the manner the roots cling to it, rendering

the process much easier and safer to the plants. The position for the plants the first year may either be on an east or west border, or any open space may be selected, planting either in nursery beds or in rows 9 inches apart, adding to each a portion of leaf soil if the natural soil be of a heavy nature, otherwise the addition of leaf soil will not be necessary. Should the summer be hot a mulching of partly decayed leaves between the rows will be of great advantage in keeping the roots cool and moist. I purpose naming those kinds which root the most readily and need to be planted the first June after the cuttings were taken, as such sorts may go in at one time, thus simplifying the matter of planting and frame room later on. The others, which require more time to make roots, should remain in the cutting bed for a year, when they could safely be planted out the following April. During the summer and autumn take the lights off when it is seen that all that are going to thrive have formed roots, as some varieties after taking six months to callus require a still longer period after that to make roots freely. The advantage of using two frames instead of one is now obvious.

First list for early planting.—*Retinospora plumosa*, *Cryptomeria elegans*, *Thuia borealis*, *Thuia Lobbi*, *Cupressus erecta viridis*, *Golden Yews*, *Thuia occidentalis*, *Escallonia macrantha* and a small flowered pale pink variety with small leaves flowering in July, *Veronica Andersoni*, *Laurustinus*, *Fabiana imbricata*, *Garrya elliptica*, *Buddleia globosa*, *Cotoneaster Simmonsii*, *Kerria japonica*, *Lonicera reticulata aurea*, *Ampelopsis Veitchii*, *A. hederacea*.

Those which require a longer time to form roots.—*Wellingtonia gigantea*, *Cupressus macrocarpa*, *C. gracilis*, *C. Lawsoniana*, *Thuia Wareana*, *Retinospora plumosa aurea*, *Euonymus japonica aurea variegata*, *Lonicera fragrantissima*, *Ceanothus azureus*, *Jasminum nudiflorum*, *Pyracantha*, and *Myrtles*.

Aucuba japonica is one of the most useful evergreen shrubs we have. It is best propagated in this manner. At the end of September take the cuttings, 4 inches long; moderately strong side shoots are best, retaining a small heel. Insert them firmly in sandy soil about eight or ten in a 7-inch pot. Water gently to settle the soil firm about the cuttings. Plunge the pots in ashes in a cold frame. Little air will be required in the winter during the time they are callusing. About the middle of March plunge the pots in a gentle bottom heat, where roots will quickly form, when the plants should be hardened and planted out the following early part of June along with the rest, where they should stay the first year, and will then be ready for their permanent quarters.

The best of Laurels are the Caucasian, *rotundifolius*, common, *colchicus*, and the Portugal Laurel. The second named is the best for banks where a dense low growth is required or for forming hedges, being short-jointed and of a free habit of growth. If manure be added to the soil at planting time the colour of the leaves is much improved, as in poor soils they have a tendency to remain pale green, which deteriorates somewhat from its appearance, in the winter especially. Behind a north wall is the best position to root Laurels. Early in October the cuttings about 6 inches long should be slipped off, preferring medium sized shoots to large sappy growths. Chop out a trench with a spade about 3 inches deep, placing a layer of sand at the bottom, the cuttings being inserted about 4 inches apart. Fill in the soil, treading it firmly about the cuttings, digging the ground as the work proceeds, when the next row should be 10 inches from the first. The chief point is to thoroughly secure the cuttings in the soil, as if they are left loose roots cannot form. Previous to sharp frosts being expected it is wise to mulch between the rows with partly decayed leaves, as this prevents the ground becoming frozen hard, which when a thaw sets in renders the cuttings quite loose in the ground. After frost tread the soil about the cuttings firmly. For one season let the plants remain in their present position, when they may be transplanted, allowing more space to each. Irish Ivy, the best of all the Ivies for general use, may be propagated precisely in the same manner as Laurels, with the single exception that the cuttings may be cut into lengths of 8 inches, selecting the current year's growth and without the heel as advised for the Laurels.—S.

SOME CONSPICUOUS CATERPILLARS OF 1888.

As, from various causes, the present summer has been somewhat scant of Court and political news, the advent of a "plague of caterpillars" has been quite a godsend to sundry periodicals of the day, enabling them to anticipate the "big Gooseberry" season. According to the usual course of things some nonsense has been written on the subject by journalists deeply ignorant of entomology, and with no great knowledge of horticulture. We have not yet had reports sufficiently full and exact from the different counties to enable us to ascertain all the facts, but it would appear that rumour has exaggerated the mischief done as yet. Some of

the caterpillars referred to are evidently species that are usually common, but in the general way their proceedings are not remarked upon by the Press. Other species have, no doubt, been exceptionally abundant, perhaps more in south Britain than in the north. One circumstance is notable, that our entomological magazines during the winter published statements concerning the scarcity of *Lepidoptera*—i.e., of butterflies and moths, in 1887, presumably through the dry season. As the hosts of caterpillars observed in many places this spring and summer must have had parents we must assume that moths at least must have been more plentiful (if unnoticed) than was thought; and we also infer that the cold of last winter and spring was not, on the whole, prejudicial to such *Lepidoptera* as pass through those seasons in the egg state or as hibernating larvæ; the latter are often destroyed by a continuance of rain. Another fact is to be borne in mind, that the considerable amount of rain which has fallen in many English counties during June and July (in some cases during May also) must have helped to reduce materially the number of caterpillars.

The caterpillars now to be mentioned have been nearly all under my own observation in districts of Kent and Surrey within about thirty miles of the metropolis; other places may probably have suffered more from these insects, and some less. To begin with, a woodland moth, the little green species called *Tortrix viridana*, has been particularly abundant in woods, copses, and shrubberies. Wherever Oak was to be found it has been infested by the caterpillar, a small creature, but able to do much damage; like the moth it is bright green. Occasionally we find it driven by shortness of food to eat Hazel or Hornbeam, but its preference is for Oak. Showers of the moths flit amongst the boughs in June and July, succeeding to the caterpillar brood of May. These moths, it is noticeable, are hunted and eaten by several small birds, and they fall a prey also to a fierce ichneumon fly of the genus *Empes*, to which they can make no resistance. Every year we scarcely ever fail to see, in variable numbers, the small ermine moth (*Yponomeuta padella*) disfiguring our Hawthorn hedges. Occasionally, as in 1888, the species makes an attack upon fruit trees. It would appear that it is this insect which, in its larval stage, has been chiefly the cause of the damage sustained by the Apple in our Kentish orchards, the too sociable black-spotted caterpillars spreading their webs over twigs and branches, whence they came forth in their companies of hundreds and thousands, and in many cases the trees were nearly denuded before any steps were taken to clear webs and caterpillars. It is not at all difficult to shake off the caterpillars and destroy them, specially when they are young. Afterwards the best thing to be done is to remove, and then burn, all the webs, in which the cocoons are generally hidden.

Perhaps of the caterpillars that are common this season the public have seen most of the species oddly known as the lackey, or *Bombyx neustria*. It is a frequent thing for them to descend from trees and shrubs upon by-passers, and many are to be seen racing along paths, for they are easily dislodged from their resting places as they get larger; while young they hold on firmly, because they run united by lines of silk along the boughs where they are feeding. The caterpillars have fed this summer upon an extensive variety of trees and plants, sometimes abounding in orchards. They are easily recognisable by the two black spots on the grey head, which look like eyes, but are not eyes, though these organs exist as in other caterpillars; the body is striped with white, blue, orange, and black. Each mother insect places her eggs in a compact ring round some twig, where they are left to hatch in spring, but they should be sought out and removed. Another caterpillar which has been specially numerous is that of the mottled umber (*Hybernia defoliaria*), appearing in orchards, gardens, and the open country. This is a beautiful caterpillar of the geometer or looper kind, not naturally gregarious, though they often seem to be feeding in companies, as they seek out the young and juicy leaves, travelling over many shrubs and trees, but being partial to those of the Rosaceous or Prunaceous orders. Each travels about provided with a coil of silk, by which it can drop a long or short distance and again ascend to its food. It is a caterpillar of conspicuous colouring, and it may possibly escape bird foes by this contrivance. The moth is one of those that emerge during the dull or stormy weeks at the end of autumn. The females are wingless; hence, as after pupation they emerge from the earth, it has been advised to smear some sticky composition round the stems or trunks, over which the insects cannot crawl to deposit eggs. This plan has been very successful in checking the increase of the winter moth (*Cheimatobia brumata*), the whitish green caterpillar of which is so mischievous to Plums, Pears, to our mixed hedges in some years, and to other fruit trees occasionally, each individual hiding in a web. This species, however, has not, so far as I know, been particularly complained of in 1888, having been eclipsed by the little ermine already noticed.

The caterpillars of the gold-tail moth (*Liparis auriflua*) are stated to have been very common in some southern counties, but about Kent and Surrey there has been a rather less number than usual. It is an insect seldom seen in gardens, preferring vegetation along the lanes and borders of woods. Some of the journals which have referred to the "caterpillar plague" have stated that the insects have sometimes caused a peculiar eruption, or "caterpillar rash," in the human skin. This is known to occur in the case of certain hairy caterpillars, as with the above "gold-tail," and its near relative, the "brown-tail," where they are plentiful. This latter (*L. chrysorrhæa*) according to reports which bear the stamp of authenticity, was, many years ago, a serious enemy to our fruit crops. Of late it has been comparatively scarce, and occurs only upon the Sloe and Whitethorn. It would be a noteworthy fact should its caterpillar have appeared this season on any fruit trees, and I should be glad to receive, through the Editor of this Journal, any account of its being detected. I may state that the caterpillar is black, striped with vermilion, and has along the back tufts of white bristly hairs; upon the fifth segment from the head there is a double hump.

The hairs of the caterpillar of the great tiger moth (*Arctia caja*) have an irritating effect upon some persons, young and old, possibly all the "tigers" may. It is a species which sometimes finds its way into our gardens, eating Mint, Lettuce, and other vegetables, and is a hearty feeder. Its numbers this season are probably above the average. A moth that has been abundant in June and July is that named the silver Y (*Plusia gamma*), flying about day and night, and therefore we may expect the caterpillars will be out in force later on during August and September. Their food is so varied that they do us little harm, but in France they prove very destructive to pot-herbs.—ENTOMOLOGIST.

NOTES ON STRAWBERRIES.

LAYERING.

THERE are various methods of obtaining an early stock of well-rooted runners, all of which answer if properly carried out. One of the simplest is to take a number of the strongest before they have been trampled on and lost the first-formed roots. These being dibbled in a bed of fine light soil and covered with shallow frames soon become well rooted, and can be transplanted to their final quarters early. If only a few dozens are wanted they may be dibbled into boxes and placed in frames, or a few handlights may be filled with them. When the runners are transplanted, either from frames, boxes, or even from between the rows of old Strawberry plants, they invariably take more quickly to their fresh quarters than do root-bound plants turned out of small pots. In showery weather the runners soon strike root into ridges of fine soil placed midway between the old rows, or they may be pegged to squares of turf. Perhaps the majority of the plants are layered into small pots at the same time as others are prepared for shifting into the larger pots in which they are to fruit. If taken early, the best only being selected, and either pegged down or fastened with pebbles to the firmly packed soil in the pots, and kept well supplied with water, they soon fill the pots with roots. The final planting should be done as early in August as possible.

PREPARING GROUND.

Strawberry plants are seldom profitable after producing four crops, and in some instances they last in good bearing order an even shorter time. The first crop is the earliest, the fruit also being fine; the second is usually the most valuable; the third, perhaps, the heaviest, the fruit, however, not being of great size, while the older plants produce abundance of fruit for preserving. The oldest bed, therefore, should be destroyed every year, and a new one planted, and in this manner and by varying the sites a good supply of fruit is annually produced, if not always ripened satisfactorily. It is a crop that usually pays for trenching the ground, but it must be remembered that a loose, rich, and deep root run encourages the formation of much foliage, and to secure the required abundance of fruit the ground must be made very firm. The best plan is to well manure and trench the ground during the winter, cropping it in due course with Ashleaf or other early maturing Potatoes. This allows good time for the ground to settle, and the Potatoes being cleared off early, all that is further necessary, to clear, level, and trample the surface prior to putting out the plants. If the trenching, or rather double digging—as it is unwise in most instances to bring the subsoil to the surface—has to be done now, after the rough manure has been forked into the bottom spit, this should be heavily trampled, the top spit also given a dressing of more decayed manure, being similarly treated. Any ground now waiting for Strawberries should have all rough lumps broken down before hot or dry weather

bakes them, and the surface being thus kept fine and moist, the planting may be done in the driest weather.—W. I.

PEA GRADUS.

THE new early Pea Gradus was raised from Telephone × Wm. Hurst, and the produce of intercrossing these two Peas, as might be anticipated from the position they have secured, has been particularly fertile in producing good progeny, both tall, intermedial, and dwarf varieties, and amongst a numerous offspring Gradus is pre-eminent for its earliness, large pod, and productiveness as a variety of intermediate height. Gradus was sown at Girtford this year on the 11th April in an open position and ripened the second week in July with a good stock of

FIG. 7.—PEA GRADUS.

William I. sown in a sheltered position on the 23rd January. The pod being large and well filled, and being a bluish-white wrinkled variety, Gradus must be an important advance in many respects. The height of the new variety does not much exceed that of Earliest of All. I believe the stock of Gradus to be fixed as well as it is possible to fix a Pea raised from cross-fertilisation, the variety having been carefully selected for several seasons.—T. LANTON.

FONTHILL ABBEY, TISBURY.

THE manor of Fonthill (so called probably from the abundance of springs that gush from the sides of its hills) is situate in the hundred of Dunworth, about sixteen miles west of Salisbury and two from Tisbury Station on the South-Western main line of railway from London to Exeter. In "Domesday Book" it is described as part of the

possessions of Bereger Giff, in whose family it continued until the time of King John. Frequent vicissitudes (as recorded in "Michael's Important Spots in Wiltshire") attended Fonthill during the interval from the Norman Conquest to 1800, and at the end of the year 1825 the magnificent structure known as Fonthill Abbey became a ruin. A square tower and adjoining hall, together with a large square of green swarth having raised banks sloping inwards, are now all that remains to mark the site of this fair creation. The Fonthill estate was soon after disposed of by auction to the late Marquis of Westminster, by whom, with the assistance of Mr. Burn, the present commodious and picturesque Elizabethan mansion was erected. It is now the Wiltshire residence of Sir Michael Shaw Stewart, Bart., and, owing to the high position on which it stands, commands a fine and varied prospect of Wilts and Dorset scenery, and is approached by three fine lodges (Tisbury, West Gate, and Stone Gate), and broad and well-kept carriage drives, which, winding o'er hill and dale, disclose not a few pleasant peeps of home and distant scenery, including the undulating Pine woods of Wardour Castle with the lofty steeple of Salisbury Cathedral in the background.

Approaching the abbey from the Tisbury entrance many fine specimens of choice trees and shrubs are passed. Of the former the most notable are the Silver Fir. Many of these 3 feet from the ground are 12 feet in circumference, 100 feet high, and as straight as a gun barrel. One, having a trunk 15 feet round, is a most remarkable specimen from the fact of its having eight stems of uniform growth, and about 100 feet emanating from it in the shape of an eight-pronged fork at 8 feet from the ground. There are also several specimens of *Wellingtonia gigantea*, about 50 feet high, and clothed from base to summit with luxuriant foliage. Choice *Rhododendrons*, *Kalmias*, *Berberis Darwini*, &c., are well represented on the sloping banks and in clumps at the north front of the abbey.

The flower garden, which is immediately opposite the south front of the abbey and contiguous to the ornamental grounds, is sunk and enclosed by terraces and ornamental balustrading, on which a variety of statues representing various deities are interspersed. It is geometrically laid out, and the beds being well filled with a variety of foliage and flowering plants judiciously arranged as regards colour, had, when viewed in connection with the surrounding landscape, a very pleasing and telling effect. Proceeding a short distance westward from the abbey we suddenly come upon the American garden, which for beauty of situation and formation of surface, luxuriant trees and shrubs, is probably unmatched in England.

In the deep winding valley is a succession of irregularly formed miniature lakes, having small islands surrounded by massive pieces of rock and covered by choice trees, shrubs, and trailing plants situate on different levels; the lower lakes being fed by the upper ones, thus forming a series of cascades, which, "foaming down the shaggy rocks," are very effective. There is a profusion of Water Lilies, and snow-white swans which float majestically on the dark waters of the several lakes, which at their narrowest points are spanned by rustic bridges draped with Honeysuckles. Fine specimens of Portugal Laurels, Azaleas, *Rhododendrons*, *Kalmias*, and other species, in variety, of American plants, together with groups and specimens of *Deciduous Cypress* (*Taxodium distichum*) and kindred species, clothe the adjoining slopes from base to summit. To the right of the point at which we entered this romantic and beautiful retreat huge stone steps lead up a steep ridge through grottoes, wilds of Fern, and under the shade of huge *Rhododendrons* and gigantic Firs to the site of the old abbey referred to above, the walls of which are draped with *Pyracantha*. In front, on the beautiful turf, are two circular stone vases 7 feet across, and one basket-shaped one 15 feet long, and which were at the time of my visit filled with a variety of flowering plants, including some of trailing habit, which, hanging gracefully over the edge of the vases, gave finish to the arrangement. From this coign of vantage is seen a fine green glade westward, nearly a mile in length, and which had formed the chief entrance to the abbey. We may here remark that the keep of the extensive woods, the well-made broad carriage drives—drives which to our mind invariably invest the destination of the visitor with a sense of liberality and importance—reflect great credit on Mr. West, the able forester on the Fonthill Abbey estate.

The kitchen garden is enclosed and divided in two portions by high brick walls. It is situate on the face of the hill about a quarter of a mile east of the abbey, and having a south aspect. The soil being a stiff loam resting on a bed of clay is not only congenial to the growth of vegetables, of which there is a good supply, but also to that of fruit trees, especially during a season like the one through which we have just passed, as testified by the fine examples of Pear and Plum trees which embellish the walls, and the fine pyramidally trained specimens of the former on each side the central walk. These trees, together with the sundry improvements which had been carried out in the gardens and grounds during the interval from the year 1865 to 1881, also testify to the skill and ability of the late gardener, Mr. Annandale.

The glass houses, the most notable of which is a curvilinear-roofed Peach house, 100 feet long, 8 feet wide, and 13 feet high at the back. The condition of the Peach trees *Royal George*, *Noblesse*, *Violette Hative*, and *Imperatrice Nectarine*, which occupy the back wall, and from which the crop had been gathered, augured well for next season. At the north side of, and communicating with the kitchen, are located a span-roofed house, pits, and frames, and good shedding accommodation. Provision in the way of an enclosed space is also made here for the erection of a good block of houses and pits. The front of the Peach

house indicated is a capital place for the growth of Tomatoes from the time the fruit have set in March or April until late autumn. The plants should be trained under the roof to a trellis fixed thereto, at about 9 inches from the glass to the height of 5 feet, and at intervals of 10 or 15 feet, so as not to exclude too much light from the trees on the walls. In this position the shoots and leaves should be kept well stopped and thinned to prevent crowding of either shoots or leaves from taking place, as this would spoil the chance of securing satisfactory results. And with this object in view the plants should be kept liberally supplied with weak liquid manure at the roots while swelling their crops. The condition of the gardens generally do Mr. John Macey, the head gardener, much credit.—W. H. W.

ROSES IN WINTER.

THE three questions submitted for my opinion on page 30 scarcely present themselves as the composition of a "learner" whose inability to fill in my "sketch" is the apology for their introduction. The first question would in all probability have formed the subject of my next paper. The carefully worded letter on page 30 is too guarded to be the outcome of a "learner," and touches in the first question the most perplexing and most difficult matter that the grower of Roses for winter has to contend with. Success in no small degree depends upon the manner the plants are rested, and the period they can enjoy complete repose before an attempt is made to start them into growth.

The second question embodies a doubt while soliciting information. The nature of the soil for potting as well as the border, if the Roses are planted out, would perhaps have been better dealt with at the beginning, but I did not intend to leave them for the "learner" to "fill in" unless the Editor hinted I had better draw the subject to a close. The third question has been practically answered, and would not have been further reviewed because much can be said on both sides of the question. But I will touch upon it again, as I am desired to do, as well as the other two, and in the order in which they are named.

The first question then is, "How Tea Roses are to be kept at rest" during September and October when planted out in a house with the roof lights removed? for the rain would fall on them and mild growing weather affect them as if quite in the open, where Tea Roses grow and flower freely then." The context to the question at first sight presents a difficulty. There is, I admit, and as I have previously stated, a great difficulty in keeping Tea Roses from growing during late summer and early autumn, but much depends upon the method of culture during the earlier part of the season—say, from May onwards. If kept under glass the whole season will they not persist in growing as freely during August, September, and perhaps October as they would, if fully exposed to natural conditions—that is, the lights removed and the plants subjected to the weather, even supposing it to be mild and showery? They will, unless extremely unnatural measures are practised, to prevent it. When confined under glass how can growth be prevented, except by severely drying the soil about their roots? No half measures will accomplish this end; the soil must be kept so dry that growth is impossible, and this unnatural method of culture is decidedly injurious. I am no advocate for forcing rest upon the plants by methods that should be obsolete. Such practices impair the constitution of the plants, and enfeeble them to such a degree that they are fit subjects for an attack of any disease. What is the result, but puny growth, small flowers, and short life, instead of good health to enable the plants to resist disease and long life?

Rest in autumn is influenced in no small degree by the time the plants flower at first and their after treatment. Suppose the plants commence flowering in February, they will continue doing so more or less until May, being only a slight break, if any, with a good stock of well established plants. I am now writing of such varieties as *Niphetos*, which, as far as growth is concerned, may be taken as the type of many others. The first flowers will be from the ripened wood of the previous season, while the succeeding ones, which are often the best, come from the base and back breaks, and thus keep up the supply. The plants would, if allowed to do so, flower again profusely during July, and again in September and October. Supposing they commenced flowering in January they would flower for the last time a month earlier. But if the flowers are removed as they appear from the time indoor Roses are practically valueless, time is gained, and growth should be completed fully a month earlier. But "S. S." may say, What advantage is gained if the plants will persist in growing? Why this, if they are well cared for and assisted to make and complete a good growth, the wool necessary to be retained will be hard and well ripened, and the soft twiggy growth at the extremity of the shoots (unripe ends) can be cut away. Under glass rest must be forced upon them by the extreme measures I have pointed out, or they cannot be brought to a complete standstill until they have been subjected to frost. It takes more frost to bring about this condition when they are protected by glass than when they are exposed. Plants that may be flowered during the

months "S. S." has indicated, and then hardened and turned outside will rest for a time, and then commence breaking into growth in September. From plants subjected to this treatment we have been in the habit of obtaining our supply of flowers up to Christmas, but they are practically unfit for early forcing. If the plants are encouraged to make and complete a good growth after they cease flowering in May, before the lights are removed, they will, although they may grow slowly, be thoroughly maturing their wood in a natural manner, and ready to rest by the time the first frost appears. We are just as liable to have early frosts to bring about this end as we are to have moist, mild, genial weather. Whatever the weather may be in the day the nights at that season are often cold, and these, even without frost, have a wonderful effect upon plants that are only struggling to grow.

No comparison can be drawn between Roses that are started into growth to commence flowering in January and those in beds and borders outside that do not commence flowering for five or six months later. These flower, and are then often retarded by drought. Heavy rains in August, or about that time of the year, have a natural tendency to start them again vigorously into growth. The one is ready to rest when favourable circumstances occur, and the other is often rested too soon; and if the weather proves severe we are only too familiar with the consequences at pruning time in spring. Once the plants are brought to "rest" there is no difficulty in keeping them in that condition as long as may be desired. Exposing the plants to frost is the surest method of inducing rest and securing strong breaks afterwards. Lift Rhubarb after the leaves have faded, and expose it to one good frost, and it can be forced as freely as if it has been resting for two months; and the same applies to Roses that have been assisted to make their growth early under glass. The latter after they commence growth are influenced much by the weather. Turn a number of Roses outside after growth has been completed of Gloire de Dijon, Maréchal Niel, or any kind, and subject them to frost, while a like number in the same condition of growth at the time are kept under glass, and see which will force best and earliest early in the season.

The second question is, "What is the composition, nature, texture, and composition of the soil or compost to be used for such large pots and such young plants?" This plainly embodies a doubt that the pots I have recommended to be used are too large for such young plants. "S. S." would consider a 10 or 12-inch pot too large for the young Vine placed into it out of a 6-inch pot in May. The pot certainly looks large for the small weak plant, probably only 18 inches high and half the thickness of the pencil with which I am writing, but, is it too large at the end of the season, when by good culture it has developed into a strong cane? But I need not wander from the Rose for examples. Is not Maréchal Niel, Gloire de Dijon, and others that are worked or rooted early in the year, and attain a length of from 15 to 25 feet or more, plants large enough to be a credit to the grower without condemning or casting a doubt upon the practice that has produced them, even though they have been placed in June or July into 10-inch pots? I have grown Gloire de Dijon the first length indicated and much branched; Maréchal Niel with shoots over 25 feet from cuttings rooted in February, potted, and finally placed in 10-inch pots in July. If such success can be achieved with strong growers such as these, corresponding results can be attained with Niphetos and the smaller growing varieties. But Niphetos is not the poor weak grower that it is often thought to be if repotted from the time it is first worked and grown on without a check with liberal root room. It is a small puny grower when checked in its early stages by being too limited at its roots. Early worked plants, if well cared for, should be strong, 18 inches high with three or four shoots early in May, and well established in 5-inch pots. If placed into 7-inch pots without checking them, what shift will they require in July? The largest 10-inch pots and the smallest 9-inch. The pots look large for the plants at first I admit, the same as they do for Vines, Gloire de Dijon, or Maréchal Niel, but what opinion would be passed upon them at the end of the growing season? Compare this, then, with what I have written, and I think "S. S." will have still graver doubts about the pots, and perhaps the size of the plants as well.

Having dealt so far with the size of the pots, I may turn my attention to the soil I consider suitable. I prefer two-thirds fibry loam, intermediate between light and heavy, and one-third leaf mould, passed through a half-inch sieve. To this add one-seventh of decayed manure and sufficient coarse sand to render the whole porous. A 6-inch potful of soot, and the same quantity of quarter-inch bones with the fine left in may also with advantage be added. If the loam is of a light nature I should dry some clay and reduce it to powder, and add about one-seventh, and dispense with the sand. If heavy a greater percentage of sand or any gritty material would be used, charcoal being useful for the purpose, charred soil, bricks broken fine, or even old lime rubbish to lighten and keep it open. These should be used in quantity according to the texture of the loam. Even with loam of an intermediate nature a little of the latter will do no harm. The manure may also be varied according to the texture of the loam. If light I should use cow manure if I could get it, and horse droppings merely sweetened and passed through a half-inch sieve if heavy. In future pottings—that is, during the second and third year, or as long as the plants are kept in pots and subject to repotting annually, I advise a little richer and less light compost to be used. The quantity of leaf soil would be less, as well as the sand, while the manure would be slightly increased. The pots should be carefully and liberally drained and the soil pressed into them moderately firm. The soil would be pressed firmer in the pots at any repotting needed after the first year.

I have previously commented to some extent on the border and its preparation; I have alluded to the drainage, whether the border should be above the ground level or the reverse, and also whether the natural soil should be removed and replaced with fresh. If the natural soil was good and the subsoil of such a nature to insure thorough drainage I should not remove it, or at least only a portion, so that the beds would not be too full by the addition of the ingredients added to it. If the natural soil would grow H.P.'s well it would be a waste of labour to remove it. All that is needed is to lighten it by the addition of the materials I have advised for that purpose when the plants are grown in pots. If too light clay in the manner I have described would be added. Under any circumstances I do not advise the use of leaf mould for the border that may have to stand for some years for fear it might be the means of filling the soil with fungus. Tea Roses enjoy a little leaf mould, and grow with luxuriance when it has been added to the soil, but in spite of this I should not run the risk of failure by adding it to the border.

The third question is, "Whether, in growing Roses for cut flowers for market in January, February, and March it would be most profitable to plant out inside beds near the glass or to grow them in pots, taking into account all the labour in the latter method?" This contains the substance of what would make a long article if I had to give all that can be urged for the one system or the other in deciding this matter. When Roses are forced in pots even for the supply of flowers during the three first months of the year, they cannot be turned out, but must have the protection of glass for nearly three months longer. Even supposing they could be turned out of the house in which they were forced, the protection of glass would have to be accorded them for some considerable time, and this amounts to the same thing in the end. If we suppose they could be turned out at the end of March I do not think such a course would be advisable, because plants that flower during those months would flower again profusely in May or just preceding outdoor Roses, and then they would be almost as valuable as what they would earlier in the year. The blooms might not be so large, but they would invariably find a ready sale. This year Roses were very scarce for a few weeks before outdoor ones came in, and buyers would have been glad of the small buds of Safrano and Isabella Sprunt that they would have despised a month earlier. I certainly advise planting them out in preference to keeping them in pots, and although they might take up the house the whole of the season the better blooms they would produce, and the greater quantity they would yield, would render them more remunerative than if they were grown in pots, so that they could be turned out when the weather was sufficiently genial, and the house occupied with other plants. One of the reasons why I advised the use of moveable lights was because, when growing for the market, it is necessary in these days of keen competition and low prices to make the most of things. The lights could be utilised for the culture of other things when the Roses did not need them. If unnecessary to keep Roses in pots under glass the whole of the season, why is it necessary to keep those that are planted out? As far as my experience goes, for the sake of a little extra cost in construction, a certain amount of glass is practically idle when it might be utilised for the culture of other plants.

A grower who had large quantities of Niphetos and other varieties in pots for yielding flowers for the market was advised by a friend and myself to plant them out. For this purpose he erected a span-roofed house, 80 or 90 feet long and 20 feet wide for them, and is thoroughly satisfied with the results. I should not advise the erection of houses for Roses with only side beds, I prefer a bed in the middle as well as on the sides. But if I had houses of this description I should not hesitate planting the Roses out in preference to keeping them in pots.—WM. BARDNEY.

ROSES AT BIRMINGHAM.

A CORRESPONDENT sends the following note respecting the Exhibition recently held in Birmingham. "It was an excellent show. Mr. T. B. Hall and Mr. Grant said that the quality of the Roses was far ahead of the Crystal Palace National Show. Mr. Grant showed in very fine form, also Mr. Hall, Paul & Son, and Messrs. Jefferies & Son of Cirencester, showed very well indeed. Of course the feature of the general, or as the French say, the "tout ensemble," of the Show centred itself on the Delphiniums exhibited from Alderminster. One nurseryman had the impudence to put in no less than three Marie Baumanus in a stand of twenty-four. One named correctly, the other two sweet "Maries" being named respectively Duchess of Bedford and Mrs. Harry Turner. This box of twenty-four was thrown out, not because of the duplicates or triplicates, but because of its manifest inferiority. It was only after the judging that attention was called to the subject."

ELTHAM.

IN this uncertain and disappointing season it was something for the promoters of this Show to have secured a fine morning, and the grounds of Eltham Court, the residence of Mr. Bloxam, in which the Show was held, looked very pleasant in the bright sunshine, although threatening clouds seemed to portend already the rain, which was so universal. On the following day, Sunday, however, the most was made of the glimpse of fine weather, and while here, as elsewhere, lamentations were many and great over the failure of fondly cherished hopes, yet a good show was held, small in extent, but with some fine flowers exhibited.

The Eltham Show is a small one at the best of times, and although it offers open prizes which have frequently brought some of our large nurserymen from a distance, yet the fixture of Manchester on the same

day prevented many from coming, while the absence of Mrs. Fuller, in the amateurs' classes, deprived it of the very fine stands which she is in the habit of exhibiting. The decorations and the exhibits of cottagers' produce combined to make a pretty and interesting show.

In the open classes for twenty-four varieties Mr. R. E. West of Reigate was first with François Michelin, Le Havre, Alfred Colomb, Etienne Levet, Marguerite Brassac, Marie Baumann, Marie Finger, U. Brunner, Duke of Edinburgh, Madame Eugène Verdier, A. K. Williams, Captain Christy, Annie Wood, La France, Baronne Adolphe de Rothschild, Dr. Andry, Duke of Teck, Pierre Notting, a flower now seldom seen, and discarded by most on account of its difficulty in opening; Mrs. George Dickson, Prince Arthur, Comtesse d'Oxford, Louis Van Houtte, and Baroness Rothschild. Mr. West was also first in twelves with François Michelin, Baroness Rothschild, Etienne Levet, Marie Finger, Duke of Edinburgh, Alfred Colomb, Charles Lefebvre, Marie Baumann, Captain Christy, Dr. Andry, Madame Victor Verdier, and Ulrich Brunner. In the class for twelve Teas the first prize was awarded to Mr. Burnand, another Reigate grower, who has recently entered the field, and whose success will, we may hope, lead him to greater efforts. His box contained good blooms of Madame Lambard, Innocente Pirola, Souvenir d'un Ami, Rubens, Isabella Sprunt, Andromede, two Roses which one very seldom sees now; Letty Coles, Prince of Wales, Amazone, Caroline Kuster, Jules Finger, Marie Van Houtte.

In the class for amateurs, eighteen single varieties, the first prize was awarded for a box containing Duke of Edinburgh, Madame Montet, Eugène Verdier, Marie Baumann, Madame Hippolyte Jamain, A. K. Williams, E. Y. Teas, Merveille de Lyon, Madame Thérèse Levet, Fisher Holmes, Villaret de Joyeuse, Charles Lefebvre, Marie Verdier, Sir Garnet Wolseley, Madame Charles, Ulrich Brunner, and John Hopper. In the class for twelve the first prize was gained for a capital stand of flowers, consisting of Etienne Levet, Duke of Edinburgh, Fisher Holmes, Villaret de Joyeuse, A. K. Williams, Baroness Rothschild, François Michelin, Madame Hippolyte Jamain, Madame Montet, Madame Isaac Pereire, and Abel Grand.

These were the principal classes. I cannot, however, pass by without mentioning it, the very beautiful table and other decorations which were exhibited. Some were exceedingly tasteful and elegant in design, and I think the basket of Roses contributed by Miss Bloxam was the prettiest I have ever seen, and I have seen a good many. I have always held that there are few flowers more difficult to arrange than the Rose, and that most of those arrangements which I have seen are lumpy and inelegant, but this was delightful. It was composed almost entirely of three kinds—Mdlle. Eugénie Verdier, Princess Louise Victoria, and a climbing Rose called Alice Grey, not often seen; the flowers in all cases were small, and the buds were about half open. There was a little dark foliage interspersed, but very little, and the whole effect was elegant in the extreme. One of the table decorations which mainly depended on the three varieties of *Papaver nudicaule* was also remarkably good.

CHRISTLETON.

THE beautiful grounds of Christleton Rectory did not show to advantage on the dreary morning of Monday, the 16th July, when the annual Show was held. This was to be deplored, not merely for the sake of the exhibitors whose energies it considerably taxed to cut Roses after such a day as Cheshire experienced on the previous day, when it hardly ceased raining for twenty-four hours, but because the day is the fête day of the village, in which all take an interest. However, the rain ceased in the afternoon, so that the gloomy anticipations of the morning were not quite fulfilled. Still it entailed much disappointment and considerable loss to the promoters of the Show.

The Show was held as usual in a tent in the Rectory field. There was an excellent display of Roses despite all adverse circumstances; it also contained a most admirable exhibition of hardy herbaceous flowers. The Rev. Lionel Garnet and his brothers are keen and successful cultivators of herbaceous plants, and the stands exhibited, despite the bad weather, were of excellent quality, well grown, clean, and beautiful. A very large number of those who attended the Show were attracted by these collections. Many note books were in requisition, and let us hope will be used afterwards in giving orders; but one is painfully conscious in how many cases this is a mere sham, and the fashionable ladies who make them would begrudge a shilling for a Rose plant, though they will give it readily for a Rose bloom, and probably consider the herbaceous plants as nothing but weeds.

In the class for nurserymen, thirty-six blooms, there were Messrs. Harkness & Sons, Bedale, and Messrs. Dickson (Limited) Chester, who occupied places in the order named. Messrs. Harkness's Roses, which were of fine quality and brilliant in colour, comprised Ulrich Brunner, Lady Mary Fitzwilliam, Madame Montet, Heinrich Schultheis, Madame Caroline Kuster, Comtesse Tretiakoff, Merveille de Lyon, Mons. Noman, Souvenir de Gabrielle Drevet, Charles Darwin, La France, Horace Vernet, Rubens (a remarkably fine bloom), A. K. Williams, Alphonse Soupert, Prince Arthur (splendid in colour), Sénateur Vaisse, Maréchal Niel, Duke of Teck, Souvenir de Paul Neyron, Duke of Edinburgh, Souvenir d'un Ami (excellent), Général Jacqueminot, May Quennell, Magna Charta, Innocente Pirola, Etienne Levet, Pride of Waltham, Innocente Pirola, E. Y. Teas, Marie Van Houtte, Marie Baumann, Crown Prince, Madame Lambard, Madame Charles Wood, and Queen of Queens. In the open class for twenty-four blooms the first prize was awarded to T. B. Hall, Esq., Larkwood, Rockferry, for a good box of bloom, consisting of A. K. Williams, Marie Finger, Charles Lefebvre, Ulrich Brunner, Captain Christy, Duke of Edinburgh, Comte de Raimbaud,

Merveille de Lyon, Marie Baumann, François Michelin, Louis Van Houtte, Dr. Andry, La France, Duke of Teck, Etienne Levet, Rosieriste Jacobs, Marie Verdier, Alfred Colomb, William Warden, Prince Camille de Rohan, Général Jacqueminot, Madame Hippolyte Jamain, and Thomas Mills. In the class for twelve trebles the first prize box contained Charles Lefebvre, Captain Christy, Marie Baumann, Madame Hippolyte Jamain, A. K. Williams, Marie Finger, Etienne Levet, Louis Van Houtte, Baroness Rothschild, Duke of Edinburgh. In the class for twelve Roses of one variety (dark), Messrs. Dicksons were first with Alfred Colomb, and Messrs. Harkness second with A. K. Williams; and in twelve light Roses Dicksons were first with Baroness Rothschild.

In the class for twelve there was a very sharp competition, eight boxes being staged, and Colonel Standish Hore of St. Asaph was first with a wonderfully fine box consisting of A. K. Williams, The Bride, Lord Bacon, Madame Caroline Kuster, Duc de Wellington, Marie Van Houtte, Camille Bernardin, Le Havre, Hon. Edith Gifford, Fisher Holmes, and Belle Lyonnaise. Mr. S. J. Charton was second with Dr. Andry, Madame Gabriel Luizet, Ulrich Brunner, Madame Isaac Pereire, Comtesse de Paris, Duke of Teck, Baroness Rothschild, Marie Baumann, Duke of Wellington, Madame Montet, Prince Camille de Rohan, and Merveille de Lyon. In the class for six Col. Hore was again first with a marvellous bloom of Horace Vernet, also A. K. Williams, Dupuy Jamain, Anna Ollivier, Charles Darwin, and Alfred Colomb. Desborough Walford Esq., was second with Madame Isaac Pereire, Captain Christy, A. K. Williams, Louis Van Houtte, Baroness Rothschild, and Ulrich Brunner.

In the class for twelve Teas there was a sharp competition, and a very close run for the gold medal of the National Rose Society, between T. B. Hall Esq. and the Rev. Lionel Garnet, who were ultimately placed in the order named. Mr. Hall's blooms were Grace Darling, Etoile de Lyon, Madame de Watteville, Madame Willermoz, Comtesse de Nadaillac, Souvenir d'un Ami, Marie Van Houtte, Madame Cusin, Souvenir de Paul Neyron, Francisca Kruger, President and Sunset. Mr. Garnet's flowers were Catherine Mermet, Innocente Pirola, Marie Van Houtte, Madame Cusin, Madame Lambard, Caroline Kuster, Francisca Kruger, Souvenir de Paul Neyron, Comtesse Panine, and two others. In the class for six Teas Colonel Standish Hore was first with Francisca Kruger, Madame Cusin, Innocente Pirola, Souvenir d'un Ami. Mr. W. E. Hall was second with Hon. Edith Gifford, W. A. Richardson, Marie Van Houtte, Innocente Pirola, and two others.

One of the great features of the Christleton Show always is the exhibition of herbaceous plants. Both the Rev. L. Garnet and his brother, Mr. W. Garnet of Lancaster, are enthusiastic lovers of this beautiful and interesting class of plants, and have done much to encourage their culture in this neighbourhood. There are three classes devoted to them, one for thirty-six varieties, another for twenty-four, and a third for twelve. These were well contested by the Messrs. Garnet, Miss Hall, and others. The arrangement of the stands was very effective, and contributed much to the general effect of the Show. In order to show what wealth of beauty there was I give here the list of the premier stand in the Exhibition, that contributed by the Rector himself—*Eryngium amethystinum*, *Hemerocallis fulva*, *Galega officinalis*, *Lilium umbellatum*, *Delphinium* seedlings, *Lilium croceum*, *L. pardalinum*, *Malva moschata alba*, *Pentstemon barbatus*, English Iris, *Oenothera Youngi*, *Campanula grandis* (blue), *Chrysanthemum maximum*, *Centaurea macrocephala*, *Alstroemeria chilensis*, *Scabiosa caucasica*, *Gladiolus Colvilli* The Bride, *Erigeron speciosus*, *Helenium Bolanderi*, *Delphinium sinense* (blue), *Gaillardia maxima*, *Phlox Lady Napier*, *Lilium Thunbergianum*, *Aquilegia cœrulea hybrida*, *Lychnis Haageana*, *Bupthalmum salicifolium*, *Centaurea dealbata*, *Jasione perennis*, *Potentilla Phœbus*, *Campanula Hendersoni*, *Papaver nudicaule miniatum*, *Campanula Trachelium fl.-pl.*, *Lilium Thunbergianum citrinum*, *Matricaria inodora fl.-pl.*, *Catananche cœrulea*; and I have only to add that I think it would be a good thing if Rose societies would follow this excellent example. These flowers are always interesting, and they tend to break up the dead level of the Rose boxes, besides giving an interest to many who do not perhaps particularly care for show Roses.

WIRRAL.

IN delightful contrast to the Exhibition of last year, the Show at Birkenhead brought together the largest exhibition that the Society has ever held, and whereas last season there were only a few of the growers for sale present, this year the firms of Cant, Paul, Harkness, Jefferies, Dickson, Cooling, Prince, F. Cant, Burch, and others were well represented, while the leading amateurs, Grant, Hall, Pemberton, Burnside, Page Roberts, &c., came in great force, and not only was there quantity, but also quality; indeed, I am fain to acknowledge, and that after having seen the National Rose Society's Show at Darlington, that in this respect Wirral has come to the front. At none of the shows at which I have been present, and I have been present at most of the important ones—indeed, I may say all, except Manchester and Birmingham—have I seen Roses in such excellent form. Again has it been the case, too, that the amateurs have fairly gone ahead of the nurserymen in this respect, and no finer Roses have been exhibited this season than those contributed by Mr. Grant of Ledbury. His Roses at Gloucester were good, but those exhibited at Birkenhead were better. Especially are his flowers remarkable for their fine form; the centres are so well built up, and there is so much substance in them, that they are sure to hold a prominent place. The Teas, too, were exceptionally fine on this occasion, and when one saw the stand which had gained only a card of commendation, and knew that there were there others better than it, I

could not but think of the Teas of a few years back, when such a stand would have occupied a leading position. The night before had been wet—indeed, I believe, raining all night, and the morning broke with lowering clouds on which no dependance could be placed; however, happily this cleared away, and the day became sunshiny and fine, but not too hot for the Roses, which stood well, and did not open their eyes on the visitors until quite late in the day.

Taking, then, the nurserymen's classes first, there was a very sharp contest in the seventy-twos, the first prize, after a very long examination, being awarded to Mr. B. R. Cant of Colchester for a fine stand of the following flowers—Madame Isaac Pereire, Marguerite de St. Amand, Alfred Colomb, Magna Charta, Gloire de Bourg-la-Reine (very bright), Etienne Levet, Mrs. Charles Wood, Jean Ducher, Madame Prosper Laugier, Merveille de Lyon, Maurice Bernardin, François Michelin, Mrs. Harry Turner, Madame Eugène Verdier, Countess of Rosebery, Marie Finger, Comtesse d'Oxford, Madame Gabriel Luizet, A. K. Williams, Marie Baumann, Ulrich Brunner, La France, Baron Haussman, Pride of Waltham, Duchesse de Morny, Violette Bouyer, Emilie Hausburg, Mr. John Laing (a good Rose), Mrs. Baker, Souvenir d'Elise Vardon, Benoit Comte, Pierre Notting, Her Majesty, Raoul Duval, Marie Baumann, Charles Lefebvre, Catherine Mermet, Le Havre, Lady Mary Fitzwilliam, Madame Victor Verdier, Marguerite de Roman, Duke of Edinburgh, Madame Ducher, Xavier Olibo, Captain Christy, Louis Van Houtte, Marquise de Castellane, Thomas Mills, Madame Cusin, Madame Charles Crapet, Madame de Watteville, Pierre Carnot, Anna Ollivier, Beauty of Waltham, Madame Montet, E. Y. Teas, Madame Lambard, Duc de Wellington, Rubens, Colonel Felix Breton, Triomphe de Rennes, Comte de Paris, Niphetos, Earl of Pembroke, Madame Raoul Chandon, Général Jacqueminot, The Bride, Horace Vernet, Mary Bennett, Le Havre, and Innocente Pirola. Messrs. Paul & Son were second, and Mr. F. Cant third.

In Class 2, for thirty-six trebles, Mr. B. R. Cant was again first with the following: François Michelin, Général Jacqueminot, Madame Eugène Verdier, Marie Baumann, Her Majesty (a fine tri let), Prince Arthur (beautifully coloured), Baroness Rothschild, Ulrich Brunner, Marie Finger, Etienne Levet, La France, Duke of Edinburgh, Pride of Waltham, Beauty of Waltham, Alphonse Soupert, Alfred Colomb, François Michelin, A. K. Williams, Mrs. John Laing, Edouard Herve, Catherine Mermet, Charles Lefebvre, Madame de Watteville, Maurice Bernardin, Marie Verdier, Countess of Rosebery, Violette Bouyer, Duc de Wellington, The Bride, Mrs. Baker (very good), Niphetos, Duchesse de Morny, Souvenir d'Elise Vardon, Madame Charles Crapet, Innocente Pirola, and Le Havre. Mr. Frank Cant was second, and Messrs. Paul and Son third. For thirty-six single blooms Messrs. Keynes, Williams and Co., of Salisbury, were first with fine blooms of Countess of Oxford, Lady Mary Fitzwilliam, Heinrich Schultheis, Madame Charles Wood, Etienne Levet, Francisca Kruger, Alfred Colomb, Her Majesty, Duke of Edinburgh, Merveille de Lyon, Madame de la Place, La France, Camille Bernardin, Baron Gonella, A. K. Williams, Elie Morcl, Marie Baumann, Eugène Verdier, Ulrich Brunner, Souvenir d'Elise Vardon, Alphonse Soupert, Niphetos, Horace Vernet, Marie Verdier, Emilie Fontaine (a good flower), Marie Van Houtte, Beauty of Waltham, Innocente Pirola, Dr. Sewell, Catherine Mermet, Fisher Holmes, Madame de Watteville, Duc de Wellington, Eugène Verdier, Charles Lefebvre, and The Bride. Second, Messrs. Burch of Colchester; third, Messrs. Dickson (Limited) of Chester, and fourth Mr. Geo. Prince, Oxford. In Class 4, for twenty-four, Messrs. Burch were first with Marie Verdier, Exposition de Brie, Anna Ollivier, Etienne Levet, Captain Christy, Comtesse d'Oxford, Etienne Levet, Marie Finger, Duchess of Bedford, Emilie Hausburg, Fisher Holmes, Innocente Pirola, Madame Cusin, Merveille de Lyon, A. K. Williams, Madame Bravy, Horace Vernet, and Ulrich Brunner. Equal second, Mr. Geo. Prince and Messrs. Jefferies & Son; third, Messrs. Dickson. In class 5, for eighteen Teas, Mr. Geo. Prince was first with Niphetos, Comtesse de Nadaillac, Innocente Pirola, Souvenir d'Elise Vardon, Marie Van Houtte, Adam, Madame Cusin, Alba Rosca, Souvenir d'un Ami, Mons. Furtado, Madame Lambard, Caroline Kuster, The Bride, Francisca Kruger, Souvenir de Sarah Prince (very good), Jean Ducher, Hon. Edith Gifford, and Rubens. Mr. F. Cant was second, and Messrs. Paul & Son third. In class 6, for twelve new Roses, Messrs. Paul & Son were first with Madame Bouchardet, Her Majesty, Victor Hugo (a fine Rose), Silver Queen, Mrs. John Laing (good), Madame Joseph Desbois, Earl of Dufferin, Madame Norman Neruda, The Bride, Grand Mogul (a most promising Rose), Madame Thibaut aîné, and Longfellow.

In the amateurs' class for thirty-six blooms the first prize was awarded to Mr. W. J. Grant, who was in fine form. His flowers were Madame Gabriel Luizet, Dr. Andry, Her Majesty, Marie Baumann, François Michelin, Mrs. Charles Wood, Madame Eugène Verdier, Ulrich Brunner, Mdlle. Susan Rodernahia (a fine Rose, notwithstanding its jaw-breaking name), Beauty of Waltham, La France, Etienne Levet, Dupuy Jamain, Madame Sophie Fropot, Marie Finger, Marie Verdier, Marie Van Houtte, Duke of Edinburgh, Duchesse de Morny, A. K. Williams, Baroness Rothschild, Prince Arthur, Princess of Wales, Auguste Rigotard, Mrs. John Laing, Duchess of Bedford, Souvenir d'un Ami, Comte Raimbaud, Marquise de Castellane, Louis Van Houtte, Rubens (seedling, a promising dark flower), Merveille de Lyon, Jean Soupert, and Le Havre. The Rev. J. H. Pemberton was second, and Mr. T. B. Hall third.

In class 8, for twenty-four, Mr. Hall (?) was first with Madame Eugène Verdier, Merveille de Lyon, Sénateur Vaisse, Her Majesty, Ulrich Brunner, Etienne Levet, Thomas Mills, La France, Captain

Christy, Le Havre, Innocente Pirola, J. S. Mill, Niphetos, Duke of Edinburgh, Catherine Mermet, Alfred Colomb, John Bright, Madame de Watteville, Fisher Holmes, Comtesse de Nadaillac, Earl of Pembroke, Dupuy Jamain, Jean Soupert, Lady Mary Fitzwilliam. Second, the Rev. F. Page Roberts of Scole; and third, Mr. A. Tate. In class 9, for trebles, Mr. W. J. Grant was first with A. K. Williams, Marie Finger, Marie Baumann, Captain Christy, Lord Macaulay, Etienne Levet, François Michelin, Dupuy Jamain, La France, Duchess of Bedford (a fine triplet), Ulrich Brunner, Louis Van Houtte, Duchesse de Morny, Duke of Edinburgh, Baroness Rothschild, Marie Finger, Marie Baumann, Madame Lambard, Général Jacqueminot, Marie Verdier, and Prince Arthur. The Rev. J. H. Pemberton was second, and Mr. T. B. Hall third. In class 10, for twelve Teas, there was a very sharp competition, the first prize being awarded to the Rev. Hugh A. Berners of Harkstead Vicarage, Ipswich, for a beautiful stand of Catherine Mermet, Comtesse de Nadaillac, Innocente Pirola, Francisca Kruger, Souvenir de Paul Neyron, Comtesse Riza du Pare (without doubt the best bloom I have ever seen of this most uncertain flower), Souvenir d'Elise Vardon, Marie Van Houtte, Princess of Wales, Rubens, Madame de Watteville, and the Hon. Edith Gifford. The Rev. F. R. Burnside and Mr. W. J. Grant were an equal second, and the Rev. F. Page Roberts highly commended. A most beautiful class.

In class 11, for twelve of one kind, dark, the prize was awarded to Ulrich Brunner; second, Alfred Colomb. In class 12, twelve of one colour, light, Marie Finger gained the first and second places, and La France the third. In class 14, for twenty-four, to which the gold medal was awarded for growers in Cheshire and Lancashire, the first prize was gained by T. B. Hall, Esq., for a fine box containing Ulrich Brunner, Louis Van Houtte, Merveille de Lyon, Duchess of Bedford, Madame Isaac Pereire, Général Jacqueminot, Baroness Rothschild, La France, Marie Finger, Dupuy Jamain, Fisher Holmes, Captain Christy, A. K. Williams, François Michelin, Monte Christo, Etienne Levet, Madame de la Place, William Warden, Paul Neyron, Le Havre, Alfred Colomb, Dr. Andry, Eugène Verdier, Madame Lambard. In class 15, for twelve, Mr. A. H. Hodgson was first with Louis Van Houtte, Camille Bernardin, Captain Christy, Dr. Andry, Comtesse de Serenyi, Abel Carrière, Baroness Rothschild, Etienne Levet, Marie Verdier, Madame Rady, François Michelin, Sénateur Vaisse, and Countess of Oxford. It was run very close by the Misses Squarry, who were second with Marie Baumann, La France, Dupuy Jamain, Le Havre, Alfred Colomb, Horace Vernet, Captain Christy, Prince Arthur, Duc de Wellington, Marie Finger, Général Jacqueminot, and Marquise de Castellane. In class 17, for twelve Teas, Mr. T. B. Hall was first with excellent blooms of Anna Ollivier, Madame Margottin, Madame de Watteville, Madame Cusin, Jean Ducher, Catherine Mermet, Marie Van Houtte, Prince of Wales, Souvenir d'un Ami, Comtesse de Nadaillac, Souvenir d'Elise Vardon, and Francisca Kruger. Mr. E. Claxton was second. In this box was also the best Tea in the amateurs' class awarded the silver medal, a fine bloom of Comtesse de Nadaillac. In class 19, for six Teas, Mr. W. C. Hall was first with Madame Lambard, Jean Ducher, Anna Ollivier, Madame Willermoz, Catherine Mermet, and Alba Rosca. In class 20, for Roses with Maidenhair foliage, a prize given by the zealous Secretary, Mr. Chas. E. Hall. The first prize was awarded to T. B. Hall, Esq., and the second to the Rev. Canon Fielden.

Thus ends my record of which I believe to have been the best show, as far as quality is concerned, of the season, and I think the promoters of Rose-growing in Wirral may be congratulated on the great improvement which has taken place in the local classes, which after all is the most important point.—D., Deal.

IPSWICH.

THE summer Show of the Ipswich and East of England Horticultural Society was held in the beautiful grounds of Christ Church Park on Wednesday, July 11th. Unfortunately the weather was most unpropitious, rain falling in torrents during the greater portion of the day, consequently the attendance was very small, and the Society suffered a great financial loss. The exhibits were shown in two splendid marquees, one set apart for Roses and pot plants, the other for fruit and vegetables. The Roses nearly filled the whole of the table in the centre of the tent, and made a most magnificent show. In the open classes for thirty single trusses Mr. B. Cant was first with good blooms, the most noteworthy being Horace Vernet, Ulrich Brunner, Dupuy Jamain, Merveille de Lyon, Marie Finger, and Victor Hugo. Mr. F. Cant was second with fine flowers of A. Colomb, Baroness Rothschild, Her Majesty, L'Exposition de Brie. In the open classes for twelve triplets, Mr. B. R. Cant was first, Mr. F. Cant second, and the Rev. Foster Melliar, Sproughton Rectory, was third. The latter in the opinion of many good judges ought to have been placed second in this class. For the best twelve Teas and Noisettes, open, Mr. F. Cant was first, Mr. B. R. Cant second.

In the amateurs' classes the blooms were exceptionally fine, and a grander show of the queen of flowers has not been seen in East Anglia for some time past. In the thirty-six class the Rev. Foster Melliar was first with grand blooms; the best flowers were Duke of Edinburgh, Thomas Mills, Marie Van Houtte, Horace Vernet. The Rev. Hugh Berners, Harkstead Rectory, was second with neat but not quite such large flowers. Third, Miss Penrice.

For twenty-four blooms, single trusses, Rev. H. Frere, Burston Rectory, Diss, was first; Mr. Palmer, gardener to T. Power, Esq., Drinkstone Park, second. For twelve, Rev. H. A. Berners took first, the Rev. Foster Melliar second.

For six blooms of any Roses Rev. H. Berners was first; and Mr. Palmer second with Duke of Edinburgh.

In the class for twelve Teas and Noisettes Rev. H. A. Berners, who has been showing Tea Roses grandly all the season, and has won seven first prizes, was first with beautiful blooms of Comtesse de Nadaillac, Madame de Watteville, Souvenir d'Elise, Innocente Pirola, Anna Ollivier, Catherine Mermet, Madame Lambert, Marie Van Houtte, Marie Guillot, Edith Gifford, Jean Ducher, Souvenir d'un Ami. Second, Rev. Page Roberts; third, Rev. Foster Melliar. In the class for six distinct varieties Mr. D. C. Orpen first.

Fruit, notwithstanding the late season, was good. Lord Rendlesham (gardener, Mr. Rogers) was first with a good collection, his Peaches and Nectarines being very fine; he took the first prizes for Peaches and Nectarines.

Vegetables were very fine. The collections shown by Mr. Cresswell, gardener to W. Charteris, Esq., of Stoke Park, and Mr. Andrews, gardener to Hon. T. Lowther, were very good.

The stands of cut flowers shown by lady amateurs were beautifully arranged and much admired, the first prize being taken by Mrs. H. E. Archer, and the second and third by Miss Steward, Graham House, and Miss M. E. Turner, Clare Lodge.

NATIONAL ROSE SOCIETY'S SHOW AT DARLINGTON.

JULY 20TH.

WE have been favoured by the following clipping from the *Northern Echo* descriptive of the provincial Show at Darlington.

The promoters of the annual provincial Show of the National Rose Society at Darlington might well be pardoned if they prematurely exulted over the magnificent weather which they believed had favoured their venture of Saturday, for up to three o'clock in the afternoon everything was brilliantly fine, although there were those who spoke ominously of the hot close character of the atmosphere as boding rain. And these latter told an over-true tale. The English climate once more showed up as "fickle as a changeful dream, fantastic as a woman's mood." It was about the time for excursionists to put in appearance when a sharp shower of straight-down rain obtruded its unwelcome presence on the scene, although Southend Park—wherein the Show was held by the kind courtesy of the Misses Pease—with its noble trees, is well adapted for affording shelter in a passing thunderstorm. Hereafter, for the rest of the day the sky wore a leaden look, and the air was extremely sultry.

The last occasion upon which the National Rose Society honoured Darlington in this way was in July, 1882, when the entries were gratifyingly large. To indicate the extent to which the cultivation of the Rose has increased throughout the country we may compare that figure with the blooms which were now entered. There were upwards of 50 per cent. more entries for Saturday's Show than for that in 1882. Unfortunately the season in the north is at least a fortnight late, and the consequence was that very many rosarians in the district of Darlington were unable to stage the blooms they had intended, so that the actual exhibits fell short of the entries. For example, there was Mr. E. R. Whitwell, the noted grower of Barton. He had entered several classes, but at the last moment found it impossible to cut Roses of tolerable form and colour sufficient to fill a single stand. Taken as a whole, the blooms that were shown did not comprise such fine individual specimens as in previous years, nor was the quality quite so good as has been seen at shows held this year elsewhere. In spite of the backward season, however, the collection of specimens, set out most effectively in a marquee 60 yards in length, pleased the eye with its effect of rich and varied hues.

It is safe to say that the best stand in the Show was that which won the amateurs' Jubilee trophy, and put up by Mr. T. B. Hall, Rock Ferry, Birkenhead, who carried off the challenge trophy last year. A feature of the Exhibition was the distinct hit made by Messrs. Harkness & Co. of Bedale, to whom again fell the challenge trophy (valued at £50) in the professional division. Their blooms were unexceptionable for cleanliness and finish, although they had not the substance of those of the southern growers, who have had better weather than their northern competitors. Naturally the Tea Roses were deficient, their outer leaves being generally weather-beaten, except in the case of Messrs. Harkness, who had the advantage over southern growers of being able to cut overnight, and whose blooms were firm and fresh, and proved very successful on the stands. This firm was entitled to every praise for the admirable way in which they have sustained the reputation of the north.

Besides the challenge trophies already referred to, the National Society offered three silver medals—one for the best Hybrid Perpetual, one for the best Tea or Noisette in the amateur class, and one for the best box of Roses shown in the district classes. The first-named medal was given to Mr. E. B. Lindsell for Her Majesty, a bright satiny Rose, with flowers exceptionally large, very full, and the petals most symmetrically arranged. The medal for the best Tea Rose fell to the Rev. F. R. Burnside, Gloucestershire, for Marie Van Houtte, a large and full bloom, charming in its combination of yellow and peach. Mr. A. Whitton, Bedale, took the third medal for the best box shown by district growers. The gold medal of the National Society was offered for three trusses of any new seedling Rose not yet in commerce; but there were no entries in the class.

The duties of judging were performed by the nurserymen for the amateur classes, and by the amateur exhibitors for the professional divisions. The Rev. H. Honeywood D'Ombraim was in attendance, and expressed himself thoroughly satisfied with the general arrangements,

for the excellence of which warm praise is due to Mr. E. R. Whitwell and Mr. G. S. Byers, the local Secretaries.

Appended are the names of the Judges, together with their awards:—

Nurserymen's Divisions.—Rev. J. H. Pemberton, Mr. E. R. Whitwell, Mr. T. B. Hall, Lieut.-Col. Standish Hore, Mr. W. E. Boyes, Mr. James E. Backhouse, Rev. Page-Roberts, Mr. W. E. Hall, Rev. H. H. D'Ombraim (Secretary), and Rev. Foster-Melliar. Amateur Sections.—Messrs. J. Burrell, W. Burch, H. W. Williams, G. Paul, G. Prince, W. F. Cooling, J. Jefferies, Harkness, jun.

Nurserymen (open).—Thirty-six dissimilar, single trusses. First and challenge trophy, Messrs. Harkness & Son, Bedale. Second, Messrs. Paul & Son, Cheshunt. Third, Mr. B. R. Cant, Colchester. Fourth, Messrs. Keynes, Williams & Co., Salisbury. Seventy-two dissimilar, single trusses, Messrs. Paul & Son, Cheshunt. Second Mr. P. R. Cant. Third, Messrs. Cranston & Co., Hereford. Thirty-six dissimilar, three trusses of each, Messrs. Paul & Son. Second, Mr. B. R. Cant. Third, Cranston & Co. Thirty-six dissimilar, single trusses, Messrs. J. Jefferies & Son, Cirencester. Second, Mr. W. H. Frettingham, Beeston, Notts. Third, G. & W. H. Burch, Peterborough. Fourth, J. Burrell and Co., Cambridge. Eighteen dissimilar, three trusses of each. Messrs. J. Jefferies & Son. Second, Messrs. G. Cooling & Sons, Bath. Third, Messrs. Burch. Fourth, Messrs. Keynes, Williams & Co.

Amateur Division.—Twenty-four dissimilar, single trusses, first and challenge trophy, Mr. T. B. Hall, Rock Ferry, Birkenhead; second, Rev. J. H. Pemberton, Romford, Essex; third, Mr. S. P. Budd, Bath; fourth, Mr. A. Slaughter, Steyning, Sussex. Thirty-six dissimilar, single trusses, Rev. J. H. Pemberton; second, Mr. T. B. Hall. Twelve dissimilar, three trusses each, Rev. J. H. Pemberton; second, Mr. T. B. Hall; third, Mr. S. P. Budd. Twenty-four dissimilar, single trusses, Mr. E. B. Lindsell, Hitchin; second, Rev. A. Foster-Melliar, Ipswich; third, Mr. E. Mawley, Berkhamstead, Herts; fourth, Mr. A. Slaughter. Twelve dissimilar, ditto, Lieut.-Col. F. Standish Hore, St. Asaph; second, Mr. W. Hutchinson, Kirbymoorside; third, Mr. W. E. Hall, Birkenhead; fourth, Rev. F. Page-Roberts, Scole, Norfolk. Six dissimilar, ditto, Miss Alice M. Lucas, Hitchin; second, Mr. H. V. Edwards, Machworth, Derby.

Division E (open to residents within thirty miles of Darlington, who have never won a first prize at any exhibition of the National Rose Society held elsewhere than at Darlington), twelve dissimilar, single trusses, Mr. A. Whitton, Bedale; second, Mrs. Maynard Proud, East Layton Hall, Darlington; third, Mr. D. Green, Seorton. Six dissimilar, ditto, Mr. W. E. Brown, 22, Milton Street, Darlington. Extra Class—Six new Roses, distinct, single trusses, Rev. A. Foster-Melliar.

Tea and Noisette division (open).—Twelve Teas or Noisettes, three trusses of each. Messrs. Harkness & Son; second, Mr. G. Prince, Oxford; third, Rev. F. R. Burnside, Chipping Campden, Gloucestershire; fourth, Mr. B. R. Cant. Nurserymen, eighteen ditto, single, Mr. G. Prince; second, Mr. B. R. Cant. Two ditto, ditto, Messrs. Harkness & Son; equal seconds, Messrs. J. Jefferies & Son and Messrs. Keynes, Williams and Co.; Fourth, Messrs. Paul & Son. Amateurs, twelve single trusses, Rev. F. R. Burnside; second, Mr. E. B. Lindsell; third, Rev. F. Page-Roberts; fourth, Mr. A. Slaughter. Six ditto, Rev. A. Foster-Melliar; second, Mr. E. Mawley; third, Colonel Standish Hore; fourth, Mrs. Times, Hitchin.

Open Division.—Twelve new Roses, dissimilar, single trusses, Paul and Son. Twelve single trusses of any yellow Rose, Mr. G. Prince. Second, Mr. B. R. Cant. Third, Messrs. R. Mack & Son, Catterick. Twelve white Roses, Messrs. Burch. Second, Mr. S. P. Budd. Third, Mr. G. Prince. Extra prize, Rev. F. P. Roberts. Twelve single crimson ditto, Messrs. Cranston & Co. Second, Mr. S. P. Budd. Third, Mr. W. H. Frettingham. Twelve dark crimson ditto, Messrs. Cranston and Co. Second, Messrs. G. Cooling & Sons. Third, Mr. B. R. Cant. Twelve blooms, six of each, Harkness & Son. Second, Mr. B. R. Cant. Equal third, Mr. G. Prince and Messrs. Burch.

STRAWBERRIES FOR FORCING.

I AM pleased to see that Mr. Bardney thinks much more highly of saving late autumn runners for forcing than he was at first disposed to do. Allow me to thank him for again drawing attention to it, and we shall expect to hear of the success of his proposed experiment. His soil being light, I have no doubt he will succeed much better than I should do were I to adopt the same plan. The soil here is just opposite, and if I were to do as he proposed, by the middle of June I should have very gross plants, each lifting with more soil than could be crammed into a 6-inch pot. This year I left my plants in the nursery rows till June, and placed them direct into their largest pots, and I regret to say my plants are not so good as usual. The check they received in potting has thrown them back considerably. I think in most soils it would be quite unnecessary to pot before planting out in the autumn. On the other hand, on strong soils I think it is important that the plants be placed in 60's early in spring to prevent a gross growth, and have the plants so that they can be placed in their fruiting pots without a check any time when convenient during June.

Allow me here to disclaim all credit of having originated this excellent plan of treating plants for forcing. It is one of the many "wrinkles" I have gleaned from these pages during the last twenty-five years I have been a reader of them. I have practised it for eight or nine years. Perhaps some one who has a pile of back volumes can trace it to its source, and let honour be given to whom it is due.—R. INGLIS.

THE programme of the AUSTRIAN FRUIT EXHIBITION, to be held at Vienna, September 29th to October 7th, has been already referred to, but fuller particulars have been received, from which it appears that three sections—namely, for fruit, fruit products, and implements for fruit cultivation are set apart for Austrian exhibitors. The two others for “Competitive fruit drying,” and “Machinery or implements for the cultivation of and utilisation of fruits,” are international. In the circular just issued by Count Henry Attems Leechwald, Graz, Styria, full particulars are given in English respecting the two latter sections, the conditions of competition, space hire, prizes, &c.

— FLORAL DECORATION.—We learn that on the occasion of the visit of the Prince and Princess of Wales to Holloway to open the Great Northern Hospital, the whole of the floral decorations and three bouquets were supplied gratuitously by Mr. B. S. Williams; Victoria and Paradise Nurseries, Upper Holloway, N.

—“W. J. G.” writes:—“There is now in the garden of Beaconhill House, Exmouth, Devon, a tree of EUCALYPTUS GLOBULUS, which in a few days will be a beautiful sight. At present there are some hundreds of blooms, but a vast number of buds are expanding. The height of the tree is about 30 feet, and at 6 feet from the ground measures 24 inches in circumference. It was planted about seven years ago. Does not such a specimen speak well for our mild climate?”

— TRADE NOTICE.—We are informed that Mr. A. W. Crews having relinquished the managership of the Chad Valley Nurseries, Birmingham, has entered into business with Mr. A. C. Cox (late of Messrs. Hugh Low & Co.) at Gloucester. The address of the firm is Crews, Cox and Co., Southgate Street, Gloucester.

— THE HEAVIEST STRAWBERRIES.—Our correspondent “Saxoring” wishes to know the heaviest weights of individual fruits of Strawberries grown as a crop not for show or prizes, and whether any have been known weighing as much as 4 ozs. each. He says, “I have a lot this year 1½ oz. to 1¾ oz. each, and numbers of Dr. Hogg weighing 1 oz., but not one of 2 ozs.” Marguerite is a large-fruited variety, and Mr. Goldsmith, at Kelsey Manor, Beekenhams, has had numerous fruits this season exceeding 2 ozs., while it is recorded that some fruit of this variety have been obtained weighing 3½ ozs. Perhaps some of our readers can give further information on this point.

— MESSRS. CORRY, SOPER & Co. (Limited), 16, late 18, Finsbury Street, write:—“With much regret we have to announce the death of MR. GEORGE ROBERT SOPER, a member of our firm, which occurred on the 6th inst., at 300, Amhurst Road, Stoke Newington, N., after a long and painful illness.”

— THE KEW BULLETIN for July contains much interesting matter, the first article dealing with the Bhabur Grass (*Ischemum angustifolium*), which is said to approach Esparto in habit and usefulness for paper-making. A chapter is devoted to the Cayman Islands and their products; another deals with Valonia in Cyprus, giving analyses of the acorn cups from several species of Oak imported from Cyprus for tanning purposes. A long article is devoted to the Prickly Pear (*Opuntia*) in South Africa, describing its value as fodder for sheep and ostriches, its cultivation, the species of *Opuntia* used, the cochineal industry, and the production of alcohol from Prickly Pears. The Star Anise, *Illicium verum*, with an illustration, completes a useful number.

— GRAPES AT ELDFORD.—“Visitor” sends the following paragraph:—“In July of last year some remarks appeared in the columns of the Journal respecting the fine quality of the Eldford Grapes as grown by Mr. J. Udale, and in a brief and hurried visit just paid by me to these fine old gardens I was glad to find that such high quality had been more than maintained during the present season. The bunches are of large size, and the berries exceptionally so. Mr. Udale told me that from careful measurements he had made he found them (Black Hamburgs) to measure from 1 to 1½ inch in diameter. The colour is very dense

and deep, the bunches solid, and the berries have the peculiar “hammered” appearance prized by many cultivators. As they are likely to appear upon more than one exhibition table we are almost certain to hear further of these fine examples of Grape culture.”

— JUST as we go to press we regret to learn that Mr. F. WHITBOURN, OF GREAT GEARIES, ILFORD, ESSEX, died suddenly on Wednesday morning. He had long been in feeble health, but was out the day before he died. For many years Mr. Whitbourn has given much encouragement to horticulture and floriculture, and his gardener, Mr. J. Douglas, is widely known as a successful exhibitor.

— “I WISH to call attention to VERONICA TRAVERSI,” writes Mr. T. Record, “because at this time of the year, when there are few hardy shrubs in flower, this is most beautiful. It is of dense habit, with a profusion of short-jointed shoots and pure white flowers, but when not in flower its narrow and pointed foliage and compact habit of growth makes it a desirable shrub. It seems also to be adapted for planting near the sea coast, for from Eastbourne along the coast to Scaford, Newhaven, and Beachy Head, it is found in most gardens, and appears to be quite as much at home in such places as the green *Euonymus*. The Veronica does well inland also, and may be depended upon to grow in almost any soil, and will successfully bear moving at any time of the year when not in full growth and flower. It roots freely from cuttings, which are best taken from the points of the shoots any time after growth is completed. Inserted in nursery rows under the protection of a wall I have not lost one plant out of a hundred.”

— WRITING from BUILTH, “T. T.” says, “We have a LILIUM GIGANTEUM in flower here; it has produced three flower stems of about 9 feet high, with eight to ten blooms on a spike. It is planted around the side of a border. The natural soil here is light and very shallow, not more than 6 inches of soil in places in the garden; it lies on the rock.” This noble Lily has also been flowering well at Kew this season in a somewhat sheltered nook in the rockery, and in Mr. G. F. Wilson’s garden at Wisley.

— CHRYSANTHEMUMS AND THE WEATHER.—“C. O.” writes, “The recent dull and showery weather is causing a very rapid and vigorous growth this season, and I fear many of the naturally grown plants will be long-jointed and sappy, and attain undue height. Under the circumstances it would be as well to abstain from giving any stimulants and water sparingly during the absence of sunshine to induce as hard and solid a growth as possible. Strict attention should be paid to tying and securing the growth of the laterals as they extend, cutting away all but the required number to be left.”

— AT the ordinary weekly meeting of the members of the WAKEFIELD PAXTON SOCIETY, held at the “Saw Hotel,” Councillor Milnes, the President, was in the chair, and Mr. Arthur Goldthorpe, who is one of the Vice-Presidents, occupied the vice-chair. There was a good attendance of the members. The annual display of Roses should have been made, and a discussion upon the queen of flowers opened by Mr. G. Bott of Walton, a well-known amateur rosarian, but in consequence of the unseasonable weather the blooms were not quite ready for exhibition, and the show and discussion on Roses was adjourned until the next meeting. Mr. Hudson, gardener at Sandal Grange, read a very interesting paper on “The Foxglove,” which he strongly recommended amateur gardeners to grow in their borders and on their rockeries.

— DIET FOR HOT WEATHER.—Mr. W. S. Manning writes:—“Fresh fruit may be taken to any extent, without fear of any ill results, if good whole-meal bread and other cereal foods are taken with them. The *Lancet* and other medical journals have been speaking out of late strongly in favour of ripe raw fruits, early in the morning especially. They afford a very beneficial gentle stimulant to the mucous membrane of the stomach, rendering dyspepsia in every form almost impossible. Let your readers, therefore, who may be subject to any of the many “ills that flesh is heir to,” (mainly through ill-chosen food probably) give a steady trial to the Edenic diet of fruit and grain, and they will find that, whilst they are thus doing their best to encourage increased supplies of the most remunerative crops for the farmer, in taking ripe fruit for food and drink, they will be at the same time simply eating themselves out of their chronic ailments, especially such worrying sorts as indigestion and rheumatism, on the wholesomest, heartiest, and pleasantest fare that science can suggest.”

— In the course of an article on the DISPERSION OF SEEDS AND PLANTS, contributed by Mr. D. Morris to *Nature* recently, he had the following note:—"The Orange tree was introduced to Jamaica more than a hundred years ago. It is now found practically wild over the settled parts of the island, and the fruit is exported to the value of nearly £50,000 per annum. Up to quite recently very few trees were planted. Nearly the whole were sown by the agency of frugivorous birds, who carried the seeds from place to place and dropped them in native gardens, Coffee plantations, Sugar estates, and grass lands. In such localities the Orange trees grew and flourished, and now a demand has arisen for the fruit in the United States an important industry has been established, the active agents in which have been birds. The agency of birds in the distribution of the seeds of plants is too large a subject to be discussed at length here. A valuable contribution of facts in this direction has lately been made by Dr. Guppy in his important work on the Solomon Islands. As the most recent addition to our knowledge of what takes place in oceanic islands at the present time it deserves careful attention. It will suffice only to quote one or two sentences:—"Whilst through the agency of the winds and currents the waves have stocked the islet with its marginal vegetation, the fruit pigeons have been unconsciously stocking its interior with huge trees, that have sprung from the fruits and seeds they have transported in their crops from the neighbouring coasts and islets."

ROYAL HORTICULTURAL SOCIETY.

JULY 24TH.

THE Drill Hall, James Street, Westminster, was well filled with exhibits on Tuesday last, as in addition to the groups and plants and fruit submitted to the Floral and Fruit Committees, the National Carnation and Picotee Society held its annual Show on the same date. The competition for the prizes in the classes provided by the latter was not, however, so keen as usual, and consequently the exhibits did not occupy a very large space, but the non-competing groups amply compensated for this deficiency. Four tables extending nearly the whole length of the hall were filled with plants and flowers, a cross table at the top being devoted to fruit and vegetables, of which there was a larger display than has been the case at recent meetings.

FRUIT COMMITTEE.—Present: Dr. Hogg in the chair, and Messrs. Veitch, J. Lee, J. Cheal, R. D. Blackmore, J. Burnett, G. T. Miles, W. Marshall, W. Denning, T. B. Haywood, T. J. Saltmarsh, J. Willard, J. Smith, J. Roberts, and Dr. Hogg.

Messrs. J. Veitch & Sons, Chelsea, exhibited a collection of fruit comprising very handsome examples of the large dark coloured Strawberry Waterloo, Raspberry Lord Beaconsfield (a dark-fruited variety), Raspberry Superlative with large, bright, conical fruits, a fine variety, thought by some to resemble *Semper Fidelis*; but the decision of the Committee was reserved until the next meeting at Chiswick. The cut-leaved White Dutch Currants, Cleveland Bigarreau, Kentish and May Duke Cherries, Negro Largo Figs in pots, and several cord-trained Red Currants completed the collection (vote of thanks). Messrs. Paul & Son, Cheshunt, sent several fruits, amongst which samples of *Elæagnus longipes edulis*, some being preserved; in the fresh state the small oval fruits are exceedingly acid and astringent, not unlike the common Sloe, and certainly not more tempting. Fine bunches and berries of La Versailles Red and White Currants were shown, and fruits of the late prolific Strawberry Helena Gloede.

Mr. W. Allan, gardener to Lord S. field, Gunton Park, Norwich, was deservedly awarded a cultural commendation for a collection of extremely handsome well grown Strawberry fruits, the following varieties being represented:—Unser Fritz, very large; Sir C. Napier, British Queen, Crimson Queen, James Veitch, and Dr. Hogg. Mr. A. G. Nichols, Nunham Park Gardens, Abingdon, showed a seedling green-flesh Melon which was unripe, but the Committee desired to see it again. Mr. D. Tallerman exhibited a number of Strawberries in cardboard boxes to illustrate the De La Vergue cold air system of refrigerating. The fruits had been gathered in Essex on July 13th, twelve days before, and were as fresh and firm as if they had only been gathered a few hours. They, however, possessed very little flavour, and as it could not be determined whether this was due to the process or not, a series of experiments was suggested that will definitely determine the value of the system. It was considered very satisfactory as regards the preservation of the fruits, and it is believed by the exhibitors that they can be kept for two months, retaining both colour and flavour. From the Society's garden at Chiswick came twenty-one dishes of Red and White Currants, including Red and White Dutch, Common White, Champagne, Red Cherry, and Defiance, which is very similar to La Versailles. Mr. Walker of Thame showed pods of Duke of Albany and Improved Telegraph Peas that did not obtain any special notice.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. Shirley Hibberd, H. Herbst, W. Bates, J. Fraser, W. Wilks, T. Baines, R. D. An, C. Noble, C. Pilcher, H. Ballantine, J. Dominy, H. M. Pollett, J. O'Brien, E. Hill, G. Paul, and B. Wynne.

From Mr. G. F. Wilson's garden at Wisley came some handsome flowers of choice Lilies, *Lilium giganteum* and *L. Browni* being of

remarkable merit, and very rarely are such large blooms of the latter seen; the *L. giganteum* flowers also had more deeply coloured stripes than is usually seen in this fine Lily. The others were *L. Martagon* var. *dalmaticum*, very rich and dark; *L. elegans*, *L. sanguineum*, *L. eruentum*, *L. avenaceum*, *L. concolor*, and *L. Coridion*, only a few from an uncommonly rich collection. T. B. Haywood, Esq., Woodhatch Lodge, Reigate, showed blooms of the Rose Margaret Haywood, a sport from Clemence Joigneux, which was obtained three years ago, and is now quite fixed. The blooms are of fine shape and substance, of a soft rosy tint, not unlike that of La France, but resembling its parent in general style. It is of strong habit, free, and a good autumnal Rose. The variety possesses one admirable quality too often almost absent in new Roses—namely, an exquisite and powerful fragrance. A vote of thanks was awarded for it, but it won the National Rose Society's silver medal last year at Reigate.

Mr. J. C. Cowley, Studley House Gardens, Hammersmith, exhibited several Orchids, amongst them being *Miltonia vexillaria superba*, the flowers small but highly coloured, with a deep maroon blotch at the base of the lip, partly surrounded by a white band, the other portion of the flower being rosy crimson. It is very distinct and evidently free. Plants in flower were also shown of *Dendrobium Macartheae* and *Cattleya crocata*, the latter having neat white flowers with a deep gold throat to the lip. Votes of thanks were accorded for all these. C. Dormar, Esq., Laurie Park, Sydenham, sent a plant of *Epidendrum vitellinum majus* with a large spike and fine flowers (vote of thanks), also *Anguloa Ruckeri alba* (certificated). R. B. Lemon, Esq., Moat Lodge, Beckenham (gardener, Mr. Adams), was adjudged a vote of thanks for *Odontoglossum cristatellum*, with deep brown sepals and petals, yellowish at the base, not remarkably beautiful, but distinct from most other forms of the same section. Messrs. Sander & Co., St. Albans, again exhibited a plant of *Lælia Eyermanniana*, a supposed natural hybrid between *L. majalis* and *L. autumnalis*; the flowers of a soft rosy mauve colour and possessing some characters of each species, but most of the latter (vote of thanks). Bollea Wendlandiana, with large fleshy yellow flowers and a white column. Messrs. Seger and Tropp, Lordship Lane, East Dulwich, showed *Cypripedium Stonei* acrosepalum, a variety with long dark sepals and petals, but not distinguishable from many ordinary forms of *C. Stonei*. Mr. C. Noble, Bagshot, sent a large plant of *Spirea palmata* well flowered, and Messrs. Laing and Mather, Kelso, showed a plant of Carnation R. H. Elliot, salmon striped with crimson.

Messrs. W. Paul & Son, Waltham Cross, exhibited several new H.P. Roses, one of which, Duchess of Albany, was certificated; the others were Brilliant, a fine richly coloured crimson buttonhole Rose, and Marchioness of Lorne, rosy crimson, a larger bloom than the latter. Mr. W. Gordon, Twickenham, exhibited flowers of *Lilium elegans* in several varieties, reddish orange, yellowish, and several intermediate shades; a fine collection of Japanese Irises also came from the same nursery, two being certificated. Mr. T. Smith, Newry, sent a so-called hybrid *Lychnis* from *L. flos-Jovis* and *L. coronaria*, but it was much like the last named. From Mr. A. Scott, Cambridge, came a *Lobelia* with light blue flowers and yellowish leaves, distinct, but not very beautiful. Messrs. Cannell & Sons, Swanley, showed a collection of flowers of Ivy-leaved Pelargoniums, a primrose-coloured Sunflower, and early pale yellow Chrysanthemum, named L'Ami Conderchet, a white variety of *Salvia patens*, and several good Pentstemons (vote of thanks). Messrs. Kelway & Sons, Langport, had a large collection of Delphiniums, Gaillardias, Amaryllises, and hardy flowers (bronze medal). Mr. B. R. Cant, Colechester, exhibited six boxes of Rose blooms exceedingly fresh and beautiful, representing most of the best exhibition varieties (silver medal). Messrs. J. Cheal & Sons, Crawley, contributed a collection of single and Pompon Dahlias in many fine varieties, also some Tuberous Begonias and Roses. Most of the former were arranged in Cheal's patent wire flower supports, which are very conveniently constructed for holding flowers in vases, several branches radiating from a central stem, each furnished with a small ring for holding the flower in the required position.

A magnificent group of Ferns was contributed by Messrs. W. & J. Birkenhead, Sale, near Manchester, for which a silver Banksian medal was awarded, but in the opinion of many it merited a higher honour. There were about 1000 plants in over 360 species and varieties, including a choice assortment of both greenhouse and hardy Ferns, furnishing, indeed, one of the most interesting features of the meeting. Of Selaginellas and Adiantums alone sixty species or varieties each were shown, and the twenty forms of Davallias included all the types from the largest to the diminutive *D. parvula*, like a small Selaginella. The climbing Lygodiums were also admirably represented from tall plants of the comparatively gigantic *L. diebotomum*, a bold and distinct Fern with large palmate fronds, to the smallest of all, *L. microphylla*. The delicate and exquisitely beautiful *Notholaenas* and *Cheilanthes* were numerous. There were also many choice forms of *Athyrium*, *Scolopendrium*, to which we must refer more fully in another issue. Three were, however, selected for certificates, and are noted below. A silver-gilt Banksian medal was awarded to Messrs. Paul & Son for an extensive and brilliant group of Roses and hardy flowers most effectively arranged, and silver medals were adjudged to Mr. T. S. Warr, Tottenham, for a smaller but similarly choice group of hardy flowers, and to Mr. B. S. Williams, Upper Holloway, for a grand group of Orchids, Ferns, Palms, with valuable or rare stove and greenhouse plants in variety. Messrs. Veitch & Sons had several extensive collections, including a group of *Clethra alnifolia*

in 48 and 32-sized pots, neat bushes, bearing numbers of long spikes of white flowers; the curious New Zealand *Notospartium Carmichaelæ* with rosy purple Pea-shaped flowers in dense clusters on leafless recd-like stems; a reddish-flowered *Yucca* named *obliqua*; *Rhododendron* flowers, Japanese Irises in numerous fine varieties, and a collection of Carnations and Picotees comprising all the best varieties in cultivation, represented by fine clear handsome blooms. Messrs. E. Collins & Son, Willesden, sent a group of white Carnations and scarlet *Pelargoniums*; Mr. C. Turner, Slough, a group of Carnations in pots, and Mr. F. Ross, Pendell Court Gardens, brought flowers of *Bignonia chirere*.

CERTIFICATED PLANTS.

Carnation Elaine (J. Douglas).—A border variety with large pure white substantial and well-formed blooms. A valuable acquisition.

Angulea Ruckeri alba (C. Dorman, Esq.).—A variety with wax-like flowers, pure white except for a few purplish lines in the lip, similar to *Ruckeri* in form and habit.

Rose Duchess of Albany (W. Paul & Son).—A handsome H.P. variety of the *La France* type, but much darker in colour; excellent habit, very free, and altogether a capital Rose. We have previously referred to this variety on several occasions.

Saccolabium caeleste (B. S. Williams).—A beautiful species, with short channelled leaves 5 or 6 inches long and 1 inch broad. The flowers small, in compact erect racemes 6 inches long, the sepals and petals white tinged and tipped with purple, the lip bluish purple.

Rhododendron Purity (J. Veitch & Sons).—One of the greenhouse hybrid section obtained from a cross between *R. Taylori* and *R. Teysmanni*, and of several seedlings flowered from the same cross this is the only one that has white flowers. The corollas are large with broad rounded lobes and pure white, a decided advance, as most others hitherto obtained have had a slight tinge of colour. It is interesting also as being obtained from parents with rosy crimson and orange coloured flowers.

Oreocome Candollei (C. Noble).—A hardy herbaceous umbelliferous plant 4 or 5 feet high, with large much-divided leaves and large umbels of light coloured flowers. The foliage is its chief attraction.

Stuartia pseudo-Camellia (J. Veitch & Sons).—A Japanese shrub included in the *Camellia* family, having narrow lanceolate leaves and large white flowers of five broad rounded silky petals slightly frayed at the margin, and having a dense cluster of stamens bearing yellow anthers in the centre.

Rose Paul's Cheshunt Scarlet (Paul & Son).—Exhibited as a decorative variety, described as very free in growth and flowering, the colour a brilliant crimson scarlet, suggestive both in form and colour of *Général Jacqueminot*.

Lælia Amesiana (Baron Schröder).—One of the *C. Mendeli* type, with bluish sepals and petals, the lip broad and fringed, the basal half pure white, the apical portion deep rich crimson. The flower is well formed, and the colour boldly marked.

Iris Kämpferi Kaiser Wilhelm (W. Gordon).—One of the beautiful Japanese Irises with broad equal divisions, white, streaked with purple.

Iris Kämpferi Enterprise (W. Gordon).—Similar to the above, except that the flowers are more deeply streaked with purple.

Scelopendrium cristatum (W. & J. Birkenhead).—One of the crested forms of Hart's Tongue Ferns, dwarf and compact in habit, the cristation regular and pretty.

Lastrea montana ramo-coronans (W. & J. Birkenhead).—Another elegant crested Fern, both the pinnae and the tips of the fronds being neatly tufted or divided.

Nothochlana Mulleri (W. & J. Birkenhead).—Very distinct, the fronds pinnate, 8 to 9 inches long, the pinnae oval, green, partially covered with brownish scales, the under surface densely covered in the same way. The young fronds have a whitish appearance.

COUNCIL AND GENERAL MEETING.—A report was read from the Chiswick Committee concerning the National Apple and Pear Conference to be held at Chiswick Gardens from the 11th to the 18th October, and a schedule, which may be had from Mr. Barron, was drawn up and agreed to. It was resolved that the Secretary have a proof of the new by-laws printed and circulated amongst the members of the Council and the Fellows' Committee, and that a meeting be called by Mr. Deal to consider the corrections and alterations.

At a General Meeting of the Society, held in the Council Room, 111, Victoria Street, S.W., Robert Hogg, Esq., LL.D., F.L.S., Vice-President, in the chair, the following candidates were duly elected Fellows—viz., Louis E. Anagnier, W. Handel Cannon, Richardson Evans, Geo. Gar-side, jun., Maurice Holtze, Francis P. Pascoe, James Seeger, and Thomas E. K. Shield.

BLUE GUM TREES.

It is not often that we see the Blue Gum of Australia (*Eucalyptus globulus*) in a luxuriant condition in this country after being planted out for more than one season, our winters usually killing them; but in the garden of the Rev. C. L. Acland of Colchester there is one now about 10 feet in height, with most luxuriant foliage. It has been planted out three years and flowered last year. We believe Mr. A. Smee, who is a great lover of this plant, has to renew his every year. Mr. Smee's plants are in front of his windows to prevent the flies entering his rooms. They do not like the aroma.

A great feature in the Rev. Mr. Acland's flower garden is that a bed is devoted to *Acanthus*, another to *Bamboos*, another to *Polygonum*,

Aralias, &c. No strict old-fashioned bedding-out system is adhered to, while wherever it is possible ornamental Grasses are sown thinly, these drooping over *Saxifragas*, *Sedums*, &c., out of flower, give an airy effect which might be well copied. With the exception of few there is no need to renew every year.—F. H.

RHODODENDRON COLLETTIANUM.

THIS is the proper name of the shrub represented in the accompanying woodcut, and which was distributed under the name of *R. afghanicum*, the latter, however, being a new and distinct species from the same region. It is said to be poisonous, and differs from the subject of our note by its campanulated corolla and long exerted bent style. In *R. Collettianum* the style is very short, the flowers in medium-sized bunches of 8 to 12 or more, white tinged rose. In a note Dr. Aitchison says, "In most of its characters it closely approaches *R. anthopogon*, from which it differs in its large stature, large straight flowers, and in the tube of the corolla being hairy all down the inside." It reaches 10,000 to nearly 13,000 feet above sea level at Shéndtoi to the ridges of Sikaram, commencing at near the limit of trees, and mixed

FIG. 8.—RHODODENDRON COLLETTIANUM.

with masses of Junipers, forming large thickets. It has proved perfectly hardy and flowered for the first time in the rockery at Kew, where it has been planted out since 1886. For rockeries, or where dwarf shrubs are required in the border, this will be found a valuable acquisition. It will be found very useful for hybridising purposes, possibly giving its dwarf habit and hardy nature to some of the better flowered sorts.—D.

THE NATIONAL CARNATION AND PICOTEE SOCIETY.

JULY 24TH.

As most growers expected, the Metropolitan Show, held on Tuesday last in the Drill Hall, James Street, Westminster, was much smaller than usual, for the simple reason that few had been able to get their blooms sufficiently out for exhibition. Good blooms were, however, included in the leading stands, though there were many irregular specimens amongst the second and third prize blooms. Only one certificate was awarded, and this was adjudged for one of Mr. Douglas's seedlings light purple-edged Picotee named *Silvia*, of good substance, clean petals, and with a well defined edge.

CARNATIONS.

Class A, twenty-four blooms, not less than twelve dissimilar varieties. —Two only were in competition in this the most important class, a result that can hardly be considered satisfactory in face of the fact that

five prizes value 50s., 40s., 30s., 20s., and 10s. respectively were offered. The contestants were those old opponents, Messrs. C. Turner, Royal Nurseries, Slough, and James Douglas, gardener to F. Whitbourn, Esq., Great Gearies, Ilford. Many stubborn battles have been fought between these famous growers of florists' flowers with varying results. On the present occasion victory rested with the trade grower, and he was unquestionably several points ahead of his opponent. Mr. Turner showed the following varieties, the names being read from left to right:—Back row—Sarah Payne, Mars, H. K. Major, Juno, E. S. Dodwell, H. K. Major, and Sybil. Middle row—John Keat, James Taylor, James Mackintosh, Mrs. Brown, Henry Cannell, Jessica, James Macintosh, and Mrs. Power. Front row—Mayor of Nottingham, Wm. Skirving, John Keat, Sir G. Wolseley, Mrs. Power, Prince George of Wales, Wm. Skirving, and Clipper. Considering the late and trying season this stand was of great excellence, and several of the blooms were of a very high order, Juno, for instance; Sarah Payne, Jas. Mackintosh, and Clipper were also beautiful examples. Mr. Douglas staged the following:—Back row—Jas. Douglas (2), Sybil (2), Matador, Squire Potts, a most beautiful bloom, one of the best in the Show, and two seedlings. Middle row—James Merryweather (sport), Sportsman, Thalia (2), Florence Nightingale, and two seedlings. Front row—Matador, Admiral Curzon, Henry Cannell, Jas. Merryweather, Florence Nightingale, and three seedlings.

Class B, twelve blooms, dissimilar.—In this class again there were but two competitors, the first prize falling to Mr. Douglas, and the second to Mr. H. W. Headland, The Firs, High Street, Leyton. The first named staged the following:—Back row: James Douglas, an even and highly coloured bloom; Sybil, larger, brighter and good; Mrs. Gorton, and Thalia. Middle row: a pink and purple seedling, Matador, Florence Nightingale, and John Bull, a fresh, smooth, and bright flower. Front row: Sportsman, Admiral Curzon (well coloured), Duc d'Aumale, and a seedling. Generally considered, the stand was of good average excellence. Mr. H. W. Headland is not perhaps an experienced exhibitor, and he will doubtless on future occasions avoid the error of using cards or collars so large and obtrusive as to spoil the effect of some of his finest blooms. Good flowers do not need such ornamentation as was here provided in the form of very large frilled collars. The flowers were of excellent quality, and of the twelve varieties shown—namely, William Skirving, Diana, Harrison Weir, Miss Gorton, Thalia, Sarah Payne, Sybil, Fred, Sportsman, James Douglas, Florence Nightingale, and Matador, the first, sixth, seventh, and tenth named were exceptionally fine. Sybil was splendid; it was a very large, symmetrical, bright bloom, and undoubtedly one of the best in the Show.

Class C, six blooms, dissimilar, six prizes.—This brought four competitors, but only one stand approached the average in point of quality. This was the collection of Mr. C. Phillips, Hamilton Road, Reading, who secured an easy victory. The varieties shown were Tom Power, Wm. Skirving, Thalia, Jas. Douglas, J. D. Hextall, and Mrs. W. H. May. Mr. C. Henwood, also from Hamilton Road, Reading, was placed second, but two blooms only in his stand were up to the mark—namely, Wm. Skirving and Jas. Douglas. Mr. W. Rowan, 36, Manor Street, Clapham, was third, and Mr. A. Startup, 3, Stanley Road, Bromley, Kent, fourth.

Class D, single specimens of Scarlet Bizarres, Crimson Bizarres, Pink Bizarres, Purple Flakes, Scarlet Flakes, and Rose Flakes, five prizes in each class.—A very large number of blooms was shown in these classes. *Scarlet Bizarres*.—Mr. Douglas was first and fourth with Admiral Curzon, Mr. Turner second with Jas. Mackintosh, Mr. Headland third with Arthur Medhurst, and Mr. Headland fifth with Fred. *Crimson Bizarres*.—Mr. Douglas was first and second with Wm. Hewett, Mr. Headland third with Mrs. Whitbourn, Mr. Phillips fourth with Wm. Warhill, and Mr. Startup fifth with J. D. Hextall. *Pink Bizarres*.—Mr. Turner was first and third with H. K. Major, Mr. Douglas second with Isaac Scott, and fourth with Mrs. Gorton, and Mr. Headland fifth with Harrison Weir. *Purple Flakes*.—Mr. Douglas was first and second with his namesake, Mr. Turner third and fourth with Juno, and Mr. Rowan fifth with Jas. Douglas. In the *Scarlet Flakes* Mr. Douglas was first with Matador and second with Sportsman, Mr. Headland third with Sportsman, and Mr. Rowan fourth and fifth with Clipper. *Rose Flakes*.—Mr. Douglas was first and second with Sybil, Mr. Turner third and fifth with John Keat, and Mr. Phillips fourth with Thalia.

The prize for the premier Carnation in the Exhibition was awarded to Mr. C. Phillips, the variety being Tom Power, shown in his first prize stand of twelve in Class C. It was a large, well formed and very bright bloom, the colours being exceedingly clear.

PICOTEES.

Class E, twenty-four blooms, not less than twelve dissimilar varieties. Five prizes, 50s., 40s., 30s., 20s., 10s.—In this class, as in the corresponding one for Carnations, there were only two exhibitors, Messrs. Douglas and Turner. Their positions were, however, reversed, the Ilford exhibitor securing a ready victory. The following varieties were shown:—Back row—Her Majesty (2), very fine indeed; Liddington's Favourite (2), John Smith, and three seedlings. Middle row—Mrs. Sharpe (2), very bright and fresh; Miss Rudd, and five seedlings. Front row—Princess of Wales (2), Constance Heron, Muriel, Brunette, and three seedlings. Mr. Turner showed the following: Back row—Juliette (2), Liddington's Favourite, Rival Purple (2), Mrs. Nicholay, Her Majesty, and Princess Dagmar. Middle row—Robert Scott, Her Majesty, Mrs. Hanbury, Louisa, Dr. Abercrombie, Emily, Picco, and Miss Horner. Front row—Miss Horne, Picco, Emily, Lucy (2), Louisa, Mrs. Gibbons, and Dr.

Abercrombie. Mr. Douglas's many seedlings included several promising varieties, a heavy purple edge and light purple edge being both worthy of names.

Class F, twelve blooms, dissimilar; five prizes, 40s., 30s., 20s., 15s., 10s.—This class again was a repetition of the corresponding one for Carnations, Messrs. Douglas and Headland being the only exhibitors, and being placed first and second in the order their names are given. Mr. Douglas showed the following varieties: Her Majesty, Liddington's Favourite, Mrs. Sharpe, Brunette, Constance Heron, Princess of Wales, Miss Rudd, Muriel, and four seedlings. These were all exceedingly bright and fresh, and formed a collection of considerable merit. Mr. Headland showed Clara Penson, Triumph, Zerlina, Liddington's Favourite, Lady Holmesdale, Princess of Wales, Ethel, Her Majesty, Muriel, and several seedlings.

Class G, six blooms, dissimilar; five prizes.—This brought out three stands, Mr. C. Phillips winning the first prize with Juliette, Favourite, Mrs. Payne, Picco, Her Majesty, and Mrs. Dodwell. They were neat and fresh, but do not otherwise call for comment. Mr. Rowan followed with neat examples of Clara Penson, Master Norman, Emily, Her Majesty, Countess of Wilton, and Favourite. Mr. Startup was third.

Class H, single specimens.—Red, heavy-edged; red, light-edged; purple, heavy-edged; purple, light-edged; rose or scarlet, heavy-edged; rose or scarlet, light-edged, and yellow ground. One class, five prizes in each class. *Red, heavy-edge*.—Mr. Douglas was first and second with Princess of Wales, Mr. Headland third with Mrs. Robertson, and fourth with Brunette, and Mr. Phillips fifth with Mrs. Dodwell. *Red, light-edge*.—Mr. Douglas first with Violet Douglas, Mr. Turner second with Emily, Mr. Headland third with Emily and fourth with a seedling, and Mr. Startup fifth with Violet Douglas. The purple heavy-edge class found Mr. Douglas first and second with Muriel, Mr. Headland third with Muriel and fourth with Zerlina, and Mr. Turner fifth with Rival Purple. *Light-edged purple*.—Mr. Douglas was again first and second with seedlings, Mr. Headland third and fourth with Clara Penson, and Mr. Phillips fifth with Her Majesty. *Rose or scarlet, heavy-edge*.—Mr. Douglas was first with Constance Heron and second with Lady Holmesdale, Mr. Headland third and fourth with the same varieties, and Mr. Phillips fifth with Mrs. Payne. In the *light rose and scarlet-edges* Mr. Douglas was first with Liddington's Favourite and fourth with Miss Flowdy, Mr. Turner second with Lucy, and Mr. Phillips third and fifth with Liddington's Favourite. *Yellow grounds*.—Mr. Douglas was first and fourth with Agnes Chambers, Mr. Turner second and third with Annie Douglas, and Mr. Headland fifth with a seedling.

The premier Picotee in the Show was Muriel in Mr. Douglas's first-prize stand of twenty-four. It was a splendid bloom, the body colour being clear, the edge well defined, and the flower evenly formed.

MISCELLANEOUS: SELFS, FANCIES, OR YELLOW GROUNDS.

Class I, twenty-four blooms, not less than twelve dissimilar varieties; six prizes, 40s., 30s., 25s., 20s., 15s., 10s.—This class brought three exhibitors, and was a highly attractive one. A beautiful stand from Mr. Turner secured the first prize, the blooms being delightfully fresh. The following varieties were shown:—Back row: Annie Douglas (2), Mrs. Reynolds Hole, Almira, and Purple Emperor (2). Second row: Colonial Beauty, Agnes Chambers, Dorothy, Almira, Terra Cotta, and a seedling. Third row: Ellen Burrows, Mrs. Maclaren, Dorothy, Sybil, Agnes Chambers, and a seedling. Front row: Purple Emperor, The Bride (2), Amber, Terra Cotta, and Mrs. Maclaren. Mrs. Douglas was a capital second. Janira, Annie Douglas, Almira, Elaine, and others were very fine. The third prize was awarded to Mr. W. Toby, 3, St. Mark's Grove, Fulham Road, London, S.W., whose blooms were very neat, if somewhat small.

Class K, twelve blooms, dissimilar. Six prizes, 25s., 20s., 15s., 10s., 7s. 6d., 5s. Mr. Sanders, gardener to Vicountess Chewton, Bookham Lodge, Cobham, and Mr. W. Startup were the only exhibitors in this class. The former won easily, his opponent being very weak. Mr. Sanders showed the Crimson Clove, a sport from Jas. Douglas, very poor; A. Alegatière; Mary Morris, fair; Irma, Jean Sisley, Miss Jolliffe, very small, a sport from Mrs. Maclaren, Pride of Penshurst, and three seedlings.

Class L, yellow ground Picotees, not less than six to be dissimilar. Four prizes, 30s., 20s., 15s., 10s. Messrs. Turner and Douglas once more had the field to themselves in this class, the latter receiving the chief award. He exhibited a fine lot of blooms, Mr. Turner not being very far in the rear.

Class M, twelve specimens, dissimilar (from any or all of the classes, including Tree Carnations) in bloom, in pots not exceeding 8½ inches in diameter; three prizes. Three lots were staged in this class, Mr. Turner adding to his previous successes by securing the first prize. He showed fine healthy well flowered plants of Pride of Penshurst, Amber, Agnes Chambers, Mrs. Maclaren, Terra Cotta, Annie Douglas, Colonial Beauty, Prince of Orange, Howard's Yellow, Dorothy, Almira, and Purple Emperor. Mr. Douglas was a good second, and Mr. Headland a moderate third.

In the afternoon a lunch was held at the "Hotel Windsor," Mr. Thiselton Dyer presiding, with Mr. Shirley Hibberd in the vice-chair, and there was a good attendance of members of the Society.

PEACHES AND NECTARINES OUT OF DOORS.—These are rapidly recovering from the effects of cold winds and other checks. The fruit, however, is bound to be late in ripening, and unless there is plenty of sunshine in August much of the late growth will not ripen at all. The aim

therefore, should be to assist both as much as possible, and this can best be done by freely thinning the young growth, only laying in enough to furnish the trees with bearing wood next season. The growths being thus thinly trained will have the full benefit of sunshine and light, and the fruit will be similarly benefited. Those trees that have reached the top of the walls are apt to form most wood just under the coping, and the greater portion of this ought to be removed, only a few leaves being reserved beyond any fruit there may be. Light crops are the rule, but where there are exceptions continue to thin freely, as the fruit on overcropped trees is rarely of the best. Overcropping also materially shortens the lives of trees. One good fruit to every 8 square inches of tree surface is ample in the case of Peaches, but the Nectarines may be left rather more thickly. Remove all nails pressing against the fruit before the latter are spoilt.—W. I.

GARDENING LITERATURE PAST AND PRESENT.

[A paper by Mr. W. K. Woodcock, The Gardens, Oakbrook, Sheffield, read before the Walsley Amateur Floral and Horticultural Society, June 15th, 1883.]

It has been said that we may judge the moral and material character of a people by the nature of its literature; and if this be true of a nation so also I believe is it true of a profession, science, or art. Either of the latter possessing no literature of its own, or only such as is of a very poor character, is decided in an unsatisfactory condition. Gardening, however, is certainly not defective upon these grounds. Probably no other profession possesses a literature so ancient, so varied, or so generally useful, and which during the past twenty years has been so greatly extended and improved. Passing the scriptural references to gardens and the writings of the earliest authors we come to Pliny, a Roman author, who at the commencement of the Christian era, and at the time when the Roman Empire was in the zenith of its power and affluence wrote at great length concerning the gardens of the Romans. The wealthy nobles appear to have spent vast sums of money in the cultivation of flowers, and especially of Roses, which were used by them in such lavish profusion that as much as four million sesterces; or about £30,000, have been expended on them for a single banquet.

After the fall of the Roman Empire for a period of nearly five centuries there existed a state of semi-barbarity which is now commonly known as the "Dark Ages," and during which scarcely any books were written except upon religious matters, and these by the monks. The first book which appeared upon rural and gardening matters was by Crescenza in Italy early in the fifteenth century. None, however, appeared in Britain until that of Fitzherbert, which was published about the middle of the sixteenth century. The late Mr. G. W. Johnson in his "History of Gardening" tells us that the author of the first book on gardening in England was Watton de Honley in the reign of Edward III. Towards the end of the sixteenth century several authors of works on gardening and husbandry had appeared, among whom were Tusser, Mountain, Mascal, and Hyll, most of whom wrote on the subject partly from their own experience and partly by translating from Latin and Greek authors.

One of the earliest books of value was "The Gardeners' Labyrinth," published by Didymus Mountain in 1571. This book was professedly a compilation of extracts on gardening topics from various other works. A second part of this work was published in 1577, and other editions followed. During the seventeenth century garden literature grew apace. Many of the writers of this period were practical gardeners who wrote from their own experience. Amongst the principal names of writers were Plat, Lawson, Gardener, Standish, Parkinson, Plottes, Austin, Tradescant, Evelyn, Conley, Blake, Rea, Worledge, Meager, Temple, and others. Parkinson published a work entitled "Paradisus," or "Garden of Pleasant Flowers," in which he gives lists of flowers, fruits, and vegetables then cultivated. In his list of flowering plants he enumerates 137 sorts of Tulips, 95 of Narcissus and Daffodils, 50 Hyacinths, 31 Crocus, 73 Irises, 67 Anemones, 23 Ranunculuses, 9 Geraniums, 22 Auriculas, 21 Polyanthus and Cowslips, 52 Carnations and Gilliflowers, 20 Pinks, 24 Roses, and smaller numbers of varieties of other flowers. In 1653 appeared a treatise of fruit trees by Ralph Austen, which is said to be a good book and containing much sound information upon the subject. A book entitled "Adam out of Eden" was published by Adam Speed in 1659. In it he says, "There are those about London that make £200 an acre by gardening." Samuel Hartlib in his work a "Legacy of Husbandry," published in 1655, says Gardening is but of a few years' standing in England, and therefore is not well understood; and that a Surrey landlord feared the gardeners would spoil his ground by digging. Probably the best writer of the century was John Evelyn, F.R.S., a highly cultured and educated gentleman, born at Wotton in Surrey, and educated at Oxford. His principal works were "The French Gardener," a translation; "Fumifugium," or the inconvenience of the air and smoke of London. This work was dedicated to His Majesty Charles II., and published by his command; "Sylva, or a Discourse about Forest Trees," with an appendix on fruit trees; "Kalendarium Hortense," a monthly calendar of operations; "Terra," a discourse on the culture and improvement of the earth for vegetation and the propagation of plants; and "Pomona," a discourse on cider Apples. Very numerous were the writers on these topics in the next or eighteenth century, prominent amongst whom were London and Wise, Collins, Switzer, Fairchild, Miller, Abercrombie, Forsyth, Hitt, Wheeler, Repton, Whateley, and Nicol.

Probably the one whose works are most known and read even up to the present date is Abercrombie. He was a thoroughly practical

gardener, who having left his parents when some fifteen years of age, came to London, and after a time obtained employment in Kew Gardens, afterwards, at different periods, living as gardener with several noblemen, and following that, again, as a nurseryman at Hackney. He wrote fifteen or sixteen different books in his time, but undoubtedly the one which was most profitable to himself and to its readers was "Every Man His Own Gardener." I should not omit mention of the name of Mr. T. A. Knight, who was a very eminent pomologist and a voluminous writer. I was looking down a list the other day of the essays he had written, and found them to number no less than 107, chiefly relating to fruit culture. In the early portion of the present century garden literature made great strides, and very many new writers appeared, principal amongst whom were Mr. Joseph Sabine, Secretary to the Horticultural Society, who wrote numerous works on a great variety of subjects. William Salisbury wrote a work entitled "Hints to Proprietors of Orchards," which was much thought of. Henry Andrews, in 1802, published several useful works on "Heaths Illustrated," with coloured engravings. Walter Nicol also wrote about the same time a series of useful books, and he was followed closely by William Pontey, forester to the Duke of Bedford, who wrote "Rural Recreations, or the Gardener's Instructor," 1802; "The Forest Pruner," 1808; "The Profitable Planter," 1809; and the "Rural Improver," 1823; all practical works, which had a large circulation.

Sir Joseph Banks, President of the Royal Society, one of the most learned scientists our country has produced, about this time wrote a number of papers or pamphlets on gardening topics, all of them very valuable contributions, the principal and more important amongst them being, "An Attempt to Ascertain the Time when the Potato was First Introduced into this Country, with Some Account of the Hill Wheat in India," "Hints Respecting Inuring Tender Plants to Our Climate," "On Ripening the Second Crop of Figs that Grow on the New Shoots," and "Notes Relating to the First Appearance of the Aphis lanigera, or the Apple Tree Insect, in this Country." The greatest of all the gardening authors, however, who wrote in the early part of the present century, was undoubtedly Mr. J. C. Loudon, to whose valuable Encyclopædia on gardening I am indebted for many of the names and dates given in this paper. He was by profession a landscape gardener, and was born in Lanarkshire in 1782, commencing practice in his profession in 1803. In 1810 he was an extensive farmer in Oxfordshire and Middlesex. In 1813, 1814, and 1815 he had given up farming and was travelling on the Continent, and in 1820 he had settled down in Bayswater, London, practising occasionally his profession of landscapist, but occupying his time principally as an author. One of the most important and valuable contributions to gardening literature ever penned was his "Encyclopædia of Gardening," mentioned above. The first edition was published in 1822, and the fifth in 1827. It is an extraordinary book of nearly 1500 pages octavo, and very closely printed. It is written in a clear and pleasant style, is profusely illustrated with wood engravings, and deals in an exhaustive manner with every branch of gardening. He also published an Encyclopædia of Plants, and another of Agriculture, works similar in character and construction to the one on gardening. Another large work published by him was "Hortus Britannicus, a Catalogue of all the Plants Cultivated in, or Introduced to Britain," but the largest and most costly of all the works he undertook was "The Arboretum et Fruticetum Britannicum," generally called "The Arboretum," in eight octavo volumes, profusely illustrated. It is said to have cost £20,000 in bringing out. In addition to large sums he had paid in ready money during its progress to artists and others employed in its production, he found at its conclusion that he owed £10,000 to the printer, stationer, and wood engraver who had been employed on the work. He wrote several important works upon the theory and practice of landscape gardening, and also upon the construction of hot-houses. He was also Editor of "The Gardeners' Magazine," and "The Magazine of Natural History." His wife was a very accomplished and clever writer, and wrote numerous gardening works especially for ladies, one of which "The Ladies' Flower Garden," a beautifully illustrated work in six quarto volumes, is still in much request.

About 1820 the Transactions of the London Horticultural Society (which had been established in 1804, and received a Royal Charter in 1809) were annually published, and began to attract some notice on account of the excellence of some of the papers contained, and which proved a valuable contribution to garden literature. Other writers of this period were Griffin, Haynes, Hooker, Curling, Hogg, Lyon, Emmer-ton, Mean, and Brookshaw. Robert Sweet was also a writer of some valuable and useful works, as "The Botanical Cultivator" (1820), "The Hortus Britannicus" (1826), "The Geraniaceæ" (1830), "The Cistaceæ" (1830), "The British Flower Garden," "Flora Australasia" (1828), and "The Florists' Guide" (1832). Henry Phillips, who wrote between 1820 and 1833, also published numerous useful works. "The Floricultural Cabinet," a monthly illustrated gardening periodical, was commenced by Harrison in 1833 and was carried on for twenty-seven years. Loddiges, nurseryman of Hackney, whose nursery at that time occupied a leading position, began to publish "The Botanical Cabinet" (a very high class work) in 1817, and which stopped in 1833. It contains coloured plates of 2000 plants. "The Botanical Register," also a high class periodical, commenced in 1815, and stopped in 1847 with the thirty-third volume. The later volumes of this work were edited by Dr. Lindley. "The Horticultural Register," edited jointly by Paxton and Harrison, began in 1832, and extended to six volumes only, and "The Floricultural Cabinet," by Robert Marnock, commenced in 1836,

extended to the same number. "The Magazine of Botany," edited by Paxton, began in 1834, and had a fairly successful run extending to fifteen volumes. About this time George Glenny commenced "The Gardeners' Gazette" and "The Horticultural Journal." He also wrote numerous treatises and papers on florists' flowers.

"The Pomological Magazine" was commenced in 1827, is now sold as a complete work in three volumes, and contains coloured plates of many of our best fruits. "The Florist and Pomologist" was commenced by Edward Beck in 1848 and closed in 1882. It was for a long time a very popular illustrated monthly journal, chiefly valued for the excellent and faithful coloured representations it contained of fruits and flowers. In 1829 Mr. G. W. Johnson published a very valuable work, entitled "The History of Gardening," containing much information. McIntosh's "Practical Gardener," published in 1828, is another very useful work, as also is "The Book of the Garden," by the same author (1853). Paxton's "Gardeners' Dictionary," published about 1840, is a useful work, especially the revised edition of the same, with supplement, "The Cottage Gardeners' Dictionary," by Mr. George W. Johnson, first published about 1850, revised and re-issued subsequently, with a supplement including all the new plants and varieties to the end of the year 1880, by N. E. Brown, is a comprehensive and useful work, answering fully all the purposes required of a dictionary of this kind. Thompson's "Gardeners' Assistant," first published in 1859 by Robert Thompson of the Royal Horticultural Society's Gardens, Chiswick, is one of the most practical and reliable standard works ever written upon the subjects it treats upon, has been within the past few years revised and much extended by the late Mr. Thos. Moore of Chelsea Botanic Gardens. Other useful works published about the same dates are "The Culture of the Apple and Pear," by T. A. Knight; "The Miniature Fruit Garden," by Thos. Rivers; "The Gardeners' Calendar," by T. Mawe; "A Treatise on the Vine," by J. Meredith; and by George Glenny, "Handy Book on Gardening and Golden Rules for Gardeners."

I must now treat shortly upon works by authors now living, and which are very numerous and valuable. First, then, I would mention the "Fruit Manual," by Dr. Robert Hogg, which is undoubtedly the best work upon fruits ever written in the English language. Mr. Shirley Hibberd has been a very industrious and varied writer, and has contributed many useful books, foremost amongst which are Hibberd's "Amateur's Flower Garden," "Amateur's Greenhouse and Conservatory," "Amateur's Kitchen Garden," "Amateur's Rose Garden," "The Fern Garden," "Profitable Gardening," "The Town Garden," and "Water for Nothing." The Very Rev. Dean Hole has contributed two extremely interesting and practical works, entitled, "A Book about Roses: How to Grow and Show Them," and "The Six of Spades," both of which are very enjoyable reading. Mr. William Robinson is the author of numerous works, the best of which are "Alpine Flowers for English Gardens," "Mushroom Culture," and the "Wild Garden." To those interested in market gardening, a little work entitled "The London Market Garden," by C. W. Shaw, is full of useful information.

"Florists' Flowers," by J. Douglas, Great Gearies, Ilford, is the most practical work extant upon this subject, the writer being well known in the horticultural world as one of the most successful cultivators. A work has been issued by Messrs. Sutton & Son, of Reading, entitled, "The Culture of Vegetables and Flowers from Seeds and Roots," which is full of useful information. The same firm has just published what will doubtless prove a very successful little book of sixty-eight pages, entitled, "The Art of Preparing Vegetables for Table."

Mr. B. S. Williams, of the Victoria and Paradise Nurseries, Upper Holloway, London, is well known as being the author of several cheap and practical works; first amongst which is "The Orchid Grower's Manual," of which the sixth edition is now being sold, and which has grown in size and cost with each fresh edition issued. The first edition published in 1853 contained names and descriptions of 260 species and varieties of Orchids. The sixth edition contains names, &c., of 1470. The edition now being sold is a bulky volume of 650 pages, profusely illustrated. Other useful books by the same author are "Choice Stove and Greenhouse Flowering Plants," now in its third edition much enlarged; "Select Ferns and Lycopods, British and Exotic," "Choice Stove and Greenhouse Ornamental-leaved Plants," and last, but not least, the "Orchid Growers' Album," now, and since July, 1881, being published in monthly parts, and for the general excellence of character of which Mr. Williams has just had a gold medal awarded to him at Ghent, Belgium. Messrs. Sander of St. Albans, and Veitch of Chelsea, are each publishing expensive illustrated works on Orchids.

Mr. Lewis Castle, of the *Journal of Horticulture* is the author of several small and cheap, but very useful works to the gardener, principal amongst which are "Orchids, their Structure, History, and Culture," "Caetaceous Plants," and the "Chrysanthemum Annual." A remarkable feature of each is the large amount of information compressed into a small space. Mr. J. Wright, from the same office, has, as is well known, published a little work upon outdoor Mushroom culture, which has gone through four or five editions and become immensely popular. It is, in my opinion, a model of what such a work should be—clear, very concise, written in plain homely language, which none can fail to understand, and published at a price which makes it accessible to all. Coming under a like category is "Rose Growing for Beginners," written and published by my townsman, Mr. Duncan Gilmour, jun. I believe this little book, which is written much upon the same lines as is Wright's "Mushrooms," will have a large sale. Mr. Gilmour, like Dean Hole, has a happy knack of interspersing his more serious facts with quaint and raucy remarks, which tend to interest the

reader, and to keep him in a good humour alike with himself and with the author.

With regard to the gardening periodicals of the present day I may briefly state that while they are much more numerous than at any former period, the quality has, I believe, in no way deteriorated. A strong proof of the much greater interest taken in gardening pursuits now than formerly by amateur and cottage gardeners is in the fact that no less than four cheap weekly papers have, within about that number of years, sprung into existence. I would not wish to draw invidious comparisons as to the relative merits of these "papers," but must be content to say that as each has, and maintains, its own individuality of character, so each appeals to and obtains the patronage of a somewhat different class of readers.

After some remarks upon the trade catalogues of the present time Mr. Woodcock continued:—

I must now draw my paper to a conclusion, although I am most fully aware there are numbers of good authors and useful books which I have failed to notice. Sufficient, however, has been said, I hope, to prove that our craft has no need to be ashamed either as regards the quantity or quality of its literature. It is a very well known maxim that "demand creates supply," and as during late years the latter has so greatly increased, so also has the former. A spirit of research and inquiry is abroad. Everyone who wishes to keep abreast of the times now reads for himself, whereas within the comparatively short space over which my memory extends, good gardeners were to be met with in plenty who proudly averred that they never read gardening papers or books, and cared naught for that kind of teaching. The great change in this respect augurs well for the future of English gardening, which is, I believe, destined to take a much higher rank in British industries than it has as yet done. I believe that not only will gardens prosper, multiply and extend, and be rendered increasingly productive, but that as the cultivation on farms has professedly become unremunerative, gardening will be called upon more and more to play an important part in agriculture. It therefore behoves us each to avail ourselves of the opportunities at our command by attending such meetings as this, and by perusal of the best literature available, to fit ourselves, as far as we may, for whatever may be required of us.

HIGHGATE SHOW.

JULY 19TH.

THE Highgate Horticultural Society is doing good work in a large northern district of the metropolitan suburbs, and that the wealthy and influential residents in the neighbourhood fully appreciate this is shown by the ample support accorded. Last year the Committee succeeded in clearing off a deficit of £50, and this year a considerable reduction has been effected in the working expenses, which should have a correspondingly good effect in the balance at the end of the season. An active energetic Secretary, Mr. D. B. Crane, has now undertaken to pilot the Society, and there is every probability that the Show will grow in importance. The gardeners' classes constitute the principal portion of the Show, but more exhibitors are wanted, for three or four competitors now appear to share the prizes between them. In the cottagers' classes competition was, however, very keen, and the general quality of the exhibits most praiseworthy. The Baroness Burdett-Coutts and several other supporters of the Society give much encouragement to exhibitors in this department by means of special prizes for vegetables, fruit, and plants.

The President, Colonel Stedall, gave permission for the Show to be held in the Priory grounds, and upon the slope of a hill facing the Highgate Woods two large tents were erected, each of which was filled with competing exhibits and beautiful groups of plants from Mr. B. S. Williams, Upper Holloway, and Messrs. J. Cutbush & Sons, Highgate. Groups of plants arranged for effect were numerous, and some were tasteful, but too many examples of crowding were noticeable. Mr. J. Brittain, gardener to F. Reekitt, Esq., Caenwood Towers, and Mr. H. Eason, gardener to B. Noakes, Esq., Northhill, were respectively first and second in one class, while in another, for which the President provided the prizes, Mr. J. Brooks, gardener to W. Reynolds, Esq., The Grove, was the most successful exhibitor, followed by Messrs. Brittain and Eason. These three exhibitors won the chief prizes for stove and greenhouse plants, Orchids, Cookseombs, Balsams, Fuchsias, and Gloxinias, Mr. Brooks taking a large share of the honours. Mr. Brittain was first with six fine Ferns, and Mr. Eason with the same number of fine-foliage plants, Mr. Eason staging the best single specimen, a large example of *Maxillaria tenuifolia*, over 3 feet in diameter. Mr. G. Agate, gardener to H. Taylor, Esq., New Southgate, was first with well-grown Tuberous Begonias, and he gained a similar place with four Fuchsias, Mr. C. Shepherd, gardener to C. S. Duval, Esq., South Grove, taking the lead with Pelargoniums.

Cut flowers, stands of flowers, bouquets, &c., were fairly represented, Messrs. W. Brooks, W. Pink, Brittain, Agate, Calvert, and Shepherd securing the chief places. Fruit also from Messrs. Brittain, Agate, Calvert, Shepherd, and Brooks occupied a considerable space.

SUMMER-FLOWERING HEATHS.

ALL those having Eriacs standing in the open should endeavour to give them some protection from heavy and continual rains. More especially is this necessary where the plants are placed upon a wet or undrained bottom. Where shelter cannot be given in this temporary

situation let them be removed to frames or to their winter quarters; the former is preferable where the accommodation can be given. Here they should have a cool bottom to stand upon, for we have frequently seen Heaths, more especially the softer-growing kinds, go quite blind (that is, lose all the flower) through being suddenly removed from a cool standing place to an open greenhouse stage. Wherever they are placed, however, all the air possible must be given. Look carefully to the watering; see that none are only half watered, as this is a fertile source of mildew. Should this pest put in appearance dust the plants affected with sulphur; use it carefully, because it does not improve the appearance of the plants, and the less waste the better.

Some of the most distinct Heaths now flowering are the following, but several of these are too seldom seen in gardens at the present time though they can be still found in a few collections of hardwooded plants:—

Erica Uhria pilosa.—An extremely showy plant. Leaves arranged in threes, linear, and densely clothed with ciliated hairs, dark green. Flowers produced upon the apex of the small branches, mostly in couples; these are tubular and clavate, furnished with short hairs; colour deep reddish purple, green at the ends. Whole flower gummy.

E. nitida.—This is a perfect little gem, and should be more frequently found in amateurs' collections. Leaves obtuse, linear, spreading, arranged in threes and dark green. Flowers terminal, on short footstalks, in small umbels of three to six, globose, with a recurved limb, clear snow white.

E. metulæflora bicolor (fig. 9).—A charming free-flowering variety, free from the pest mildew, which is such a plague to the old metulæ-

FIG. 9.—ERICA METULÆFLORA BICOLOR.

flora. Leaves arranged in fours, linear, smooth, and light green. Flowers in terminal umbels of six to twelve, tubular, erect and oblong, soft rose colour, with a white neck and limb.

E. ornata.—This is a superb garden hybrid. Leaves arranged in fours, linear obtuse, hairy at the margins, and deep green. Flowers arranged in terminal whorls of six to twelve; they are large, tubular, with an inflated base, where the colour is soft rose or rosy carmine passing into white, and with a pale green band round the neck; segments of limb reflexed, white.

E. lustralis.—A slender-growing species, much branched. Leaves arranged in fours, linear obtuse, erect and dark green. Flowers globose, set upon long coloured footstalks, arranged in terminal umbels of six to twelve, and deep purple.

E. cubica minor.—A slender, dwarf, much-branched plant of great beauty. Branches arranged in whorls of three to five. Leaves linear obtuse, arranged in fours, shining dark green. Flowers in whorls near the ends of all the branches, bell-shaped, and deep reddish purple.

E. Aitoniana Turnbulli.—A slender-growing plant of great beauty. Leaves broadly linear, spreading, slightly recurved, dark green. Flowers an inch or more in length, in umbels of six to eight, tubular. Flowers white, changing to flesh colour or pink by exposure to the sun and air; segments of limb large and spreading, white.

E. infundibuliformis.—This is a dwarf-growing and very elegant species. Leaves arranged in fours, linear obtuse, smooth, erect, and dark green. Flowers in large terminal whorls upon all the branches; tubes long and slender, bright red; limb white; calyx imbricated, leafy.

E. effusa.—This together with *E. ornata* are garden hybrids which originated with the Messrs. Rollinson & Sons of Tooting, and they cannot be too highly recommended, for they are of good habit, large flowers, fine colours, very distinct and profuse bloomers. In this variety the leaves are dense, linear obtuse, dark green. Flowers produced in large terminal whorls of six to twelve, large, tubular, with an inflated base; colour wholly bright reddish crimson; segments of the limb reflexed, straw colour.

E. cerinthoides.—A strong and vigorous grower, although somewhat lax, and therefore requiring more support than many other kinds. Leaves in fours, linear oblong, acute, and profusely clothed with long light-coloured hairs; whorls terminal, many-flowered. Flowers tubular, with a slightly contracted neck, about an inch long, hairy, bright scarlet throughout. In the variety coronata the leaves are shorter and more erect, whilst the whorl of flowers is larger and spread evenly round, forming a corona or crown upon the ends of the shoots.—T.

LAMBTON CASTLE GARDENS.

A VISIT to the above is always pleasant and interesting under the guidance of Mr. Hunter. The beauties of Lambton Castle have so often been described in the pages of the Journal that reference here will be unnecessary at any length. Suffice it to say, it was just after a June shower we drove into the park, where all the beautiful contrasts of various shades of green foliage were seen to great advantage; the winding walks, well-kept drives, and the tortuous course of the river Wear, which is nearly navigable up to the castle, makes the pleasure greater after a few hours' escape from a begrimed and smoky town.

On the large terrace in front of the principal row of vineries is a series of beds which will have an imposing effect when the plants are fully developed. The groundwork is principally *Antennaria tomentosa*, *Lobelia Blue King*, *Alternantheras*, *Echeveria secunda glauca*, *Veronica repens*, &c. These are planted in a series of geometrical figures, which are bold, and will give a massive effect.

In the glass structures we were much struck with the marvellous crops of fruit in pots, especially of Pears. Amongst a dozen seedlings Mr. Hunter has received there is one that ripened its fruit on the 8th of June last. This was started in March with other varieties; the fruit is well coloured, good flavoured, in size about as large as an ordinary Beurré Diel, and resembles a Pitmaston Duchess. The name of the fruit is *Blanche Claude*. Mr. Hunter is much charmed with it, and in future it will no doubt form a very valuable acquisition for early work. Some little trees in 10 and 14-inch pots were carrying from one to three dozen fruits each; all the ordinary varieties are grown and each is found to do well, Pitmaston Duchess often attaining 20 ozs. each. Mr. Hunter's success is evidently due to being a very close observer of Nature. He argues, and with much logic, that when a tree bears a heavy crop one year it is generally not so good the second. This is always apparent under natural circumstances, but when artificial means are employed the practice of Mr. Hunter is still more effective, as by giving all the trees that bear well a year's rest they regain their lost vigour, and as there are some 500 trees in pots this can be easily carried out. Some grand Pinns were also good. Trees of Prince Englebert were positively laden from base to summit with fine fruits. Some of the varieties of Pears we omitted to mention often attain from 12 to 15 inches in circumference.

In the vineries we observed some very fine bunches of Black Hamburgh, 8 to 9 lbs. each, especially one Vine, which has always borne well. On each rod there averaged twenty-six bunches each. There were also grand bunches of Trebbiano and Calabrian Raisin all equally large. In the early house the bunches, 3 lbs. to 4 lbs. each, of Black Hamburgh, were well coloured and finished to perfection. The earliest house was started on the 1st December, Muscats were extremely fine, and so were Alicante. There is a new viney planted from last year's eyes, and the Vines have now made growths up to the top of the rafters, and there is no doubt that in future exhibitions the fruit from this viney will be admired. We observed some fine plants of Hydrangeas 6 and 7 feet high, trained in a pyramidal form, and very symmetrical; they were placed there to make their growth. They had just come from the conservatory, where they had flowered profusely, and are found most useful for decoration.

In the stoves we were struck with the profuseness of *Stephanotis*, which runs everywhere, and blooms at every joint; 1000 trusses have been cut in a month, and up to the 15th of June last, the time of our visit, 825 trusses had been cut for June. They are planted just between the pipes in the usual soil, and flower most admirably. Ixoras were also planted out in borders, and were equally as floriferous as the Gardenias. In the conservatory, the stove, or any available place, Eucharises are planted out and throwing up flowers freely, and, as Mr. Hunter points out, potting is saved, less water is required, and drying is not needed, which are all great savings in a large establishment where so much is required, but there are also some very fine plants in pots which are used for conservatory decoration.

In the warm conservatory is *Phoenix dactylifera* in flower. Last year this plant was much used for table decoration, where the colour of the fruit is found to be attractive. This is advantageous for the winter months, while many like and enjoy the fruit. *Cycas revoluta* is also used in the same way. Mr. Hunter has a great number of seedling Crotons which seem to possess considerable merit. Many of them are extremely fastigiated and diversified in leaf and colour. There are a

half dozen fine specimens, and by autumn they will have attained a glorious colour. Plants of *Crotons Andeanus* and *mutabilis* averaged about 6 to 7 each high, and were marvellously clean. They are syringed twice a week with 3 gallons of water containing half a wineglassful of petroleum, and neither scale, thrips, nor mealy bug was visible. —E. COWAN.

DEGENERATION OF FRUIT AND VEGETABLES.

[A paper read before the Massachusetts Horticultural Society by Mr. O. B. Badwen, Worcester, U.S.A.]

THE term degeneration, in its larger definition, when used with reference to fruits and vegetables, is generally understood to apply to those which, having been cultivated for a longer or shorter period of time, and having had their day and generation, seem to have run out and no longer retain their original characteristics. Nature seems to have endowed every plant known in the vegetable kingdom with an allotted term or definite period of life; especially when growing in its native climate and soil, and surrounded by conditions not unfavourable to its life, growth, maturity, and method of reproduction. In attempting the inquiry into the period of longevity of fruit-bearing trees, and fruits growing thereon, together with the fruit-bearing bushes, shrubs, canes and Vines, I find but few data relating to the subject, and must rely largely upon my personal observation and experience, and my own recollections of the past fifty years. All the fruit-bearing plants are naturally grown from seed planted by the intricate processes of Nature. The seed contains all inherent natural forces requisite for reproducing its kind, and the seedling plant seems endowed with the vitality and functions requisite for and pertaining to its growth, maturity, and reproduction during its destined period of life. The time allotted for the continuance of plant life seems as variable as the external features of the plant itself. Whilst the limit of human life may be three score years and ten, in tree or plant life we know it may be many times three score years. The average lifetime of the lower animals is well known; but comparatively little is known of the life of fruit-bearing trees, and even less regarding the time our popular varieties of fruits will continue to be produced in perfection under the prolonged cultivation of the sagacious horticulturist.

The causes, natural and artificial, of fruits degenerating and becoming unworthy of cultivation are but imperfectly understood; as the many sorts seem to be subjected to many varying conditions. In the case of each we have to consider its natural hardiness and longevity, the influence of soil and climate, the stimulating effects of liberal cultivation, the mysterious influences of engrafting, both as to stock and scion. All these and similar questions underlying the subject are so clouded and obscure that we can neither fully explain nor comprehend them. Nevertheless there are some facts that seem to throw a little light upon the subject. While perhaps it is utterly impossible to fully verify the causes that seem to augment the degenerating tendencies in fruits, the facts we rely upon seem apparent, and although the evidence by which we trace the causes seems partially circumstantial, yet it is unequivocal, so far as it goes, and cannot well be set aside in communities where cultivation has been pursued for fifty years or more by "the art which doth mend Nature."

The Pear trees grown from seeds which were planted by the earlier settlers of America were of a robust habit of growth, attaining large size and great age, and have outlived many generations of men; and of those known to have borne fruit as early as 1663 some are still alive. The Pear tree is indigenous in sections of the northern temperate zone, flourishing as far north as the fifty-seventh degree of latitude, and is grown in this country from the British Provinces to Mexico. In acclimating and growing the Pear in a warmer climate, its primitive habit of long life seems to be partly lost. Growers long since abandoned planting the seeds from the original fruit, using instead the seeds of the engrafted sorts, which are of a more tender habit; by this practice breeding into the Pear tree an inherent tendency to shortness of life. The continued process of engrafting and forcing by high cultivation and also growing in an impoverished soil—each and all may exert some influence in the direction of degeneracy; and it is certainly evident that the trees are everywhere tending to earlier fruitage and shorter life.

The almost universal practice of propagating desirable sorts by engrafting or budding has undoubtedly the effect of gradually, but surely, working a serious injury to some fruit-bearing trees. The tendency of continuously planting the seeds of improved sorts is very much the same as what is called in cattlemen's parlance "in-and-in breeding," which if long continued in a given line is a sure and constant cause of degeneration. Now, if the tree from any cause is losing its natural stamina and force, or becomes defective or diseased, the weakening of its natural functions very soon becomes manifest in the fruit. The St. Michael, in its day the glory of the Pears, has now become wholly unworthy of cultivation. Sometimes it seems to recuperate in new countries and thrives for a time in a virgin soil, but soon relapses into its now normal condition. The Flemish Beauty affords another illustration of degenerating tendency. It was first brought into notice in 1834, and promised well for many years, but has now become unworthy of continued cultivation.

In the catalogue of trees grown in the nursery of the late William Kenrick in the year 1838 (he being then one of the prominent nurserymen in Massachusetts), I find, in the class termed "Old Pears," twelve sorts of which not one has been shown on this Society's tables for years. In class second, termed "New Pears," I find eighty-seven; of which seventeen varieties only are seen at our exhibitions, and but four

of these are generally approved—viz., the Bartlett, Bosc, Seckel, and Angoulême, and the rest are only occasionally shown. In the list of new Pears received in this country from Europe in the years 1834 to 1836, consisting of 140 varieties, which have been tried by our cultivators, and (most of them) shown on our tables within the past forty years, I find but two that are now considered worthy of cultivation; and Mr. Kenrick mentions 100 other sorts received but not tried.

In the catalogue of the late William R. Prince of Flushing, N.Y., for the year 1839, designating by name 367 varieties, I find but thirteen varieties that are seen on our tables. Then we are made aware of the very numerous sorts of Pears which were being brought into notice forty or fifty years ago—more than 350 varieties, out of which less than twenty are on our premium list for the present year, and the other 330 have practically gone out of cultivation. In the meantime very many more sorts have been introduced, in large part seedlings of American origin, and out of this vast number twenty-five varieties would be quite as many as are worthy of the Society's approval and encouragement.

Now it would be unfair to state that this very large number found unworthy of cultivation have degenerated, doubtless many causes contributed to influence their rejection. Some were found poor growers, the fruit in many cases lacked the qualities essential in good Pears; some seemed naturally predisposed to blight and other disease, and many seemed unsuited to the soil and climate.

But it appears, although difficult to prove, in the case of some sorts once highly esteemed for general cultivation, but now become degenerate, that the tree has already lived the time allotted by Nature, and its production of fruit in its enfeebled condition is prolonged only by nursing, or by engrafting on other and vigorous stocks. This suggestion opens quite another phase of the question—viz., How much can fruitage be prolonged by the process of engrafting or budding?

There was formerly an adage, "He who plants Pears plants for his heirs," while now he who plants Pears gathers a crop in a few years; and the trees mature, bear fruit, and die, even before the heirs are born. But it can easily be demonstrated that the natural lives of the original sorts of Pear trees have been longer than the joint or aggregate lives of several generations of men; and also that the product of fruit from an original stock can be artificially prolonged by engrafting to an undetermined extent.

The Apple trees that were grown from seed planted by the early settlers, and cultivated as early as 1663, in many instances proved long lived, some reaching the age of 200 or more years; these trees attained great size, and bore immense crops of natural fruit. I know of Apple trees still bearing good crops that have every appearance of being 150 years old; and I know of engrafted Apple trees more than sixty years old that are still productive and unimpaired. On the other hand I can point to an orchard which was set forty-five years ago, and has received high cultivation, that has already become old and worthless, having no force to make healthy wood or bear fruit. And I read that Apple orchards in some of the north-western States do not average more than twenty years in bearing. The process of degeneration or decay of the Apple seems to be less rapid than that of the Pear; out of sixty varieties, mostly of American origin, grown fifty years ago, more than forty are now grown and esteemed. In fact I can recall but few sorts once extensively grown that are proving worthless; and in reviewing the history of the Apple it must be admitted that it is not only the most valuable fruit in this section of the country, but also long lived, and is manifesting at present but few signs of decay. The Early Harvest and the Newtown Pippin seem to be on the wane, and a few more are tending in that direction. On the other hand the Rhode Island Greening, known in cultivation for 150 years, is seemingly as good as ever, both in tree and fruit, and promises to last for a long time. The Costard, one of the oldest Apples grown in England, was recorded in the thirteenth century.

Among the fruits that were formerly plentiful the Peach is the best demonstration of degenerating tendencies; it is the one that seems least able to withstand the departure from its normal condition occasioned by engrafting and modern usage, and the effects of climate. In former years the Peach was grown from the stone exclusively, and grafting was not practised. Then the trees not only escaped disease but withstood the vicissitudes of the climate unimpaired and produced abundant crops, the ground under them, within the memory of many now present, used to be literally covered with luscious fruit at the season of ripening; while the life of a Peach tree often extended to fifty years, and by cutting back to the ground and allowing it to sprout from the root, to even a much longer period.

But when the nurseryman commenced to prolong the existence of improved varieties of fruit by budding not many years elapsed before the loss of original stamina and hardiness became apparent. Before long (in 1818) that destructive disease known as the "yellows" crept in. This was first noticed or described in print by a nurseryman in 1823; it was very soon ascertained to be contagious, and that the disease had come to stay. In the northern sections of the country Peach growing, always precarious, now seems utterly ruined.

The question of actual degeneration seems fairly settled in the Peach tree, and the fruit follows the tree, and varieties have become lost. Now the question naturally arises, Can the Peach be restored? Evidently not until the budded trees are thoroughly extirpated, root and branch. We must resort to the custom of our ancestors, of growing trees from seeds, and these seeds should be procured from sources where disease is unknown in any form. Then we may hope with reasonable certainty for another period of healthy Peach trees and luscious fruit.

Many sorts of Peaches reproduce their like from the seed. These fixed strains should be encouraged, and painstaking cultivators might impregnate the blossoms of such with pollen of good sorts. By saving the stones of fruit thus produced they would materially increase their chances of success in producing new and desirable varieties.

(To be continued.)

LEE, BLACKHEATH, AND LEWISHAM SHOW.

THE twenty-first annual Exhibition of fruit, flowers, and vegetables was held in a field adjoining the gardens of Mrs. Penn, The Cedars, Lee. The Exhibition was one of the best held in the suburbs this season, and the Committee, with the energetic Secretary (Mr. C. Helmer) may be congratulated on its success. A serious drawback, however, was the most unpropitious state of the weather on both days, the rain rendering the ground extremely wet. As a consequence of this the funds of the Society will suffer considerably, but no doubt in the future, as in the past, the members will give their ungrudging support, and thus help it out of its present dilemma.

The exhibits were of the most praiseworthy character. The plants were quite up to the average of former years, and the fruit and vegetables, also cut Roses, better than have ever been shown at previous exhibitions.

Special prizes were offered by the tradesmen and leading residents of Lee. The first class for a collection of vegetables and salad combined, open to gentlemen's gardeners and amateurs, had four competitors. The collection of Mr. F. Fox, gardener to Mrs. Penn, contained an excellent assortment and nicely arranged lot of vegetables, which gained first without any difficulty. Mr. Nunn, gardener to — Soames, Esq., came in second with a good lot, and Mr. W. Jeffery's third was very creditable. The prizes in this case were offered by Messrs. Maller and Son, Keech, and Nettlefold. In the second class, for two more prizes offered by the tradesmen of Lee for a collection of twenty-four miscellaneous plants, pots not to exceed 9 inches, Mr. J. Hudd, gardener to F. W. Prior, Esq., was first with a nice group; Mr. S. Reece, gardener to R. Whyte, Esq., second; and Mr. W. Garland third. For a similar number of prizes offered by the tradesmen of Blackheath for a group of plants arranged for decorative effect, space not to exceed 40 superficial feet, Mr. J. Barker secured first with a charming and most effectively arranged group, the plants employed being light and graceful, and flower and foliage in proper proportion to each other. Mr. J. Hudd was second, but his arrangement, though good, was too flat and set; third, Mr. Nunn. There were only two competitors in the class for a collection of twelve plants in flower, the first prize going to Mr. W. Jeffery, gardener to J. Young, Esq., and the second to Mr. H. Martin, gardener to A. English, Esq. Three prizes offered by Messrs. John Laing & Sons for six distinct named tuberous Begonias created a sharp competition. The first prize was well won by Mr. R. Sholdice, gardener to R. P. Barrow, Esq., with exceedingly well grown and flowered plants; Mr. C. Helmer, the Secretary, coming in a close second, and Mr. W. Garland third.

The class for nine cut Roses had six competitors. The first place was easily gained, however, by P. Burnand, Esq., Reigate, with grand blooms of Ulrich Brunner, Madame Gabriel Luizet, François Michelin, Louis Van Houtte, Marie Baumann, Prince Arthur, John Hopper, Baroness Rothschild, &c.; and the second, by Mr. G. Barker, were also highly creditable, which would have run rather close for first had the blooms been arranged to better advantage. For four Fuchsias, distinct, Mr. C. Saville, gardener to J. W. Wilson, Esq., was first with finely grown and well flowered examples. Mr. Clark, gardener to H. Wolfram, Esq., second, and Mr. T. Dobson, third. Messrs. Merryweather & Sons offered as a first prize for a collection of salad and vegetables in twelve varieties a length of their new sphincter hose grip flexible indiarubber armoured garden hose, this being won by Mr. C. Nunn, and a second prize in books by Mr. W. Garland.

Messrs. James Carter & Co. also offered a special prize for the best six varieties of vegetables, but there was only one competitor, Mr. W. Burgess. This exhibit, however, was a highly creditable one for an amateur, and he was accordingly awarded a first. We now come to the last of the specials, this being a series of three prizes offered by R. Whyte, Esq., for a table of plants. The first was deservedly awarded to Mr. F. Fox, gardener to Mrs. Penn, for good plants. Mr. Clark second, and Mr. Jeffery third.

In the gentlemen's gardeners' classes for six stove or greenhouse plants in flower, other than Orchids, there were but two competitors. As usual, Mr. Reece, gardener to R. Whyte, Esq., carried off the first prize with very fine examples of *Allamanda grandiflora*, *Rhynchospermum jasmoides*, *Erica Parmentieri rosea*, &c.; Mr. J. Hudd, gardener to F. W. Prior, Esq., being second with creditable specimens, including a well grown and flowered example of *Diplaeus glutinosus*.

In the class for six plants of ornamental foliage, Mr. Reece again secured first place with admirably grown specimens of *Philotanium Lindenii*, *Alocasia metallica*, *Croton Warreni*, *Livistonia rotundifolia*, &c.; Mr. Hudd coming in second with highly creditable examples of *Anthurium Warocqueanum* and *Cycas revoluta*; Mr. Lambert, gardener to H. W. Segeleke, Esq., securing a third. For six show Pelargoniums Mr. Reece was first, having grand plants of *La Pureté* and *Hereules*; Mr. H. Martin second, and Mr. G. Barker third. For six double flowering Zonals Mr. H. Martin first, and Mr. Clark second. The class for six exotic Ferns was warmly contested. The chief honours fell to Mr. Hudd, who had grand specimens of *Davallia Mooreana*, *Microlepia hirta*

eristata, and *Dicksonia antarctica* in his collection. Mr. S. Reece, who in former years has occupied the highest winning position in this class, had to be content with second place this year. This exhibitor had a magnificent specimen of *Davallia fijiensis* in his group, probably the finest in the country, but his other plants lacked size and finish as compared with other years. The third prize went to Mr. R. Sholdice. Mr. J. Lambert scored a first for four *Lycopodiums*, and Mr. W. Jeffery a second; whilst for six *Caladiums* Mr. H. Martin was first with fine well coloured plants of Dr. Lindley, Albert Edward, Louis Duplessus and Leplay. Mr. T. Aley a good second, and Mr. W. Jeffery third. Mr. S. Reece was the only exhibitor in the class for six Heaths, and he deservedly received the award of a first. The *Fuchsia* classes were well contested, Mr. Dobson, gardener to F. T. Preston, Esq., being first for six pyramids; Mr. W. Jeffery second, and Mr. H. Martin third; the latter also being first for a couple of standards, and Mr. J. Hudd second. *Gloxinias* were grand, especially those shown in the class for six by Mr. R. Sholdice, one of which was carrying upwards of forty blooms. These of course gained the first award, and they were closely followed by Mr. G. Barker's, which came in second. Mr. S. Reece was first for a specimen plant in flower with *Dipladenia profusa*; Mr. Hudd second with *Allamanda Schottii*, and Mr. W. Garland third. For the best specimen out of flower, first, Mr. Lambert; second, Mr. W. Segrott; third, Mr. Hudd. Mr. Reece was first for six *Dracaenas*, his examples of *pulcherrima*, *amabilis*, *Lindenii*, *Baptisti*, and *hybrida* being beautifully coloured. Mr. Clark came in second, and Mr. W. Jeffery third. Only one competitor entered the list for a specimen show *Pelargonium*, and this was Mr. Jeffery, to whom a first was awarded.

In the gentlemen's gardeners' and amateurs' classes, for four plants of ornamental foliage Mr. W. Jeffery was first with *Croton Youngii*, *Pandanus Veitchii*, *Croton Veitchii*, and *Dracaena Baptisti*; and Mr. C. Nunn second, there being only two competitors. Orchids were not represented very strongly. Mr. J. Hudd was the only exhibitor in the class for four, his plants comprising *Cattleya Mossiae*, *Odontoglossum grande*, *Aerides virens*, and *Oncidium crispum*, all well grown and flowered. For a specimen Orchid in flower Mr. Hood, gardener to M. N. Buttanshaw, Esq., was first with a well flowered and fairly good type of *Odontoglossum vexillarium*; Mr. Hudd second with *Dendrobium Pierardi*; and Mr. Jeffery third with *Aerides odorata*. For four ornamental foliaged Begonias Mr. Lambert was first, there being no other competitors, the same exhibitor again coming in first for four Tuberous Begonias, Mr. C. Helmer second, and Mr. R. Sholdice third. Mr. F. Dobson was first for four *Gloxinias*, Mr. Helmer second, and Mr. T. Aley third. In the class for four exotic Ferns Mr. J. Lambert received the premier award for well grown plants of *Adiantum farleyense*, *Asplenium nidus avis*, and *Davallia Mooreana*, Mr. Jeffery receiving the second, and Mr. G. Baker the third. There was only exhibitor in the class for six hardy Ferns, consequently only one award was made, a first to Mr. R. Sholdice. The class for four *Dracaenas* had only two competitors, these being Mr. Hudd and Mr. Lambert, who were placed first and second respectively. For six Palms Mr. Reece was first, and Mr. Jeffery second. For three plants for dinner table Mr. J. Lambert was first, Mr. Clarke second, Mr. Hudd third, and Mr. W. Garland fourth; and for a single plant, first Mr. Lambert, second Mr. Hudd. Mr. W. Jeffery was the only exhibitor of four show *Pelargoniums*, and was placed first, receiving a similar award also for four Zonals, Mr. Hudd being second. Mr. Jeffery also secured first for four double flowering Zonals. Mr. S. Reece again came forward as the winner of the premier prize in the class for six exotic Ferns, and Mr. Clark and Mr. C. Nunn are the respective chief winners in the class for six *Caladiums*, and Messrs. J. Lambert and H. Martin the *Petunia* classes.

Amongst the cut flowers Roses formed a prominent feature of the Show. In the class for forty-eight, Mr. A. Harris of Eltham was first, and Mr. F. Fox, gardener to Mrs. Penn, second, the blooms in both cases being above the average in size and quality as generally exhibited at this Show. In the twenty-four class there was a brisk competition. The first was carried off by P. Burnand, Esq., Reigate, with even, well-finished blooms; Mr. G. Barker coming a close second, and Mr. J. Bateman third. The twelves were also shown in good form, the stand of Mr. G. Barker, which gained the first prize, containing some exceptionally good blooms of *Countess of Oxford*, *Marie Baumann*, and one or two others; Mr. Burnand came second, and Mr. J. Bateman third. Mr. J. Hudd was first for a box or stand of cut flowers, and Mr. J. Garland second. In the class for a hand bouquet, Messrs. G. Shrubbs and E. M. Kenward were the respective winners.

There was a goodly quantity of fruit exhibited compared with former years. Mr. Jeffery was first for a collection of six dishes. In the class for three bunches of black Grapes, Mr. Payne was first, Mr. J. Hudd second, and Mr. Jeffery third. For three white bunches, first, Mr. Payne; second, Mr. Hudd; and third, Mr. Jeffery. Mr. Payne was also first for a single bunch of white and black, Mr. Hudd being second. Mr. W. Garland was first for a dish of *Bellegarde* Peaches and for a dish of Nectarines. For a Melon, Mr. C. Saville was first; and for a dish of Strawberries, Mr. G. Shrubbs was first, and Mr. Fox second. Messrs. W. Segrott, A. E. Martin, and G. Shrubbs were the chief prizetakers in the classes for salads and Cucumbers.

Mr. W. Garland and G. Shrubbs carried off the leading prizes for collections of fruit, and Messrs. Stockwell, Fox, Nunn, Burgess, and E. Martin in the vegetable classes.

Some very effective arrangements displaying the highest skill and taste on the part of the lady exhibitors were shown in these classes. The winning stand of cut flowers by Miss Bidwell was exceedingly

pretty, being composed of light sprays of Maidenhair Fern and blooms of Spanish Iris, the whole looking charmingly beautiful and chaste. Miss Dent was second, but hers was not nearly so pretty as the last named. Only one bouquet was shown, but this was well arranged and composed of choice flowers. Miss E. Helmer was the winner of a first prize for this. Three lots of buttonholes were shown, Miss Helmer being first and Miss Dent second. Miss Bidwell was first for the best arranged basket of flowers, and Miss E. M. Kenward second.

There were in addition to the foregoing a number of classes set apart for cottagers and amateurs, and these were all fairly well contested. Groups of plants were contributed by Messrs. J. Laing & Sons, B. Maller and Sons, and others, and wreaths and crosses by W. Garton, nurseryman, Blackheath. Messrs. Laing also showed a collection of cut Roses not for competition.

KITCHEN GARDEN.

THE WEATHER AND VEGETABLES.—The present season is too wet and sunless for most vegetables. Turnips have formed an unusual amount of top growth, but the roots are small. Peas are tall and luxuriant, but they do not fill well. Broad Beans are failing to produce many flowers. Runner Beans are late—we shall not gather any during July; but the dwarfs in the open are ready, thus showing the advantage of sowing the latter as well as the former. The Potato crop we are most concerned about; last year diseased tubers were quite exceptional; the year before that, and indeed for several years previous, the crops were wonderfully good, but a dripping July almost invariably produces much disease.

MAGGOTS.—Last year, although hot and dry, vegetables were free from maggots at their roots. Onions, Carrots, and other crops were never touched, but we fear they are not going to enjoy the same immunity this year, as we know of several instances where the maggots are attacking the Carrots and Onions. This is bad news, and efforts must be made at once to check them. A good sprinkling of soot, gas lime, or salt should be strewn amongst the plants, to be washed down with the rain, and where it is too late to save the crops sow a ain. Carrots of the Horn type if sown at once will gain full size before November. There is no use in being disheartened by a failure this year. Sow again and persevere, but before doing so take the precaution to dress the ground well with some of the ingredients named above.

COLEWORTS.—Some imagine this to be a very distinct vegetable, but it is really only a form of Cabbage, and Cabbage planted in July may often be taken for Coleworts in November, but they are not so hardy as the Rosette Colewort, and this is the variety that should be grown. To be of any use they must be planted out before July is over. They do not grow to a large size, and may be planted at a distance of 15 inches apart. They are equally as hardy, and more delicate on the table than Savoy in winter.

CELERY.—We cultivated a quarter of the American White Plume Celery the first season it was introduced, and have done so ever since; but we have more than usual this year, as it is useful in the autumn. Our earliest plants are 2 feet high, very white; in fact, in good condition for present use or showing. But this novelty has not induced us to give up the ordinary Celery, and no one should do this, as we must all depend upon these for winter and spring use. The earliest rows in the trenches may be earthed a little. Break off the small side leaves before commencing this operation. Dust the stems with soot, and then break the soil well up along each side of the trench, and put it up to the stems with the hands. This is not such a quick way of earthing as pushing the soil in and about them with the spade, but it is the best way to prevent the plants being spoiled by the soil falling into their centres. More late plants may still be placed out, and if some are planted on the level ground they will be useful for flavouring.

OPEN AIR TOMATOES.—These are now receiving a great deal of attention, but it is not a good season for succeeding thoroughly with them, as they delight in plenty of sunshine. The only way to secure a crop this year is to keep them very bare of foliage, and expose the fruit as much as possible, only one or two main stems being taken up from each plant, and some of the largest of the leaves on these may be cut off. Eight, ten, or a dozen fruits may form as a cluster, but if the smallest of these are removed and only three or four left on each cluster they will have a much better chance of gaining a good size and ripening. Do not overwater them, and avoid giving them liquid, as under present circumstances this would only tend to make them form a superabundance of foliage. Some time ago we plunged a quantity of plants in 6-inch pots along the bottom of a south wall, and these are bearing much better than those which were planted out.

CAPSICUMS AND EGG PLANTS.—These may both be grown together, but neither will succeed in the open; and if warmer quarters than a cold frame can be given them they will be benefited by it. Do not overpot them. Let the plants become root-bound if plenty of fruit is

desired. Syringe frequently to keep them free from insects, and close early in the afternoon to induce the fruit to ripen.

CABBAGES FOR EARLY SPRING.—It is now well known that Cabbages are more valuable and acceptable in early spring than at any other time. They can never be too early or too good, and the present is the best of all times to sow the seed. We always sow during the last week in July. Good varieties are numerous. Form a bed large enough to raise sufficient plants to meet the demands. Make the soil moderately rich, sow the seed broadcast, and cover it with the surrounding soil to the depth of half an inch. See that the young plants are not destroyed by birds or insects, and keep them free from weeds.

FRUIT FORCING.

VINES.—Earliest House.—The Vines now require a dry atmosphere to thoroughly ripen the wood, but it will not be necessary to employ artificial heat to secure the requisite warmth. Free ventilation will be all that is in most cases necessary, but where the Vines are vigorous and have a tendency to strong growth in the laterals the house may be kept at from 80° to 85° by day by reducing the ventilation, yet not entirely closing the house, and throw the ventilators fully open at night. Syringe occasionally to cleanse the foliage of red spider. The border must not be allowed to become parchingly dry; a mulching of any spent litter will prevent evaporation and the surface cracking. Cover the outside border, if the weather be very wet, with lights to throw off the rain. Keep all laterals and late growths well in hand, and they must not in any case be allowed to interfere with the access of light and air to the principal leaves, and they must not be reduced to such an extent as to cause buds below the first stopping to start; therefore, lateral reduction must be practised with judgment. In the case of weakly Vines an extension of the laterals will tend to promote an increased root action, and an application of liquid manure contribute to the plumping of the buds. Such Vines should not be pruned too closely, allowing the growth to extend as far as circumstances allow.

Vines in Pots.—Those for next season's fruiting will have completed their growth, and cannot have too much light. Give only enough water to keep the leaves fresh; but if the soil is too dry it will induce premature ripening, and excess of water will unduly prolong the growth.

Young Vines of the Current Year's Planting.—Allow them to make all the growth practicable consistent with the exposure of the foliage to light. Nothing is gained by crowding the foliage of young Vines, not even those that have to be cut back to three or four eyes at the winter pruning, whilst any that are to afford fruit next season should have the laterals rather closely pinched back to a length of 6 or 7 feet of the canes, the canes being stopped at that length, above which the laterals may have more latitude, as they will aid in the production of roots.

Midseason Houses.—The Grapes in these are commencing to colour. The inside border should have a thorough soaking with liquid manure or a surface dressing of some approved fertiliser applied, and washed in with rain or pond water. If well water be used it should be brought to a temperature equal to the mean of the house before being applied. With a mulching 2 to 3 inches thick of some short but only partially decayed material, as stable litter freed of the strawy portions, the watering will hardly require to be repeated, but it is necessary to distinguish between varieties that ripen in a short time and those that require nearly double the period. Black Hamburgs and similar sorts ripen in much less time than Muscats, and those do not require so long a time as the thick-skinned varieties, therefore the waterings must be continued longer for the latter than the former, and so as to suit the requirements of each. Moderate air moisture is necessary for preserving the health of the foliage and to ensure the swelling of the crop, which is considerable as regards the size of the berries after they commence ripening. Admit air freely, a little constantly so as to insure a circulation constantly, increasing it early so as to prevent the air moisture being condensed on the berries. Maintain a night temperature of 70°, 5° more by day, with 80° to 85° from sun heat. Muscats should have a night temperature of 70° to 75°, and 80° to 85° or 90° by day. Vines that are carrying heavy crops require more time, allowing the temperature to fall to 65° or even 60° to rest the Vines, and they should be encouraged to extend, rather than be checked by closely pinching the laterals. Varieties that are liable to crack must have a heavier mulching of dry material, and great care be taken to prevent moisture being deposited on the berries, admitting air freely, and keeping a gentle warmth in the pipes.

Houses of Ripe Grapes.—White Grapes assume more colour by exposure to light, and they are more subject to spot and decay through moisture in the atmosphere. During moist weather, therefore, a constant circulation of air must be kept to prevent moisture condensing, which will necessitate gentle heat in the pipes. Black Grapes will not keep colour long unless the foliage is good, nor plump unless moderate air moisture is present. A double thickness of herring nets placed over the roof lights will assist in preserving the colour and bloom. Afford sufficient moisture at the roots to maintain the foliage in good condition. If the necessity for water arises (and it is no use waiting until the berries shrivel, for no amount of water afterwards will restore them to plumpness) afford it in the early part of a fine day, and afford air freely so as to dissipate moisture from the surface before the necessity arises of withdrawing it for the day. A temperature of 60° will be ample at night and 5° more by day artificially.

Houses of Late Hamburgs.—These will not require artificial heat unless the weather be unusually cold, as has been lately, necessitating

fire heat in houses to which it is not usual to apply it in July. A temperature of 60° to 65° should be maintained at night, and 70° to 75° by day, in order to a satisfactory swelling of the crop. Inside borders must have a thorough supply of water or liquid manure as necessary, and to encourage surface roots a mulching of some short but not very decayed manure should be given, and a few fresh horse droppings sprinkled on the surface occasionally will afford ammonia vapour, contributing to the health of the Vines. Close early, well damping available surfaces at the time, but the temperature after closing ought not to exceed 90°. Ventilate between 70° and 75°, and keep through the day from sun heat at 80° to 85°. Leave a little ventilation at the top of the house at night, increasing it early so as to dissipate the moisture condensed through the night before the sun acts powerfully upon the house. Allow as much lateral extension as can have exposure to light, but growth must not be allowed to extend at the expense of the main leaves. Avoid large reductions of foliage at one time, acting on the little-and-often principle, so as to avoid giving a check to the roots.

Late Houses.—Examine the bunches, removing any stoneless berries, those that are likely to interfere with the symmetry of the bunch, as well as to rectify any defect in under-thinning, so as to give room for the berries to attain their full size without wedging. The shoulders also should be seen to, tying up where necessary, and if there is a larger crop than the Vines are likely to perfect, remove at once some of the least promising bunches. Thorough supplies of water or liquid manure should be afforded, and mulching internal borders, alike to maintain uniform moisture at the surface of the border and source of aliment both to the roots and atmosphere by the matter evolved through the decomposing materials.

PLANT HOUSES.

Allamandas.—If trained under the roof of structures where a stove temperature is maintained Allamandas will grow luxuriantly and flower freely. Those started into growth early in the year are certain from this time to shade the plants beneath them unless care is taken to judiciously thin the shoots at intervals of a week or ten days. When a growth flowers a number of shoots start away, and these only crowd the roof unless some are removed. Plants grown in as natural a manner as possible may from this time be used for furnishing the conservatory or other structures kept gay with flowering plants. Formally trained specimens rarely look well associated with naturally grown plants, unless special positions can be accorded them. The best method of training for this purpose is to secure the main branches to four or five stakes placed round the side of the pots, and the young growths and flowers not tied-in too stiffly. Carefully prepare the plants previous to removal, and do not admit cold draughts to them; they should also be carefully watered.

Stephanotis floribunda.—Whether trained upon trellises or under the roof Stephanotis is very liable to become overcrowded with growths. When this is allowed to take place it is almost impossible to keep them free from mealy bug. Those that have flowered, and which are trained to trellises, may have the weak-growing ends of the shoots removed, and if practicable the shoots taken from the trellis and trained under the roof of some structure where they can be fully exposed to the sun, and where liberal ventilation can be afforded. Those trained under the roof may be freely thinned to give more room to young shoots that are only now being produced. These late growths, if exposed to plenty of light and air, will flower freely, and thus prolong the supply. If mealy bug has appeared syringe liberally with petroleum and water—1 oz. to a gallon of the latter. Shade the plant from the sun for a few days afterwards until the oil has evaporated.

Bougainvilleas.—Remove all the weak twiggy shoots from plants that have flowered. It is useless to allow these to crowd the plant until the end of the season. By their removal the plant can devote all its energies to the full development and maturation of the strong shoots that will be needed another year. These plants are very useful for furnishing the conservatory during the time they are in flower; the cool airy temperature will suit it admirably. The flowers and foliage will both be of a much darker shade of colour than when grown in heat.

Clerodendron Balfourianum.—Clerodendrons that have made luxuriant growth since flowering require lighter, cooler, and more airy quarters, as in a close moist atmosphere they will continue growing, instead of having their wood well ripened by autumn. Plants in this condition and all in active growth should be liberally supplied with water, and those that have been in their pots for some years may have weak stimulants. Those intended to flower again should have little more than greenhouse treatment. Keep them on the dry side at their roots—in fact, if they have completed and fairly well matured their growth water may be withheld until the plants flag. This will quickly have the desired effect of bringing them to rest.

Caladiums.—If not grown in too much heat and now in healthy condition Caladiums may be gradually hardened and removed to the conservatory. They will last for some time in this structure provided too much air is not admitted directly upon them. These plants add considerably to the attractions of such structures at this season of the year.

Dracana Cooperi.—This and other varieties that were raised from the root portion of the stem for various decorative purposes may now be placed in 5 and 6-inch pots, which are the most suitable sizes for them. After they are potted place Selaginella on the surface with a few pieces of *Panicum variegatum* intermixed. This adds to the appearance of the plants materially, and will last fresh considerably longer than if the surface is covered just when the plants are to be used. Grow these plants in a moist atmosphere, but where they can be shaded from the sun.

THE BEE-KEEPER.

WORK FOR THE MONTH.

THE present year has been a season of grievous disappointment "Hope deferred maketh the heart sick," yet bee-keepers have continued to hope against hope until at last the month of July drawing to its close warns them that the year is speeding away and there is no further possibility of a surplus being obtained unless the stocks are in or can be brought into the proximity of Heather. Few bee-keepers will be suicidal enough, we hope, to neglect their stocks at this critical juncture. Every stock should be at once carefully examined, and there should be no delay in carrying out all necessary manipulations.

Every stock in the apiary will require some assistance, and not a few will require some 20 lbs. of syrup in order that they may be in a fit state to brave the winter. Breeding must be encouraged, and consequently feeding must be resorted to; in fact in well-managed apiaries strong stocks have had food given them for some weeks past, and such stocks are consequently now crowded with young bees, and will be in a condition most favourable for wintering some two months hence. Queens will require to be examined, and those which seem to be under the mark must be destroyed and their place filled up with mothers of a younger age. This manipulation may, however, be delayed with some advantage until the young bees necessary for safe wintering have been reared, because by such delay we get the greatest part of this year's work done by the old queen, and then by introducing the young queen in September, no heavy call is made upon her until the following spring; we conserve, as it were, the energies of the queen upon which so much depends in the future at the expense of the queen whose work is almost done.

Food should not be administered too freely at the present time, but when stocks are absolutely in want a copious supply must be administered. There must be no spilling or messing about of the syrup, otherwise the apiary will soon be in an uproar, and great inconvenience will be the consequence. All feeding must be carried on at night, every feeder carefully covered, and all cases which contain syrup should be carefully stowed away in a place to which the bees cannot gain access. Supers and other extra room must be removed, and the apiary may now at once be got into winter quarters, save that no stocks should, in our opinion, be united at present, provided each stock has at its head a laying queen, because accidents may happen in the next few weeks which will make us glad of an extra queen, and also because in each stock young bees are being continually hatched out; and therefore, as in the next few weeks many old bees die of old age or are lost at their work, we have when the uniting is done a greater proportion of young bees than if the manipulations had been carried out at an earlier date.

All swarms must be returned to the stocks from which they issue, or they may be used in strengthening other swarms which have not made satisfactory progress; but the season is now so far advanced that few swarms will now be thrown off, many stocks being considerably weaker in numbers now than they were some three months since. Bee-keepers must not delay. Time is the essence of success. Each day is important, and the work of a single day may leave its mark on next year's success. Where brood is ejected no other sign is needed. The flag of distress is hoisted, and unless succour is given disaster is imminent to such a stock. A few shillings spent in the purchase of sugar now will be repaid tenfold in the future, and we must not forget that a cycle of good years have blessed us with plenteous harvests, and that therefore we should be the better able to withstand a season of adversity and disappointment.—FELIX.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Lilium giganteum (T. T.).—We should be pleased to see a photograph of your plant, as it is seldom this Lily flowers so satisfactorily.

Allamanda from Stopping to Flowering (U. S. B. L.).—With the shoots an inch or 2 inches long from the last pinching the plants may, if they are of a floriferous nature, be had in flower in six weeks, but much depends upon the condition of the plants.

Humea elegans (Alee).—The cold winds in May were one of the causes of this plant losing so much of its foliage, as we have plants 10 feet high with the same fault; but as they are flowering well at the top we must not object to their naked stems. Do not by any means cut it down.

Heating a Small Conservatory (Mrs. B.).—No stove without a pipe or chimney ought to be admitted among plants—it slowly destroys them. We had such a small conservatory once, and we heated it by a gas stove, but with a pipe to carry off the fumes resulting from the combustion of the gas.

Tuberous Begonias (H. J., Birmingham).—The Post Office authorities disregarded your directions, and the box arrived in a smashed condition without any letter. A few flowers remained in the corner of the box, and these are excellent examples of a double scarlet Begonia of good shape and brilliant colour.

Implement to Carry Large Plants in Pots (U. S. B. L.).—If they are too large for an ordinary hand-barrow they could be moved by means of two stout wooden rods or iron bars, one each side secured to a chain encircling the pot below the rim. Chains are sometimes used, furnished with large strong hooks at the side for fixing in the bars, or sometimes hooks are fixed in the wooden rods and then inserted in the chain. Several other methods of a similar character will suggest themselves to you on a little consideration.

Earwigs Infesting Climbers (R. O. M.).—These pests can only be successfully dealt with by trapping, than which for your purpose few things are better than Broad Bean stalks cut into lengths of 5 or 6 inches, and placed horizontally in different parts of the trees or plants. The hollow stems of Hemlock, Sunflower, and Jerusalem Artichokes are equally applicable. The traps should be examined every day and the earwigs blown out into scalding water. Earwig traps, which may be had of most nurserymen, will prove effectual if well attended to. The climbers may be syringed with a solution of softsoap, 2ozs. to the gallon of water, adding a pint of tobacco juice, which will make the plants distasteful to the pests but will not kill them. Perseverance in trapping is the only remedy we know.

Lawn Weedy (T. R.).—You propose to pare off the turf as thin as possible, then fork it over, picking out the Dandelion roots, give a dressing of artificial manure and sow the best lawn grass seed, and this is a capital plan, but we should not confine the picking to the Dandelion but extend it to all perennial weeds, and repeat the forking so as to thoroughly cleanse the soil of the roots of the weeds. The seed may safely be sown in the second week in September, and if you could afford a dressing of short but not very much decayed manure in early November, it would assist the grass through the winter and insure an early and good growth in spring. A cleanly and good tilth is of primary importance, and it is necessary that the seeds be sown sufficiently early in autumn to insure a good growth before winter, or if there is not time to effect it sowing would be best deferred until spring. We have sown grass seed up to early October with satisfactory results.

Ornamental Trees and Shrubs for Filling up Shrubberies (E. A.).—Robinia inermis, Ailantus glandulosa, Almond, Amelanchier Botryapium, Bird Cherry common, and Virginian, Double-blossomed Cherry, Chestnut (double red, pink or scarlet, and yellow); Cotoneaster frigidula, Laburnum vars, Liquidambar styraciflua, Crab, Japan, &c.; Maple, Variegated, Ash-leaved, and Red Colchic; Mulberry, black; Plum Myrobalan, White Beam, Mountain Ash, and Double Thorns in variety. Those are trees or semi-trees. Shrubs:—Aucuba japonica, Berberis Darwini, Box, Handsworth and variegated; Broom, Spanish and White;

Cotoneaster Simmons; Elder, New Golden, Guelder Rose, Kerria japonica, Laurustinus; Lilac, vars; Philadelphus grandiflorus; Privet, Chinese, and latifolium novum; Spiraea arifolia, Sweet Briar, and Double Whin. Write to Low, Marston & Co., Fetter Lane, E.C., respecting the books mentioned.

Vine Spurs (D. W.).—In the house referred to the spurs, owing to the strength of the laterals and the size of the leaves, ought to have been about 15 inches apart along each side of the main rods, or in other words, the Vines, if 18 feet long, would be adequately furnished with twenty-four laterals, twelve on each side, for bearing fine Grapes. The best Grapes produced near the town in which you reside were from Vines the laterals of which were more thinly disposed. We have seen a Vine this week with the laterals more than 18 inches asunder (some 2 feet), the bunches of Grapes ranging from 4 lbs. to 7 lbs. each. Root action does not depend on the number of leaves and growths, but on their quality. All Vines are not alike, and possibly 15 inches between the spurs might suffice in your case, but nine persons out of ten err by overcrowding the foliage. Your suggestion respecting the Orchids shall have our attention.

The White Beam Tree (M. A.).—The tree of which you require the name and uses is the Pyrus Aria of botanists, and is commonly known as the White Beam Tree, in reference to the white under surface of the leaves. It is a native of Britain, chiefly in the mountainous districts on limestone soils. Its fruit is acid and astringent, but is not disagreeable to eat when in a state of incipient decay, like the Medlar. When dried and reduced to powder it has been converted into a sort of bread during times of scarcity both in France and Sweden; and when fermented it forms a beer, or, by distillation, a powerful spirit. It is greedily eaten by birds, for which reason the trees are ordered to be preserved in French forests, that the number of birds may be increased, in order to keep down the insects. The fruit also furnishes food to squirrels, and when it drops, deer and the hedgehog eat it with avidity. The wood is very hard, of a fine close grain, yellowish white, and susceptible of a high polish. It may be stained of any colour, and is much used in making handles of knives and forks, wooden spoons, and for musical instruments, and various articles of turneryware.

Budding Manetti Stocks (B. T.).—The stocks being in rows earthed up like Potatoes, take a hoe or spud and remove the earth from the stock, so as to insert the bud as low as possible. When this is done proceed to cut the bud just the same as you do for the Briars, and make an incision as low as you possibly can; the lower down the better, as the fewer will be the suckers—indeed, you should almost bud on the roots, if possible. At any rate, strive to insert the buds as low as you can. Only insert one bud in each stock. Choose the same side of the stock all down the line, and also select a place as free from knobs or irregularities as you can find. Make the incision in the form of a T, and when the bud is safely in tie up well beyond each end of the bud with rough cotton or worsted. Ladies often use wool, and nurserymen, bass or raffia or cotton. You must not replace the earth, but leave the bud showing, or rather the cotton, so that in the course of a week you can see whether the bud has taken or not. If it has not bud the other side of the stock. Do not touch the Manetti shoots, but leave them to grow as luxuriantly as they will till the following spring; then remove the cotton and cut back the Manetti to the bud. The best time for budding the Manetti is after rain, and if you have no rain give the stocks a copious watering, and you will find the bark run. August is the best time for budding Manettis. All the varieties you have named do well on the Manetti; in fact, all Hybrid Perpetuals except La France, which, having some Tea blood, never does so well on this stock as on the Briar.

Galls on Lime Leaves (Hortus).—The samples sent are what have been popularly called Lime Leaf Nail Galls, attributed to a gall mite named Phytoptus Tiliæ, though it is uncertain whether under this name more than one species may not be included. Upon their first appearance these galls are green, then they become yellow, this passes into red, next they are purplish, and finally brown. Their history is interesting, since the Lime was observed to be thus infected more than 150 years ago by the celebrated naturalist Reaumur. He was, however, much puzzled by them, and discovering in some of them a solitary larva, he supposed they were produced by a kind of fly or beetle. If he was right in his observation such larvæ could only have entered in order to prey upon the mites such galls may contain, for they are not attributable to other insects. So small and transparent are these mites that it is difficult to find them, and the plan generally adopted by naturalists is to wash them out with water, and then examine the liquid. On opening one of these galls it mostly appears to be full of hairs of a peculiar growth caused by the punctures of the mites. It cannot be said that the history of these galls is as yet properly elucidated, and it is maintained by some that the mites which they commonly contain are not the real parents of the galls, but "inquilines," or after tenants. Nor can we say how it is that of two trees, seemingly growing under the same conditions, one will be found swarming with galls, and the other almost as entirely free from them.

Large Mushrooms (F. H. G.).—The Mushroom reached us in an extremely uninviting condition, but it is evidently Agaricus arvensis, which is occasionally found as large as the specimen sent—namely, a foot in diameter. It is nearly allied to the common Mushroom, so nearly indeed, that it is scarcely better entitled to rank as a separate species than the varieties pratensis and silvicola are; but it is accounted distinct

by many authors. The Horse Mushroom has a dome-shaped pileus, bell-shaped in youth, and expanding in maturity, generally of a pure white colour and cottony texture, but losing its downy appearance in age; and a veil consisting of a double membrane, thick, woolly, falling from the edge of the pileus, and hanging loosely round the stem; the gills are free, pale pinkish brown, becoming darker as they grow older; the stem is cylindrical, the cavity filled with cottony pith. The flesh turns yellow when bruised. Occasionally the pileus is tinged with brown. It attains a large size. Authorities are at variance as to the manner of its growth. Mr. Berkeley describes it as growing in rings, and Mrs. Hussey does not number it among those addicted to circular growth. When it does grow in rings they are of a very large size indeed, and as they are seldom perfect it is easy to overlook the relation which one group has to another. Fields and woods are the habitats of this Mushroom; those growing in the former are the most wholesome. They should not be taken in the button stage like the *A. campestris*, but are in perfection just as the veil has broken away from the pileus, and the bell-shape is merging into the dome. In this stage, and later if free from larvæ, the Mushroom is excellent fried or stewed, and for this purpose is sold in Covent Garden Market. It is one of the best Mushrooms for making ketchup, its large size being a great desideratum in this matter.

Trees for Small Orchard (Mulberry).—We presume your proposed orchard is really to be a fruit garden, the ground not being under grass as in orchards generally. In the case of a fruit garden, pyramid, bush, espalier, and cordon are the best trees. Standards are only suitable for culture on grass where the ground under and between the trees and rows can be utilised for crops that are not required in private establishments to the extent they are produced by the large culture system. Espaliers are extremely useful from a sheltering point of view. We should advise a line to the north and on the east and west sides of the plot, 6 feet high above ground, the wires 10 to 12 inches apart. These we should cover with the hardier Apples, so as to form a strong screen for sheltering the other parts of the plot. The ground may be further divided into plots by lines of espaliers running north and south so as to still further break the force of winds, and these may be used for cordon-trained trees. The intervening spaces or quarters will be available for bush and pyramid trees. A cordon orchard or fruit garden is simply delightful. The diagonal cordon tree may be planted 2 feet or even 18 inches apart, but the larger distance is best. The lines of bushes or pyramids should be 7 feet 6 inches from the espalier lines, which will allow of ample space for cultural operations. Apples should be grafted on the English Paradise stock. They may be planted 4 feet 6 inches to 6 feet apart, the lesser distance for bushes and the larger for pyramids. Pears should be grafted or budded on the Quince or double-worked in the case of those that do not succeed on the Quince. They require about 18 inches more space than Apples. Plums should be planted 7 feet 6 inches apart, and if they grow too vigorously they should be lifted early in November. Plums are best trained as pyramids. Bushes may be planted 4 feet 6 inches, and pyramids 6 feet apart. Duke and Morello sections succeed on the Mahaleb stock. Bigarreau Cherries should be double-worked. For the espaliers, if you do not have cordon trees, dwarf-trained trees should be planted 12 to 15 feet apart, Pears 12 to 15 feet, Plums 15 to 20 feet, and Cherries the same as Plums.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. G.*)—*Zenobia speciosa* var. *pulverulenta*. (*W. K. R.*)—1, *Epilobium angustifolium*; 2, *Lythrum Salicaria*; 3, *Centaurea montana*; 4, *Convolvulus mauritanicus*. (*J. H.*)—Very poor varieties of Sweet Williams, much better are frequently seen.

COVENT GARDEN MARKET.—JULY 25TH.

OUR market has been very active the last few days, large supplies of soft fruit reaching us, prices being fairly good.

FRUIT.

LESSONS FROM PRIZE FARMS.

THAT the Royal Agricultural and kindred societies have done and are doing much for the improvement of agriculture, is an acknowledged fact to which due recognition is accorded by all sensible people, and in nothing have they done better than in the prize competition for farms. Sound practical men of mature experience are selected as judges, and the work of inspection is thorough and exhaustive. Much good is done by such competitions, both to the managers of the farms and to those who see the results of their practice or read the lucid reports of it given in the journals of the different societies. Year after year have we read these reports with keen interest, and from the first the feeling has grown upon us that the lessons taught by them were of vital importance to farmers generally. Let not anyone suppose that the prizewinners are exceptionally fortunate men whose lines have fallen in model farms and soil of superior staple. On the contrary, many, if not most of them, have had many difficulties to overcome by dint of downright hard work, the outcome of energy combined with intelligence.

Take, for example, the first prize farm of the recent contest near Nottingham. It is much exposed, with little or no shelter for live stock; the soil is light, dry, and so sandy that the surface is often blown about by the wind. It contains much silica, part resting upon new red sandstone and part upon magnesian limestone, and is altogether difficult soil to maintain in high condition. All the more credit is therefore due to Mr. Machin for winning the premier prize of £100. But then the prizewinner and his family are all remarkable for intelligence, energy, perseverance, and mechanical ingenuity. We are told in the report of a covered yard erected at a cost of 2s. 7d. per square yard, of manure made so well in it that clear proof of its excellence was afforded by the crops for which it had been used. Of the superior convenience of other buildings; of the clever adaptation of machinery to special purposes; of superior farm produce; of well-kept hedges; of

every foot of space upon the land being turned to account, either for main or catch crops; and of profitable poultry keeping.

Turning to reports of other farms in other competitions, we are told of well-farmed pasture in good herbage, free from noxious weeds, and in good heart, on soil and subsoil gravelly and light. Of a profitable system of management of dairy cows, under which only very fine cows recently calved or near calving were purchased, fed well, kept only so long as they yielded a full flow of milk, and then passed on to the butcher in ripe condition for killing. The dietary in this case consisted of hay, turnips, pea meal, maize meal, or other cereal food of good quality mixed with brewers' grains, cut chaff steamed and seasoned with sugar or molasses, the practice being to watch the markets and food which was cheapest and best. On another farm each cow had 6 lbs. of barley, or 3 lbs. of barley and 3 lbs. of maize meal per cow, with hay and turnips, alternating with $7\frac{1}{2}$ lbs. barley, 21 lbs. of hay, and 42 lbs. of turnips. Another mixture used on this farm which was described as both satisfactory and economical, consisted of

	£	s.	d.	
Two tons of coarse barley at ...	3	5	0	per ton.
One ton best barley meal at ...	5	10	0	"
One ton wheat sharps at ...	4	10	0	"
One ton oatmeal dust at ...	1	10	0	"

The cost of this mixture was $5\frac{1}{2}$ d. per 14 lbs., or £3 13s. 4d. per ton. Cotton cake was not used at all. Cows had often been lost from milk fever when it was used, but none had been lost since it was given up. We may remind our readers that the different sorts of food mentioned were used for cows kept solely to produce milk for sale, and not for cheese or butter.

In other of the reports we find mention of the adaptation of farms to surrounding circumstances; of the profitable growth of fodder for use in its green state and for hay; of town stable manure used profitably for suburban farms; of the culture of farm produce of all kinds for special local requirements; and above all of successful results achieved throughout the depression. In every instance the farm and its duties were the sole interest of the occupants. We are told of Mr. Joseph Lambert of Whickham that he and his wife had their hearts in their farm and in its success. They fed their cows liberally, cared for them almost as for their children, and spared neither thought, labour, nor outlay to make them profitable. It was this gentleman of whose big white cow Beauty we are told that in 1887 "she had not been dry for nine years, but had milked continuously, and given as much as thirty-six and thirty-eight quarts of milk daily, keeping to this quantity for four months after calving, and never going below nine or ten quarts per day. She had had a calf every year for seven years, but only one in the last eighteen months. She was then nearly blind, but in good health. She was a great feeder, and would eat nearly as much as two cows."

WORK ON THE HOME FARM.

Glad indeed were we to note an improvement in the weather, and the haymaking has been going on briskly. A rising barometer and clear sky gave fair promise of a continuance of fine weather, and a consequent considerable reduction in the expense of haymaking, as well as much improvement in the quality of the hay. So far we have sustained no serious loss from spoilt hay, nor has there been any risk of fire from excessive fermentation. There has been a high temperature in each risk, and this is especially desirable to impart flavour when much rain has fallen upon mown grass. Under careful management so-called spoilt grass from exposure to rain becomes sweet and palatable. The one evil for which there is no remedy is mouldiness, which arises from carting hay that is damp or insufficiently harvested.

Bright hot weather now is also much required for the corn. We have seen some magnificent crops of Wheat, Barley, and Oats since writing our last note, and have had pleasing evidence that more attention is being given to the selection of pure seed. The Barley consisted of remarkably well-developed Chevalier and Beardless, the latter being especially recommended for deep rich soil or heavy land, and the former for general cultivation. The Wheat was a popular selection of Squarehead, termed Squarehead's Master, which is really a pure and fine sample of Squarehead. "There!" said the farmer, "that is a fine break of Wheat," and we entirely agreed with him. It was in one large field of fifty-two acres; the crop was thick on the land, with fine bold ears of large grain, the straw of that robust growth peculiar to Squarehead, and of a uniform height of about 4 feet. To anyone who thinks Wheat-

growing is dying out in this country, we say, Go and see such a crop, and conviction must follow that under such high culture Wheat-growing is still profitable. All corn has wonderfully improved, notwithstanding the low temperature of the first two weeks of the present month, and none more so than Winter Oats, which were never finer either in straw or grain, but they will not be ripe enough for mowing till August, nor will Rye be ready till the end of the month. As a late harvest is now inevitable we shall employ a few more men than usual on every farm. The expense will be the same, as the work will be over in less time if only the weather prove favourable.

BRITISH-GROWN TOBACCO.

THE report of the Judges appointed to determine the award for the prize of 50 guineas offered by the Tobacco section of the London Chamber of Commerce for the best specimen of British-grown Tobacco was circulated on Saturday. The Judges were Dr. J. Bell, F.R.S., Somerset House; Professor W. Fream, LL.D., College of Agriculture, Downton, Wilts; Dr. J. Augustus Voelker, Mr. Henry F. Moore, Frome, Somerset; Mr. W. H. Wills, Mr. James Biggs, Mr. Louis Morris (Tobacco Manufacturers), Mr. Algernon Gilliat (Merchant), Mr. James Chambers, Mr. G. H. Ball (Tobacco Brokers), and Mr. C. A. Müller (Tobacco Importer). The conditions originally laid down by the Tobacco trade section of the Chamber when the prize was offered required that each specimen submitted for the competition should consist of a not less quantity of Tobacco, grown on a commercial scale, than 400 lbs. in weight. It was also stipulated that each sample should embrace an average of the crop grown, and that such particulars should be given by the growers as would assist the Judges in making "a report on the yet doubtful question as to the possibility of growing Tobacco in Great Britain such as in quality relatively to price can compete with that of other countries." The various entries of Tobacco, numbering eleven in all, were duly inspected by the whole of the Judges on May 14th at the Fenchurch Street Warehouse. It was found that only four exhibitors had complied with the conditions of the competition so far as quantity was concerned; but, in view of the interest which is being manifested in regard to Tobacco-growing in the United Kingdom, the Judges considered it desirable to present a supplementary report on the remainder of the specimens, though not properly coming within the scope of their adjudication. They placed the four exhibits submitted to them in the following order of merit:—First, Messrs. James Carter & Co.; second, Mr. W. L. Wigan; third, Sir Edward Birkbeck, M.P.; fourth, Mr. John Graves; and they recommended that the prize of 50 guineas should be awarded to Messrs. James Carter & Co. Detailed particulars, furnished by the growers, as to the cultivation and preparation of the Tobacco sent in for competition are given, together with remarks of the Judges on the various exhibits. Closing their report with certain "general observations," the Judges state that, speaking generally, "not one of the four samples eligible for the prize was in any respect valuable for trade purposes, or even merchantable, presuming that no duty was chargeable upon the article. Still, it was evident that well grown Tobacco-leaf can be produced upon English soil, though, of course, this admission in no way takes account of the cost of production. . . . With regard to the prospects of Tobacco-growing on a remunerative basis in England, we share the opinion that, even under the most favourable conditions possible, such a crop cannot be made to pay, and that in most seasons it must be an absolute failure and heavy loss. The climate of this country, to begin with, is less favourable than that of Kentucky or Virginia, and the cost of production will be found far greater here than in the United States. Until the curing of Tobacco is perfectly well understood in the United Kingdom the finest leaf that can be grown will be absolutely wasted and useless."

REMARKS.

15th.—Wet all day, thunderstorm at night.
16th.—General y cloudy and threatening, with occasional spots of rain.
17th.—Bright and fine till 10.30 A.M., then cloudy, with haze in afternoon, getting unusually thick about 5 P.M.; very heavy rain, with some lightning and thunder from 6 P.M. to 6.30 P.M., and wet evening.
18th.—Dark and threatening morning with frequent spots of rain; frequent thunder in afternoon, with showers, fair evening.
19th.—Overcast till 11 A.M., then fine and bright with the exception of a slight shower about 2 P.M., and heavy rain from 5.20 to 6.20 P.M.
20th.—Wet till nearly noon; fair afternoon and evening.
21st.—Fine, with occasional sunshine.
A damp and rainy week, with frequent thunder. During the storm on the 17th the rain fell for some minutes at the rate of 4 inches an hour.—G. J. SYMONS.

THE POTATO DISEASE.

PRACTICAL immunity during recent years from the scourge that for a long time wrought such havoc amongst the most important of all root crops, led to the hope, somewhat widely entertained, that the destructive murrain was stamped out. We were never sanguine on this point, and have more than once intimated the possibility, or rather probability, of its reappearance when the conditions became favourable for the growth of the fungus on the leaves of the plants. It is only natural and reasonable to suppose that the absence of the disease for three or four years must have lessened materially the number of spores of the *Peronospora*; but no one appears to know how long the resting spores retain their vitality, though it is well known that when they germinate, and wet and warm weather prevail, the parasite increases with alarming rapidity and speedily ruins the crops in which it becomes established.

Having a clear remembrance of the first great outbreak of the Potato disease in 1845 we have watched its course, its ebbing and flowing, with much interest ever since. Broadly speaking, it comes with wet seasons and increases in proportion with the continuation of the rain and dull weather, influenced considerably by temperature; and during hot and dry summers it is scarcely seen. The summer of 1845 was like that of 1888. In a large Potato-growing district the ground was saturated and water stood between the Potato rows in gardens and fields. The early part of the season was cold, but the temperature rose towards the end of July, thunderstorms were frequent, clouds heavy, and the Potato growths seldom dry. The fields were like a reeking swamp, and then came the outbreak. No one knew what it was, nor how or whence it came. To this day the latter part of the problem remains unsolved, but the microscope under the eye of keen observers revealed the former. We know what the disease is now, but we do not know its origin or the agency by which it was introduced forty-three years ago. Many theories have been advanced on the subject, but one has conflicted with the other so notoriously, and each in turn been upset by facts, that not one of the said theories has met with anything like universal acceptance. It is of little use speculating on that point; but it is both interesting and serviceable to note the fluctuations of the visitant—its periods of activity and its terms of rest.

In what may be termed the early history of the disease there were years of comparative, and occasionally of almost absolute, immunity from its attacks; and these were again followed by years of virulency. The soundness of the crops for two or three consecutive years led many growers to suppose the enemy was banished. It was thought the fungus spores could not live for more than a year or two; yet when the constantly dull, wet, and murky summer periods came again the disease came with them, no matter how long it had been absent. The sequel of the sudden springing into life of the destructive parasite that was fondly thought to have spent its course, was revealed by Mr. Worthington Smith's great discovery of the resting spores of the fungus, which, phoenix-like, ever and anon would start up as if from its own ashes. After these were found we could feel no security; but experience has taught valuable lessons, which the public was slow to learn, whereby it was shown to be in the power of cultivators to materially reduce the injury that the enemy was capable of inflicting, by raising barriers against its inroads.

When the fungus first took possession of Potato plants, poisoned

the sap, and ruined the tubers, it did then what it has done since and is doing now—attacked the soft-stemmed, thin-leaved, and weaker growers first, the stronger, stouter leaved, and upright growers alone escaping. Some popular dwarf-topped varieties that were much grown when the murrain first appeared were soon exterminated, only the coarser sorts, grown chiefly for pigs, surviving. It is true the dwarf-growing Ash-leaf sorts remained, but that is because of their early ripening, the haulm dying before the fungus spores were prevalent; still there have been a few seasons when the weather was such as to call the enemy into action earlier than usual, and then the Ash-leaved varieties became a mass of corruption, or were only saved by digging them up before they were ripe, or promptly pulling up the haulm the moment the first disease specks were seen. Many old cultivators know that is the fact, and they know also that as a rule the disease does not set in with persistency till towards the end of July or in August, and then only when the weather is similar to that we are now experiencing—excessive wet, little or no sun and wind, and a damp, heavy, oppressive atmosphere.

We have within the past few days seen large patches of fungus-stricken Potatoes in gardens and allotments, and more than that, have purchased tubers in markets half of which were more or less "tainted." Growers of early sorts finding the crops affected are forcing their sale. It is the old practice over again, and unmis- takeable evidence of the presence of the murrain. One of those growers informed us to-day (July 30th) that his "Hebrons" were "going bad," so he had marketed them, except some rows he had left for seed on the chance of their escaping, but he expected most of them would "go." He was urged to take them up at once, but demurred on the ground that as the skins were not set the tubers would shrivel and be of no use for planting. That is an ancient fallacy exploded years ago, and on his being assured of this he hastened home to take up the remnant of his crop and spread the tubers thinly in a shed to dry, not in the sun (if any). When this cannot be done, pulling up the tops, if done soon enough, will save the crop, but cutting them off will not, because the fungus takes possession of the stumped back stems above ground, penetrating to those below, for the tubers are only underground stems called by another name. All early Potatoes should be examined now, and if they are seen to be attacked they should either be taken up at once or the haulm pulled and cleared away. This can be done without dragging up the tubers if they are grasped between the feet standing on the rows, and the tops drawn with a sharp jerk.

A number of varieties of Potatoes are on trial at Chiswick. Calling there on Tuesday we asked Mr. Barron if they were free from the murrain. His reply was in the affirmative; and he made the further remark that the 29th of July was the "fatal day"—the date on which he had for several years first noticed the fungus. We had not known the date fixed before, but it is doubtless near the mark. The varieties in the plot are mostly free to strong growers—the last to be attacked, and the most likely to escape, as some of them may. They were clean and healthy, and it was the 30th of the month. The "fatal day" was past; but passing along a border more sheltered from the wind than the open plot is, the fungus was plain enough feasting on the tops of some Myatt's Ash-leaf. "It struck them yesterday," remarked the guide, "as we should have seen if we had been here." It is not unlikely. It was on the thin small leaves near the summit of the stems—the most vulnerable part; the most resisting are the robust growers, with strong leaf power, that can keep the sap in a pure state by elaboration, and the thick cuticle is also the less penetrable by the parasite. Raisers of Potatoes from seed, ripened by vigorous English varieties of good constitution, have done much to impart confidence in the safety of a crop on which so much depends; and a more intelligent system of seed selection and culture that have been fostered by competition, may stand the country in good stead this year. But for the extended planting of strong-constituted

varieties, and the cultural care exercised, the Potato crop would be in great jeopardy at the present time, and 1888 would probably have to be added to the disease years of the past ; as it is, we hope for a better record.

CABBAGES FOR SPRING.

EVERY garden owner tries to have Cabbages for the early spring, but all do not succeed, and this is why I am devoting a chapter to the subject. The Cabbage is a favourite vegetable in market gardens, aristocratic gardens, and with amateurs and cottagers. All that has been written on it would fill a large volume, but I venture to think that something can yet be said, and the subject is seasonable at the present moment.

It is often said of extensive classes of vegetables, such as Peas, Radishes, Potatoes, &c., that two or three dozen names do not represent more than half a dozen varieties ; but in my opinion this does not apply to Cabbages. I do not know a class of vegetables more distinct, and anyone growing from twelve to eighteen varieties, as I have done, can readily see that they vary much, not only in appearance, but also in the time they take to gain maturity. There are very short and compact-growing ones, of which Ellam's Early is the best type. Then we have medium ones and others which gain a great size with loose leaves before they heart. The latter are never early, but do well as second or third earlies where space can be devoted to them. Ellam's is undoubtedly very early, but it is rather too small to suit some growers. Early York, once a favourite Cabbage, is not in favour at present, and never will be again. It is too tall, and is very apt to "bolt" or flower before hearting. We have lost more of it in this way than of any other variety, and they differ much in this respect. We have had whole rows of some varieties run to seed prematurely, where others close to them were not in any way noted in this respect. All points considered we are greatly in favour of Webbs' Emperor as an early Cabbage. It has a capital constitution, it is medium in strength of growth, compact, produces a neat conical head, and is exempt from "bolting." We depend on it as a main crop variety. In the spring just past we tried amongst others a new American variety with high recommendations, but it turned out one of the most mixed and useless we ever had. It is cases of this kind that induce us to recommend growers to adhere largely to some well known and thoroughly tried sort. When you see a Cabbage produce many large loosely arranged leaves it may be concluded that it is not good for early spring, and only those which grow compactly from the first are likely to prove useful.

So much for varieties ; now for the time of sowing. Here we come to a question of the greatest importance. It will never answer to sow Cabbage seed early in July to make sure of the plants being ready in good time. Neither will it do to sow the seed very late in autumn ; indeed, chance sowings must be avoided, and the greatest attention must be given to particular dates. We have tried them at all times, from the last week in June until the middle of September, until we have ascertained without doubt that the last week in July and the first week in August includes the period when spring Cabbage seed may be most successfully sown. A day one way or the other does not make much difference, and very little attention need be given to sowing in north or south, as at this season young Cabbages will grow as fast in Scotland as they will in the south of England, and all Cabbage seed sown now will produce plants that will be in good condition by November. It is at that time their wintering begins, and if they are dwarf and robust then they are sure to be in good condition for heading in the early spring.

A half-ounce or 1 ounce packet of seed will produce sufficient plants to fill a large quarter. Indeed, either of these quantities would be enough for a cottager's or amateur's garden of the ordinary kind, and 2 ounces of seed would supply a large garden. The whole may be sown at once. Let the ground be well manured and forked, and sow in a bed about 4 feet in width. Do not put the seed in rows, but sow broadcast very evenly and not too thick, or when the plants come up in close masses they are apt to suffer before they are ready for planting out. A little soil should be thrown over the seed from the sides of the bed, and then beat it level with the back of a spade. The young plants will be through the soil in a week, and I have known birds pick them up at this time. They sometimes destroy a bed before one knows they have noticed it, and a little lime or soot should be sprinkled over the plants as soon as they appear. If this does not check them place a net over them, and keep it on until the plants are several inches high, and on no account allow the plants to fail from neglect, as if those fail that were sown at the proper time later ones would not be so suitable for the spring. I have known caterpillars destroy some of the plants too, and they must also be checked by hand gathering. In

four or five weeks hence the plants will be ready for putting out in their bearing quarters, and selecting a proper position is of some importance. Remember they will be the earliest vegetable crop in the garden next spring, and they should have a very warm sheltered position. A moderately rich soil suits them better than too much manure, as this only forces them into a luxuriant growth in the autumn, which they cannot sustain throughout the winter. In fact, I do not like to see the spring Cabbages too large in November, and prefer them very sturdy and close in the leaves. They are best too when very dwarf, and when allowed to remain in the seed bed until they have stems about 1 foot in length is ruinous. Such plants are blown about in the winter time, and never succeed. Although I recommend that the seed be all sown at one time, the Cabbages may be planted at different times. We generally make three plantations ; the first as soon as the plants can be conveniently handled, the second three weeks afterwards, and the third early in the following spring. Should the weather be very variable the second plantation may be the best, or *vice versa*. As a rule, we plant at a distance of 20 inches between the rows and 18 inches between the plants. They are put well into the soil, and the soil round each is trodden firmly, as they root much more freely and securely when in firm soil. Some plants may fail in the rows before the winter is over, and these blanks should be filled from the seed bed.—A KITCHEN GARDENER.

STATICE PROFUSA.

THIS Statice is one of the most useful of summer and autumn-flowering plants ; under fair cultural treatment yielding better results in the shape of a continued supply of bloom than can be had from most plants. As an exhibition plant its merits are well known, the same specimen, if kept in good condition, being available for show purposes from April or May until autumn. Its great merits as a house plant are not, I think, so well known, but according to my experience no flowering plants stand employment in rooms better. It occupies much the same position as *Aspidistras* amongst foliage plants for good behaviour under a long-continued course of room decoration.

The culture is so simple that it would hardly be worth while stating particulars were it not that, like all other plants, it shows a decided preference for little attentions, which make all the difference between securing good healthy plants and those that are not so presentable. Taking a cutting in spring (a side slip broken off a shoot is best) I find it root quite freely inserted among the sand in a propagating pit. Cuttings also strike readily in a stoye inserted amongst the sphagnum in baskets of *Aerides*, &c. When well rooted place these into 3 or 4-inch pots ; a compost of turfy loam and fine cowdung suits them well in all stages of growth. Pot rather firmly ; keep the plants growing freely in a warm temperature, with plenty of water at their roots, and all flower growths pinched off as they appear. A shift into a 6-inch pot will be required during the summer, and if well treated the plants will commence flowering the following spring, and may be kept in good health in the same pots by means of surface dressing of manure for a few seasons. However, where young plants can be conveniently raised annually these will be better.

The main thing to be observed with these young plants is never to allow them to stop growing summer or winter until wanted to flower. A winter temperature of 50° to 55° is not too high for them. If specimen plants are wanted quickly continue shifting them into larger pots—a 9-inch size will suit them the second season, and an 11-inch the third, after which biennial shifts will do, or the plants may be allowed to remain in the same pot for several years.

The other cultural requirements are seeing that no flowers appear until specially needed, that the plant continues growing without check (though during winter only slowly), and to keep the foliage free from red spider, which latter sometimes attacks this plant. Our plants are freely watered, and during the summer and autumn months are supplied with manure. We cut spikes of flowers as wanted, and others are thrown up to take the place of those so removed. This plant will stand a low winter temperature, but it is not good for it ; the lowest is 45°, and in February a little heat is of the greatest advantage in securing a finely bloomed *Statice* throughout the season. It may be added that in repotting the plants the stem should not be buried, but, on the contrary, kept rather up from the soil.—B.

A DISASTROUS FRUIT YEAR.

THE present season may well have this term applied to it. I write from observation of a wide district and reports from others. 1887 was a splendid season for maturing fruit wood. Grand results were anticipated from this, but I fear in the majority of cases these

have not occurred. Pear blossom was very plentiful, and Pears are rather a good crop, but Apples did not bloom profusely, and the crop is much below the average, indeed, I fear it is the worst of all the fruit crops. Strawberries were promising at one time, but daily rains caused many of the fruits to decay before they could be gathered, and not a few decayed without ripening. Our crop was heavier than in the dry summer of last year, but it was far from good. Raspberries have been abundant, but very watery and flavourless. Red and White Currants are below their usual size, so are Black Currants, and all are deficient in quality. Many of the leaves are falling off the Red and White Currant bushes, and life is stagnant in all of them. Apricots are quite green and small as yet. Plums are not half grown, and Peaches in the open are not stoned. Last year I gathered Hale's Early on the last day of July, this year they will not be ripe by the 1st of September. The Alexander Peach was planted under the recommendation that it was so much earlier than Hale's, but at the present time it does not show this character. I am of opinion that a fine June and July are the months above all others from which good fruit of all kinds may be expected, and when these are ungenial a fine August or September fails to compensate for them, as the nights soon begin to cool, and the trees and bushes never regain full vitality. I have already put 1888 down as a failure as a fruit year, and I have no expectations of anything occurring to alter this. The worst of it is beginners in fruit culture are apt to be daunted by poor results, but I do not go so far as that; and when we have three or four good fruit years in succession, as we have had many times, we can overlook a failure or partial failure without much grumbling.—J. MUIR.

THE POTENTILLA.

THIS showy hardy perennial is very useful for cutting from during the months of May, June, July, and August. It may be readily increased by transplanting or potting divisions of the roots or side shoots in the spring just as growth has commenced. The plant is not particular as to the situation or soil it is planted in, but the more favourable the conditions under which it is growing the better will be the results secured when the plants are in flower. A position fully exposed to the sun and a rich loam to grow in are conditions calculated to produce the best possible results. The plant may also be propagated in August from seed sown in shallow boxes filled with light soil, covering the same lightly, giving water through a fine rose, and placing in a close frame. When the seeds have germinated, prick the young plants out a few inches apart in boxes or a warm border when large enough to handle, preparatory to being finally transplanted into their flowering positions before they touch the boxes and nursery beds.—W. H.

VEGETABLES FOR EXHIBITION.

SETTING UP COLLECTIONS.

AT the commencement of my exhibiting career vegetables, although largely shown, were the least attractive feature at the majority of shows; in fact they were not considered worthy of a very prominent position. Now-a-days, instead of being either outside the tent or underneath the side staging they receive much better treatment, and are by no means unattractive to the visitors. Much of this improvement is due to the superior manner in which they are staged, and there is no reason why they should not always hold an honourable position. Mr. G. T. Miles, Wycombe Abbey, was one of the first to take extra pains in displaying collections of vegetables to the best effect, and while he continued to compete no other exhibitor excelled him in this respect. The mere fact of the vegetables being set up to the best advantage will not alone insure their taking the first prize, but if they are of equal quality to the rest of the competing collections, superior arrangement turns the scale in their favour.

Where a staging is provided for the vegetables, these are usually either set up in dishes or are grouped on the boards, and in either case are more attractive than when shown in baskets. The exhibitor should provide himself with plenty of clean fresh moss and good Parsley, the former serving as a bed on which to raise and display the vegetables, while the Parsley should be neatly arranged so as to form a fringe, more of it being worked in wherever there are any openings for it among the various specimens. It is unwise to smother the vegetables with Parsley, this detracting from their size, and care should be taken not to use more than will suffice to set off the former to the best advantage. Do not attempt any extraordinary mixture or any fanciful arrangement, but let each dish or variety be kept well together. Scattered they are not nearly so effective, and their defects are only too plainly visible to the judges and onlookers generally. How they should be grouped

ought to be decided before the exhibition tent is reached, and all can then be put up quickly and exactly where they are to remain. There need be no flurry, and no arranging and re-arranging of the collection, and those who cannot, or do not, avoid this, run the risk of being turned out of the tent before they have set up the collection to their own satisfaction, let alone to that of the judges.

Groups or dishes of Cauliflowers, Globe Artichokes, Onions, and Turnips are suitable for the back row; in front of these, and arranged so as to form a good contrast of colour, being Potatoes, Tomatoes, Carrots, Mushrooms, and Beet; while Peas, Beans, Cucumbers, Vegetable Marrows, and Celery are usually seen to the best advantage in front, all being arranged so as to form a good slope to the pathway. If the dishes are arranged just clear of each other fill in the spaces between either with good Parsley or rich green moss, this giving a finishing touch to the exhibit. Cover all with paper till such times as the tents are cleared for the judging, and on no account omit attaching both the names of the varieties and the class cards. The last proceeding of experienced exhibitors is to go round and see that the latter are all put on properly, many assistants, and even the responsible exhibitors, frequently contriving to muddle up the class cards (which only good-tempered or not over-worked judges will put right), disqualification being the consequence.

At many shows the prizes are offered for collections of vegetables in baskets, these dispensing with the necessity for putting up extra staging. This system of showing has its advantages, notably in the case of local exhibitors, who can arrange their baskets over-night, or, at any rate, before they leave the garden in the morning; but I much prefer to see vegetables set up on a staging as just described, and baskets or trays are a great nuisance to those who come from a distance. However, a basket of vegetables may be made attractive in appearance, and with a little ingenuity every variety may be shown off to the best advantage, though not if all are sunk into a basket several sizes too large. Nor should any kaleidoscope arrangement be attempted. Many exhibitors seem to think the right thing is to quarter out or divide their basket either with Cucumbers, Celery, and Potatoes, while others go in for circular combinations. Such baskets are confusing to the judges, who have a difficulty in finding the much-divided varieties, and the system, as before pointed out, is the surest method of showing up the defects of individual specimens. Flat baskets, such as plants are sent out in by nursery men, are the most suitable for the purpose, one about 3 feet in diameter usually being large enough for a collection of eight varieties of vegetables. These should be firmly filled with hay, this being faced over with green moss or Parsley. Each variety to be kept in a separate heap, the most showy, or, say, a good dish of Tomatoes or a bunch of Nantes Horn Carrots points upwards, being fixed in the centre, the Cauliflowers, Artichokes, and larger kinds disposed at the back, and the rest gradually brought round to the front. The weight of the vegetables will depress the hay sufficiently to admit of their resting safely without being actually below the rim of the basket, and with the aid of Parsley among the kinds and over the sides they will look really attractive. As these baskets are usually set on the turf, they ought to be slightly raised in front, and be blocked up, with the aid of inverted flower pots, much higher at the back. Always aim to produce a good first impression, as it is not lost upon judges, however keen they may be in ferreting out defects.

Much that has been written upon the arrangement of vegetables in baskets is also applicable to somewhat similar exhibits in trays, only in this case there is no necessity for using any hay, plenty of moss and Parsley being, however, indispensable.—EXHIBITOR.

MELONS CANKERING.

DULL sunless weather is altogether unfavourable to Melon culture, especially in unheated pits and frames, and we have had little else but this for many weeks past. Where plenty of fire heat has been turned on the Melon houses and pits the plants have succeeded surprisingly well, failures being no more frequent than in favourable seasons. They, however, need much closer attention in dull weather, care being taken not to saturate the soil in which they are rooting, a wet and cold heap of loam and old hotbed manure underneath invariably leading to a failure. In addition to watering carefully and the maintenance of a drier atmosphere than is advisable in dry hot weather, a close look up must be kept for any decay of leafstalks or canker in the stem. The oldest leaves, or those on the main stem of plants trained to roof trellises, are the first to go, principally owing to their being unduly shaded. If these are allowed to die slowly the stalks often become suddenly decayed, and in a few hours this spreads to the main stem, the whole plant soon becoming affected beyond recovery. The safest course to pursue is to anticipate this decay of the leafstalks. If

they are cut off close to the stem, the wound dried with a piece of sponge or some substitute, and then dressed with newly slaked lime, or, failing this, Portland cement, the dressing being renewed as often as found in a moist state, the wound soon heals. Any leaf-stalks allowed to become rotten close to the stem must be at once cut cleanly away, the wound dried and dressed with the lime. Sometimes it happens all the principal growths become suddenly diseased, and in a few hours the plants are a mass of decay. This usually happens to overgrown plants when there is a sudden change from hot to cold and sunless weather. It will also result from severe pruning or from a heavy watering. Plants thus affected are rarely, if ever, saved, and it must be prevented by an increase of fire heat and a drier atmosphere maintained.

Canker at the collar, or that portion of the stem from which the first or seed leaves spring, is undoubtedly the worst enemy to Melons, hundreds or perhaps thousands of plants being annually ruined by it. As I have previously pointed out, the surest way to ward off this disease is to keep the soil near the stems perfectly dry, and this, as far as my experience goes, can best be done either by planting rather high or by enclosing the stems with the aid of earthenware collars and glass to fit, as used by Mr. Pettigrew at Cardiff Castle. The plan adopted by Mr. Payne at the Wells Palace Gardens is also worthy of a trial. In this case the collars are actually buried. Mr. Payne informs me he has never lost any plants since he first tried this preventive measure, and others who may have tried it will perhaps give their experience. This may again be referred to at a more seasonable date, and I will now suggest what should be done with plants already affected by canker. During such a season as we are now passing through, or at any time when there is a sudden change from hot to dull weather, the collars and stems of the Melon plants ought to be examined once or twice every day, as a few hours' neglect may mar everything. Directly a wound is found with viscid matter oozing from it the latter should be cleanly scraped off, the sponge next applied, followed by repeated dressings with the quicklime or cement. It is quite useless to apply either silver sand or flowers of sulphur, as these are not at all caustic, and aggravate rather than remedy the disease. Nor is lime that has long been slaked or exposed to the atmosphere sufficiently effective. It must be either newly slaked or scraped from an unslaked lump. Half measures are quite useless, and unless the wound is thoroughly scraped clean and all decayed portions of the stem cut away healing will be out of the question. One of our heaviest cropped plants suddenly flagged badly, and as this was the first symptom of canker seen this year it had gone almost too far to cure. I found it necessary to cut clean through the centre of the stem, the very pith being decayed. The wound was scraped clean, dried, and dressed with quicklime, the plant also being shaded overhead. Strange to say, the healing was complete, and we had a double stem, which served to perfect the crop. Affected plants ought to be lightly shaded from bright sunshine, and also receive rather less moisture at the roots till such times as the cure has been accomplished.—W. IGGULDEN.

A WEEK'S WANDERINGS.

SWANMORE PARK.

A GOOD deal may be seen in a week when the weather is favourable, but as during the short period under notice every other day was rainy, we were about half the time dodging the showers or resting. Our first halt was at Swanmore Park, in respect to which we once heard the lucid remark, "As Molyneux has nothing else to do but grow Chrysanthemums, and as somebody else grows them for him, he ought to win prizes." If we attempt to analyse that sentence we find ourselves involved in a curiously mixed paradox, for if "somebody else" finds all the knowledge and manipulation that produces the prize blooms, it is *not* Mr. Molyneux who ought to win prizes, but the mysterious man behind him; and if Mr. Molyneux has nothing else to do but what another person does, his duties must amount to nothing at all. Mr. W. H. Myers is a great lover of his garden, and one of the best of masters to his men; but he does not pay them for doing nothing. Judging by the appearance of his estate he is well served, and the good all-round work seen in his garden could not be done except by a competent and industrious man devoted to his charge. Mr. Molyneux was once in a "single-handed" place, and when there won one of the finest silver medals ever offered for a collection of Grapes at Manchester. So it would appear he could do something when he had nobody to help him, and he can do something still. Besides having a good grasp of the principles of gardening, and not lacking in the useful commodity of common sense, he possesses what the late Lord Beaconsfield considered one of the greatest elements of success in life—persistence of effort. Mr. Molyneux is not the man to count hours, but early in the morning and late at night he is on the spot when anything requires to be done, and, as one who knows remarked, "if he thought there was an earwig among his flowers in the autumn, he would not go to bed till he caught it, and many a night in the showing season he has had no bed at all." Proceed

on right lines, then success is the outcome of attention to small details and persistent work.

The Swanmore Chrysanthemums are looking well this year, the majority of them perhaps better than usual, but there is a very instructive minority not looking so well. It is an experimental year chiefly with various manures. Fifteen different kinds, or compounds, are on trial, a certain number of plants being devoted to each, and as the varieties are grouped together the effects of the fertilisers are very apparent now. The trials will be carried out to the end let the results be what they may, and if there are good blooms at the right time they will probably find their way to some of the shows. Acquiring information, however, possibly for a future edition of the Chrysanthemum book, appears to be regarded as of more importance this year than concentrating resources in the production of blooms for exhibition. Wonderfully sturdy and vigorous are rows of Edwin Molyneux and Avalanche, the plants about 2 feet high, and stems as thick as a man's thumb. The tall growers, such as Belle Paule, Lord Wolseley, and others of the same habit, are from 6 to 8 feet high, and not frothy; the Queen family are from 5 to 6 feet high, with stems thickening out at the base and foliage clothing them to the ground; the leaves not "black," large, and flimsy in character, but stout in texture, and of a bronzy-green hue. "Not much the matter with them," the grower thinks. The chalk water and dry atmosphere on the breezy hill on which Swanmore stands have induced premature wood-ripening during previous hot summers, and to that is attributed the too narrow florets of several of the blooms; but there was no mistaking their solidity, depth, and high finish. This year the growth is ripening more steadily, and if increased size is imparted to the blooms, and their other characters are maintained, they will, to employ the showmen's phrase, "take some beating." That is enough on Chrysanthemums, and we will now step inside and see whether Mr. Molyneux has anything to do besides growing those plants.

A gardener has only to be a moment in the vineries to be satisfied that the Grapes are as good as the Chrysanthemums, especially in the late and Muscat houses, the Black Hamburgs not appearing to have recovered so well from the lifting, though they are bearing fruit of good quality. The roots in the inside borders were raised last autumn in all the houses, and it is astonishing how well the Vines in the two first named have done. The crops are splendid, those of Gros Guillaume and some Muscats remarkable, while better bunches of Mrs. Pince have rarely been seen; they resemble some fine examples I remember at Longleat, and others at Abberley as grown by Mr. A. Young last year. But the most imposing bunches at Swanmore are of Gros Guillaume. The Vine is pruned on the close-spur system, yet appears to bear as freely as the Black Hamburg. The bunches, weighing from 5 lbs. to 7 lbs. each, hang at regular intervals from the bottom to the top of the Vine. How many cannot be remembered, but they will probably weigh in the aggregate 50 lbs. or 60 lbs. They are of excellent shape, and the berries are as fine as the bunches. The Muscat bunches, in the house devoted to that prince of Grapes, are full, heavy, shapely, with berries large and uniform. It is noticeable in those houses that the finest bunches hang from the lower half of the roof, some of the largest being quite at the base. This denotes good culture. "Big bunches" are frequently enough seen near the top of Vines, but dwindle down as the base is approached.

The Swanmore vineries are large and light, with hot-water pipes distributed at 4 or 5 feet intervals from the front to the path at the back, not piled all together next the front wall. The plan is undoubtedly good, and the Vines show they are suited. The borders are mulched with manure, roots bristling through the soil, and are treated to a supply of "Thomson's," which the Vines seem to relish. The laterals are thinly disposed, there being no crushing or crowding of the leaves, and they are allowed to extend as far as there is room for the development of the foliage and no farther—undoubtedly a common sense method of procedure. There has been no mistake in ventilation, no inrush of cold air through the front sashes early in the season, as if that had been permitted no such Grapes would be seen near the base of the roof. Front ventilation is indispensable at the right time, but is seriously abused in many houses to the detriment of the Vines and crops. Madresfield Court is well grown, the bunches not large, but berries good and well finished without cracking—an evil that can be averted by a proper system of ventilation. It is an excess of atmospheric rather than root moisture that is the most active agent in the cracking of Grapes. The grower of the Vines referred to has quite as much reason to be satisfied with them as he has with the Chrysanthemums outside, for he really has something to do with both, giving to them close personal attention.

We pass on in the same fine range through a gay plant house, in which the good old *Trachelium coeruleum* is seen to advantage, also Brugmansias, then enter a stove full of specimen Crotons and other plants getting too large for the space, with Stephanotis growing luxuriantly overhead, and which flowers abundantly; also pass in a vinery a number of Eucharises flowering for the third time this year; then in another house come to a blaze of Tuberous Begonias, the plants admirably grown, pausing in a Peach house to admire a Pine Apple Nectarine tree that can have few superiors. It nearly fills a house 30 feet long, the trellis being 13 feet wide, and is carrying a crop of about 500 fruits, regularly disposed from the base to extremity of the branches, and swelling to a very large size. It is a young tree, and as an example of culture is equal to the best Chrysanthemums ever grown. Table and room decorative plants are grown extensively and well, these being more acceptable for their purpose by the "surface plants," such as Fittonias, Pileas, Panicums, and others that are suitable growing in the pots, these having a much better effect than moss packed

on the soil. Melons and Cucumbers are grown with these plants, and it is astonishing how much is done with the limited space suitable for growing various kinds of plants.

The shrubberies are well stocked with a choice assortment of deciduous trees, Conifers, and evergreens, and lawns and walks kept in the best condition. A group of the Golden Elder and Purple Nut (Corylus) at the entrance is particularly effective, the former being cut back yearly, and in July the green points are picked from the young growths, the bushes themselves being a mass of clear yellow. It is surprising how greatly they are improved by the simple process of pinching in the summer. The most effective flowering shrub a fortnight ago was *Philadelphus grandiflorus*, densely covered with flowers much larger, purer, and less powerfully scented than those of the old Mock Orange, *P. coronarius*. The large-flowered variety might be planted more freely with advantage to the appearance of pleasure grounds in summer. The flower garden is rendered cheerful by variety—hardy herbaceous plants, subtropical mixtures, and carpet bedding being well represented. Tuberous Begonias are also remarkably well grown in masses, the beds surfaced with *Sedum glaucum*. This has a very neat appearance, and contrasts well with the rich flowers above, while it prevents the soil being dashed upon them during heavy rains, and arrests evaporation in hot weather, but in that respect was more useful last year than this. A rockery dell made a few years ago is now furnished, and is a charming feature of the grounds. It is worthy of description, but this cannot be given at the present time.

The crops in the kitchen garden are too luxuriant, the wet weather and strong soil forcing them out of character. The Red Currant bushes are worthy of special note. Six or seven branches have been chosen and summer-pinchd as cordons; these extending some 6 feet long are densely clustered with fruit their whole length, and as there is a clear space of a foot or more between them, the crop is quickly and easily gathered. Gooseberry bushes are borne down with fruit, as usual, and are seldom pruned, but the bearing branches are thinly disposed, and the fruit is taken off in handfuls. It is not too much to say that everything attempted indoors or out is done well at Swanmore, and beyond the gardens Mr. Molyneux has planted about 250,000 trees during the past three or four years, so it will be apparent he has something else to think about and attend to besides Chrysanthemums. His assistants work under his personal instructions in all the departments, hence he holds himself responsible for the failure of whatever may be in hand, and correspondingly he must be credited with the success achieved, though he does not hesitate to speak approvingly of the good and willing services of his helpers. All appear to work well, cheerfully, and happily at Swanmore. It is felt that the head of all deserves their best efforts, as he is generous, appreciative, and kind.—A WANDERER.

BLUE GUM TREES.

THE remarks of "F. H." at p. 77 in reference to the Blue Gum of Australia (*Eucalyptus globulus*) not being often met with in a flourishing condition planted out of doors in this country, induces me to say that one is growing in a border and trained up the wall of the south part of the Hotel Ilfracombe, in the picturesque seaside town of that name. The tree occupies a central position, is from 30 to 40 feet high, having a large trunk and a good spread of luxuriant foliage. I have also noticed several other Blue Gum trees of smaller size in different parts of Ilfracombe, and, if I remember rightly, in the village of Clovelly, ensconced on the face of a steep chasm in the seacoast 23 miles thence and 10 miles from Bideford. But if your correspondent will refer to the Journal for June 16th, 1887, p. 482, he will find that there is a much larger specimen than the one recorded above in the beautiful grounds at Whittinghame, Prestonkirk—nearly 600 miles farther north—and which is probably the largest *Eucalyptus* in Great Britain. The dimensions are—trunk, 10 feet 4 inches in girth; main limb, 5 feet; other two, 3 feet 7 inches each, and some of smaller dimensions; height, 60 feet. It may not be out of place to state that the soil at Whittinghame overlies the old red sandstone formation, the subsoil being mostly of sand or gravel; the atmosphere is consequently dry, and to this fact is attributed the immunity from severe frosts, and frost does not do the same amount of damage as it does in low-lying districts, where the air is more moist. Whittinghame is but a few miles from the German Ocean, its elevation being about 320 feet above sea level.—H. W. WARD.

HUMEA ELEGANS.

THIS half-hardy biennial is of graceful habit. It attains a height of 5 or 6 feet when well grown, the large fragrant leaves and feathery inflorescence being very telling in a border, the centre of a mixed bed, or mixed with less tall-growing plants on the centre stages of greenhouse or conservatory. The seed should be sown at once in a 6-inch pot or small pan filled with sandy soil. Cover lightly, water, and place on a shelf in the greenhouse with a piece of glass and a little moss over it. As soon as the little plants appear the moss should be removed. When large enough they should be pricked out in thumb-pots, one in the centre of each, using a mixture of light sandy loam and sweet leaf mould, three parts of the former to one of the latter; water through a fine rose. Place them near to the glass in a cold frame. Shade and keep

close until the plants have recovered from the slight check which they experienced through having their roots disturbed. Afterwards they should be shifted into larger pots, as they require more room at the roots, and be grown on in a position near to the glass in a dry airy greenhouse.—H. W.

SOBRALIA LEUCOXANTHA.

At a recent sale in Messrs. Protheroe's Rooms, Cheapside, a plant of *Sobralia leucoxantha* from Messrs. Seeger & Tropp was sold for 30 guineas after a very spirited competition, "thus showing," as a correspondent remarks, "that good Orchids realise full value." This *Sobralia*, which is one of the most beautiful species in the genus, is very rare, and I have heard of but three good examples—the one recently sold, as already stated; a second, which is or was in the possession of Mr. Grose Smith, who is said to have refused 75 guineas for it; and a magnificent plant in Mr. R. H. Measures' collection at The Woodlands, Streatham. The last named has been flowering well this season, and its owner has kindly forwarded the

FIG. 10.—SOBRALIA LEUCOXANTHA.

flower from which the woodcut (fig. 10) has been prepared, but the drawing has been slightly reduced below the natural size.

In the flower sent the sepals were nearly 3 inches long and 1 inch broad, massive, pure white, and recurving. The petals were of similar length and breadth, slightly recurving, not quite so thick as the sepals, but very pure white. The lip is partially tubular, the tube 2 inches long, the limb rounded one-half to three-quarters of an inch across, and beautifully frilled, rich orange yellow in the throat fading to the margin, which is pure white; the base of the lip and the column are also white. The flower is very neat in form, the wax-like substance and purity being beautifully relieved by the dash of orange in the lip.

The plant is dwarf in habit, the slender stems 1 to 2 feet high bearing plicate leaves like those of other better known *Sobralias*, and the flowers are clustered near the apex of the stem. It is related to *S. macrophylla*, but must not be confounded with *S. xantholeuca*, also a rare, valuable, and handsome plant, bearing pale yellow flowers.

CATTLEYA SCHOFIELDIANA,

Also from The Woodlands, I am favoured with handsome flowers of this extremely distinct Cattleya, which in a genus remarkable for its variety of floral form and colours stands out very conspicuously. The flowers now on my table are nearly 7 inches in diameter across the outstretched petals, the diameter from the top of the upper sepal to the lower being nearly as much. Both series of divisions are of a peculiar tawny yellow freely dotted with crimson purple; the upper sepal over 1 inch broad, straight and erect, the two lower shorter, broader, and curved inwards. The petals are narrow at the base, undulated at the margin, and $1\frac{1}{2}$ inch broad towards the lip. The lip has two lateral white lobes closely folded over the broad yellowish column, the central lobe being 2 inches long, narrow at the base, yellow streaked with red, the apical portion an inch broad, densely covered with prominent crimson papillæ and irregularly edged with white. The flowers are borne in pairs, and possess a strong and rather heavy odour.

In the second volume of the "Orchid Album" (plate 93), Mr. B. S. Williams gave an excellent illustration of this Cattleya, prepared from a plant in the collection of G. W. Law-Schofield, Esq., New-Hall-Hey, Rawtenstall, near Manchester, after whom it was named by Professor Reichenbach, and at that time, 1883, it was believed to be the only plant in the country. It is evergreen, with terete stems 18 inches high, somewhat resembling both *C. amethystoglossa* and *C. Leopoldi*. The culture recommended by Mr. Williams is "rough fibrous peat good drainage, the plants well elevated above the rim of the pots, and the same temperature as *C. Trianae*."—L. CASTLE.

ORCHIDS AT FOREST HILL.

THE following Orchids are now in flower at Messrs. John Laing and Sons' Nurseries, Forest Hill, London, S.E.:—*Aerides odoratum*, *Brassia verrucosa*, *Cattleya Gaskelliana* and *gigas Sanderiana*, *Cypripedium barbatum*, *Roehli*, and *Sedeni*, *Dendrobium Pierardi*, *Dendrobium filiforme*, *Disa grandiflora*, *Epidendrum vitellinum majus*, *Galeandra species*, *Masdevallia Bonplandi*, *Lindenii*, and *Veitchiana*, *Maxillaria venusta*, *Odontoglossum Alexandræ*, *blandum*, *cordatum*, *crispum*, *Harryanum* (fine), and *Pescatorei*, *Oncidium incurvum*, *Jonesianum*, and *orientale*. There are also some good plants of *Utricularia montana* and *Endresii* in flower.

DEGENERATION OF FRUIT AND VEGETABLES.

[A paper read before the Massachusetts Horticultural Society by Mr. O. B. Hadwen, Worcester, U.S.A.]

(Continued from page 83.)

THE Cherry and Plum do not manifest a tendency to degenerate; they seem to suffer through injury from insect enemies rather than from any inherent morbid condition. The varieties grown by the earlier cultivators are still known and esteemed; manifesting, even under the influence of repeated engrafting and of artificial modes of cultivation, a decided tendency to long life. Cultural practices which seem to have impaired the longevity of the Pear and Peach apparently have little if any effect upon the Cherry and Plum, thus leaving the question of degeneration in these involved in considerable doubt.

Among the "small fruits" the Strawberry furnishes the clearest evidence as to its duration of life. Of this fruit, as nearly as I can recall, the kinds that have been cultivated thrive about thirty years; although there have been a few instances of longer duration, and some whose term has been shorter. Of twenty sorts grown by nurserymen and advertised fifty years ago, not one is known in cultivation, if we except the Alpine, which seems to be perpetual, as does also the wild or native Strawberry. Within the past forty years hundreds of varieties have been produced from seed brought into notice, and are now gone to give place to new seedlings; and but few now extensively grown have been known to cultivation twenty years. Of fifty-one varieties grown in the nurseries of the late William R. Prince in 1839 not one remains. The Strawberry reproduced from runners gradually becomes enfeebled and unproductive and passes away, giving place to new and vigorous kinds raised from seed, which seems to be Nature's mode of reproduction. The Raspberry, Blackberry, and Currant are long-lived, and sorts that were grown as far back as the memory of man runneth are as good now as ever, conditions being equal. New seedlings are brought out from time to time, which, as novelties, have a tendency to supplant the older sorts, but the Antwerp, Franconia, Falstoff, Knevett's, and Northumberland Raspberries, and a dozen others are just as good as ever. Neither do the Blackberries or Currants, when well grown, give much if any evidence of degeneration; when they fail it may fairly be attributed to the influence of poor soil and cultivation.

Vegetables, especially those annually grown from seed, cannot degenerate; seeds may become mixed and new sorts may be produced, but the annuals cannot be classed among plants that degenerate. Some seasons are found unfavourable to the development and growth of certain kinds; and new sorts are continually being introduced and tried. The Potato, indigenous to the mountainous sections of Mexico and South America only, is consequently, when cultivated here, far re-

moved from its native home, and it affords us the best illustration of the importance of renewal by seed. As usually propagated from the tuber, it grows and thrives well for about twenty-five years, after which it manifests a very decided tendency to degenerate; and new seedlings are resorted to, which in their turn will last a given time, and produce good crops. Within my own experience, I have grown the Black Rusty Coat, Long Red, Chenango, Rohan, Peach Blow, Carter, Jackson White, Dover, Davis's Seedling, Kidney, State of Maine, Early Rose, and Hebron, with several other sorts, but only two of all these are now cultivated.

To attempt the inquiry into the growth, longevity, and decay of the fruits and vegetables we cultivate—to seek to learn the natural principles involved in the growth of each species, and the laws and principles of decay belonging to each, is particularly difficult where each seems to be governed by different and intricate forces pertaining to its peculiar organism. Nature, with man's assistance, has produced fruits and vegetables in wonderful variety and profusion and of the highest excellence, and is still pressing onward; every season brings some new success in the line of fruit or vegetable raising, and notwithstanding there is so much mystery clouding the whole subject—so much that we should know but do not—so much guesswork, instead of positive information, and so much that seems impossible for the mind to understand peculiar to each plant. Nevertheless, it appears worth our while to discuss these questions with the hope of new and increasing light pertaining to the philosophy and science of horticultural and pomological pursuits. There can be no end to horticultural investigations; and few if any conclusions in this hidden science can be considered final; and the subject we have been discussing still affords a wide field for inquiry.

The conclusions which I have been led to regard as provisionally established may be summarised as follows:—

First, Each fruit-bearing tree and plant seems inherently endowed with a certain given period of life; this, however, is subject to be influenced by favourable and unfavourable conditions.

Second, Each species and variety of fruit-bearing tree and plant seems governed by conditions pertaining exclusively to its growth, maturity, and decay.

Third, Some fruits appear to degenerate, while others furnish but little evidence of deterioration; and the latter statement applies equally to vegetables as a class during this century.

Fourth, While there undoubtedly is a limit to the life of every plant and fruit, neither science nor philosophy has yet determined the data by which we can deduce with any degree of accuracy the duration of life of any of the larger fruits or vegetables.

The subject, as regards each fruit, seems to be governed by separate laws and conditions; and where such infinite variety exists it renders equally limitless the extent of possible inquiry, and opens a wide field for experiments and experience; and also may be prolific in topics for discussion.

Mr. Charles M. Hovey was called on by the chair, and said that the subject had been treated by the essayist in a very able manner, and that it deserved the thought and attention of the members of the Society. That fruits degenerate we very well know, but whether from unfavourable climates or from other causes is not settled. The old varieties of Peaches are still in perfection in England; within a week he had seen the Grosse Mignonne and George the Fourth recommended for cultivation as among the best varieties there. Of Strawberries the Keen's Seedling, introduced in 1821, and the British Queen, originated about forty years ago, are still favourite varieties, though the latter is not suited to our climate. The Hovey's Seedling and the Boston Pine were raised by the speaker in 1833, and in his ground still give as good crops of fruit as ever. The Wilson, which has been more widely cultivated than any other variety, is still very good. We cannot raise the Flemish Beauty and Easter Beurré Pears; they have degenerated here, but in California they are as fine as ever, and whether their degeneracy here is inherent in the variety is the question. Mr. Knight's opinion that every tree propagated from a seedling, being a part of that tree, perishes when the lifetime of the original tree expires, has been proved fallacious. The trouble is that the lifetime of one man, or even two, is too short to make reliable observations on this subject. Men must take it up in succession, if possible, but hitherto they have not done so, and the result is that we are continually beginning, and never come to any certain conclusions on the subject.

Grafting is undoubtedly sometimes injurious, the stock and scion do not seem to be congenial. Many varieties will not succeed on the Quince stock; with the speaker the Glou Morceau and Duchesse d'Angoulême flourish; and some of his trees have sent out roots from the Pear, while others have not. He could see no degeneracy in Pears except in a few varieties, such as the White Doyenné, Flemish Beauty, and Easter Beurré.

We can remember when we picked up the delicious Peaches under the trees, but we do not remember how many seasons there were when the crop failed. He had been out among his Peach trees and shaken them when the fruit almost seemed to fall into his mouth; for six or eight years he got a crop one year out of two. He had read much on this subject and had been a pretty careful observer, and had come to the conclusion that to explain degeneracy we must not look for causes inherent in the variety, though perhaps this may exist to a certain extent in some, but to other causes, climatic or residing in the soil.

To the question whether grafted trees ever go back to inferior varieties he answered, No. He felt doubtful as to the influence of the

stock on the graft, but he admitted the existence of sports. The Lewis, one of our native fruits described in the "New England Farmer" many years ago by Samuel Downer, senior, is a very nice Pear, but too small and green, and he grafted a tree of that variety with Bosc. Afterward he noticed on another Bosc tree some small green Pears growing on a graft; which some persons might have accounted for by the influence of the stock, but inquiry showed that the grafts used on this tree had been taken from the first mentioned Bosc tree, and some had been carelessly cut from Lewis suckers below the graft.

(To be continued.)

ROSES IN WET WEATHER.

OWING to the long-continued wet and sunless weather large numbers of Roses have failed to open their blooms properly. When on the point of expanding, the outer petals commence to decay, and in the majority of instances no further progress is made. There are, however, a few noteworthy exceptions to the rule, the best of these being the Countess of Oxford. We never had this generally serviceable Rose finer or in better colour, and as it strikes more readily than other varieties with thorns, another large batch of cuttings will be put in next autumn. La France both on its own roots and budded on the Briar stock has given us many extra fine blooms, these being borne on rather thin growth, drooping somewhat, and thereby escaping injury by rains. Souvenir de la Malmaison, a well known Bourbon Rose which is easily struck and thrives best on its own roots, has yielded a continuous supply of good blooms, and will continue to do so till cut down by frosts. Cheshunt Hybrid against walls, also as standards and dwarfs, never was more floriferous with us, and the greater portion of the blooms were sound and fresh in colour. It is very sweet scented and, on the whole, one of the best Roses in cultivation.

Baroness Rothschild, although very different from any of the preceding as regards style of growth, being of stiff erect habit, has yet given us many very handsome blooms, and which have not been discoloured so much as might reasonably have been anticipated. The white form of it or Merveille de Lyon, has been a failure this season. The richly coloured Duke of Wellington on tall Briar stocks has not been injured by rains. Charles Lefebvre has done good service both as standards and its own roots, and we have cut numerous good blooms from dwarf blooms of the Duke of Edinburgh. Etienne Levet on its own roots has done remarkably well, in fact this showy variety never fails. The beautiful Madame Gabriel Luizet has passed through this most trying season better even than usual, and we have had many perfect blooms of it. Jules Margottin has done fairly well, and so also has the Comtesse de Chabillant. The greatest failures were John Hopper (usually very serviceable), Captain Christy, Madame Eugène Verdier, John S. Mill, E. Y. Teas, Mrs. Baker, and Xavier Olibo, the blooms on these either refusing to unfold or else being badly discoloured. There is one bright side to the picture—viz., a good prospect of many fine late blooms being formed, more especially on the dwarfs. Numbers of these have pushed up long and fairly firm shoots, furnished with a cluster of buds at the point, which if duly thinned out should be invaluable for the August shows. La France, in common with Catherine Mermet and other Teas, has developed strong branching suckers which will produce a long succession of fine blooms. Last season very few succeeded in establishing many Roses on the Briar stock, neither the buds nor the stock "running" properly. This year the reverse is the case, the merest tyro being able to bud successfully, and in all probability will be able to do so throughout the month of August. We rather prefer budding late, as in this case the buds are dormant till the spring, when they break more strongly than do those that made a slight start the season they were inserted.—W. I.

ROSES IN WINTER.

I WISH to return my thanks and express my obligations to you, and through you to Mr. Bardney, for the excellent and creditable replies to my queries of 12th inst. *in re* Roses in winter.

Mr. Bardney seems to doubt my being a "learner," and that some of my queries implied doubt as to some statements he had previously made. Now, though I have been a diligent reader of "our Journal" for eighteen years, and practised as much of its unequalled teaching as lay in my way, yet I am strictly but a "learner" in this matter, and had not the least doubt of anything Mr. Bardney advanced, but followed even the large pots for my new Roses this spring, even though it was quite new to me to use such large ones. If a "learner" might be allowed to offer an opinion, I consider these papers—more particularly this last—of Mr. Bardney's excellent, and worthy of "our Journal."—S. S.

TIBSHELF.—JULY 24TH.

"TALKING about prizes, have you seen the Tibshelf schedule? Why, there are £6 for seventy-two, seven prizes for forty-eight, a class of eighteen for amateurs, and a class for twelve Teas." These words formed

part of a general conversation in a Rose Show tent in the early part of the season, and were followed by divers inquiries of "What is Tibshelf?" "Where is Tibshelf?" and even, "Who is Tibshelf?" And, though geographical knowledge as to the locality seemed at that time to be very scarce, it was evident on the morning of July 24th that a good many rosarians from all parts of England had written to the courteous Secretary, Mr. R. Harrison, and had found their way to the place with goodly piles of boxes.

Tibshelf is a colliery village on the borders of Derbyshire, of about 2200 inhabitants, and, although the Roses occupied only four among nearly 200 classes, and the prizes ranged from £10 down to a steel spade, it was an extraordinary exhibition even viewed as a Rose show alone, and offered some food for meditation to those who know how large and wealthy towns make a fuss about offering £4 or £5 as the principal prize for Roses. If, perchance, any rosarian thought he had "discovered" Tibshelf, that the competition would not be strong, and that, with seven prizes in one class, one could not well be "out of the money," in such a case I fear there may have been some disappointment, for the competition was very keen indeed, and it was easy to be prizeless in any class. Now, please let all Rose Societies take note of this. At a little, comparatively unimportant, place like Tibshelf, there were staged eight stands of seventy-two as against five at the National Rose Show at the Crystal Palace, sixteen of forty-eight as against thirteen in two separate divisions at the Palace, six of eighteen (amateurs), and six of twelve Teas (open). Please take note of that. And if you want to insure to your visitors a grand sight of the best Roses to be seen that day in England, have big classes, good prizes, and plenty of them.

In the class for seventy-two blooms, first honours—a prize of £6 and the gold medal of the N.R.S.—were carried off by Mr. B. R. Cant of Colchester, after an exceedingly close contest, Messrs. Harkness & Sons of Bedale, Yorkshire, running him very hard indeed. Mr. Cant had the finest and "heaviest" H.P.'s in his stand (I heard the word "heaviest" applied to them, but hardly think it a happy term to use for best blooms), but he had somewhat of a "tail," which was carried, if he will forgive me, too much like a tail—viz., all at one end. Messrs. Harkness had a more even collection, their smaller H.P.'s being more in the middle, while their exhibit was wonderfully heightened by no less than twenty-two of the best Teas I have seen this season. A noticeable flower in Mr. Cant's stand was a very large "heavy" bloom of Baron Haussmann, while almost all the Teas of Messrs. Harkness were worthy of admiration. Mr. Frank Cant was third with a good stand. It should be noticed that there was an unfortunate, but very natural, misunderstanding as to the conditions of this class. The schedule—a wonderful thing in its way—said, "Seventy-two blooms, varieties," which was interpreted by the authorities to mean not necessarily seventy-two distinct varieties. The leading competitors had come prepared to show seventy-two distinct, so there were not so many duplicates as there would have been if this unusual arrangement had been known beforehand: but it was rather hard upon one or two, who did not hear of this till within a short time of the judging.

Sixteen stands of forty-eight distinct varieties! I think there was one which at the last moment did not come up to the scratch; but, even then, surely a class of fifteen forty-eights has seldom been equalled. They formed a wonderfully long line for the Judges to inspect, and a somewhat unusual order of merit followed. Rev. J. H. Pemberton of Havering-atte-Bower, Romford, was clearly first. He was evidently in good form, and able at last to hold his own with anybody. His H.P. blooms had wonderful size, substance and solidity. Messrs. R. Mack and Sons of Catterick, Yorkshire, the raisers of "Sir Rowland Hill," were second; and it was noticed that there was a bloom of this fine new Rose in Mr. Pemberton's stand, but not in theirs. Rev. A. Foster-Melliard, Sproughton Rectory, Ipswich, followed quite closely as a good third. Mr. Frank Cant was fourth, Messrs. Harkness fifth, and Messrs. Perkins & Sons of Coventry sixth. The seventh prize box had no name on the card while I was there, but I was told it belonged to Mr. W. J. Grant of Ledbury, Herefordshire. The remaining exhibits were some distance below the high standard which Mr. Pemberton had set to the class.

There were six competitors in the class for eighteen Roses (amateurs), and here Mr. Grant was first, having evidently reserved himself for this class. Mr. Pemberton was a good second, but I could not ascertain the name of the third. In the open class for twelve Teas or Noisettes there were also six stands shown. Messrs. Harkness were deservedly placed first, their blooms being fresh, clean, and of a good size. Mr. Frank Cant, who also has protected his Tea Roses during the wet season, and thereby contributed largely to his successes, was a good second, and Rev. A. Foster-Melliard third. The latter gentleman also contributed an extra box of twelve blooms of Comtesse de Nadailae, which received an *he* card. With such a large number of exhibits the local authorities very wisely availed themselves of the presence of so many of the leading professionals and amateurs by setting them to judge each other, as is done at the N.R.S. exhibitions. It was thus done expeditiously and satisfactorily.

Of the many other things to be seen at the Tibshelf Show I cannot ask for space to enumerate even those which were really worthy of mention. The very tickets of admission were gaily coloured cards, representing all the world and his wife in miniature on the way to the Tibshelf Show and Gala. I know there were all kinds of horticultural exhibits for all classes of people: flowers, fruit, vegetables, Wheat, Barley, Oats, and Turnips, wild flowers, butter, and honey; nigger entertainments, athletic sports, and the band of the Grenadier Guards;

for I saw all these. And I believe there were pigs, for there were classes for pigs in the schedule. For those in a pig club (What is a pig club?), and those not in one; for those who fed their pig with spice—dainty epicurean pigs, no doubt, and for those who fed him with powders. I rather wish I had seen the powder-fed one. I should have expected "somewhat of a tail" again. But I did not see any of the pigs; they were not in the Rose tent at all events.

But there was one class in the Rose tent for which a word must be said. "Class 122, group of plants arranged for effect, to cover about 155 feet." Seven prizes commencing with £10—£34 in all. Well done, Tibshelf! The exhibits in this class occupied the whole of the centre space in the large circular tent, round which the Roses were disposed. It has always seemed to me that it must be unsatisfactory to exhibit in any line where there is no strictly defined standard, and where competent Judges may have different ideals; but this would apply to all classes for decorations, and even to bouquets, and, as nobody seems to grumble, I suppose it is all right. The name, without any address, on the card belonging to the first prize group was Mr. Hacker. I should have thought this arrangement was rather heavy; the colouring seemed to be derived almost entirely from foliage and to have too great a preponderance of yellow. I preferred the group which was labelled fourth prize, Mr. Lyon's, as being lighter in general effect and showing a better arrangement of space and distance. But I daresay there are some "rules of the game" which I do not understand.

The day was showery, but I hope it improved in the afternoon after we left, and that the attendance was sufficient to repay the trouble expended, for we were all most hospitably entertained with breakfast, luncheon, and all we could want, and left the place with a very high opinion of the cordiality, pluck, and enterprise of the Colliery Club and Horticultural Society of Tibshelf.—W. R. RAILLEM.

LOUTH.

THIS Show was held in the Town Hall on July 25th, and was in every respect a highly successful one. The number of exhibits gathered together, when the adverse season for Roses is taken into consideration, was astonishing, and the excellence of the blooms was the subject of general remark. The number of cut Roses exhibited was 868, exclusive of the Roses used in designs, decorations, bouquets, and baskets, and there were fifty-seven boxes of flowers. The arrangement of the exhibits left nothing to be desired, and the Hall was prettily decorated. Hundreds of Ferns and plants in pots had been kindly lent and arranged by Mr. George Moody, with the most pleasing effect, and Mr. H. Norton also lent a number of Ferns for decoration. In the front of the orchestra there was an effective device, in Roses on a background of moss, "Success to the Louth Rose Show," which must have taken Messrs. H. Clark and North many hours to arrange. It contained upwards of 300 Roses.

Messrs. Harkness & Sons of Bedale, Yorkshire, were given four first prizes, including the premier honour for Horace Vernet, the best bloom in the Show, and their success was well deserved. Mr. H. Norton of the Rose Nurseries, Louth, was also well to the front, and the fact of his taking prizes in such good company showed the excellence of his specimens. Messrs. Burch of Peterborough were well represented, and the specimens from Cambridge were very fine.

Amongst the best blooms in the Show there were the following in Messrs. Harkness & Son's collection: Horace Vernet, a splendidly built up flower, very dark and with very shell-like petals. This flower deservedly won the special prize for the best bloom in the Show. Other good blooms were Her Majesty, Etienne Levet, Antoine Ducher, Captain Christy, Ulrich Brunner, A. K. Williams, a well made flower; Catherine Mermet, a very handsome bud; and Heinrich Schultheis. In Messrs. Burch's stands the following were very good: Abel Carrière, a very dark bloom and very catching; Duchesse de Morny, Lady Mary Fitzwilliam, Ulrich Brunner, Alphonse Souper, Duke of Connaught, Her Majesty, A. K. Williams, Dr. Sewell, Eli Morel, beautiful; and Horace Vernet. Messrs. Burch were awarded a special extra prize for Roses. In Mr. Norton's stands these were most excellent—viz., Alfred Colomb, Duke of Wellington, Etienne Levet, Magna Charta, Grace Darling, A. K. Williams, Lord Macaulay, Madame Chas. Wood, Ulrich Brunner, a very fresh bud, which won a special as third best in the Show; Pride of Waltham, La France, Merveille de Lyon, Comtesse d'Oxford, and Dupuy Jamain. In Messrs. Burrell's stands were capital examples of Lady Mary Fitzwilliam and Comtesse de Nadaillac, a lovely Tea which won second best special. Mr. Ismay Fisher had La France, Magna Charta, Catherine Mermet, and Her Majesty in very fine form. Dr. Clegg, Boston, had a good Ulrich Brunner. The quality of all these Roses, considering the very showery and boisterous weather of the previous day, was really very good.

There was only one bouquet, but it was a lovely one, shown by Messrs. Burch. The baskets of flowers were very beautiful, and Mrs. Chas. Dickinson was deservedly awarded premier honour. The class for designs by ladies elicited something novel and pretty. The first prize design was an artist's easel, by Miss Chatterton, of Hallington, which was complete with rest, palette, and brushes, and the picture consisted of the beautiful flowers of which it was composed. Miss Holland's submitted a well-formed model of a ship's anchor, with a chain of Feather Feu. Miss Lucas's design was a rustic style, very pretty and ingenious, made up of flowers, Ferns, &c. The only boxes of Roses not for competition were those forwarded by Mr. Cheney Garfit of Kenwick Hall. The President of the Society (W. H. Smyth, Esq.), and other gentlemen had intended to supplement the Exhibition, but the stormy weather had completely destroyed the value of their specimens.

We cannot close our comments upon the Exhibition without a word of praise for Mr. A. James, whose efforts had attained a success which exceeded the most sanguine expectations. The amount of work passing through his hands must have been prodigious, and we were glad to see that in the arrangement of the exhibits he had the benefit of the experience of Mr. W. Walkington. There appeared to be a unanimous desire that the event should become an annual one, and doubtless this expression of opinion will receive due consideration at the hands of Mr. James and the Committee of the Louth Rose Society.

The following is a list of prizes:—Open to all comers.—Class 1.—Thirty-six varieties, distinct, named: first prize, £3; second, £2; third, £1; £6.—First, Messrs. Harkness & Sons, Bedale, Yorks; second, Messrs. G. & W. H. Burch, Peterborough; third, Mr. H. Norton, Rose Nurseries, Louth; fourth 10s., Messrs. Burrell & Co., Cambridge. Class 2.—Twenty-four varieties, distinct, named: first prize, £2; second, £1; third, 10s.; £3 10s.—First, Messrs. Harkness & Son, Bedale; second, Messrs. Burch, Peterborough; third, Mr. H. Norton, Louth. Class 3.—Twelve Tea or Noisette, distinct, named: first prize, £1; second, 10s.; third, 5s.; £1 15s.—First, Messrs. Harkness & Sons, Bedale; second, Messrs. Burrell & Co., Cambridge; third, Messrs. Burch, Peterborough. Class 4.—One bouquet, with own foliage: first prize, 5s.; second, 3s.; third, 2s.; 10s.—First, Messrs. Burch, Peterborough. Only one entry. Class 5.—Best bloom in the Hall, selected from any stand: first prize, 5s.; second, 3s.; third, 2s.; 10s.—First, Messrs. Harkness & Sons, Bedale; second, Messrs. Burrell & Co., Cambridge; third, Mr. H. Norton, Louth.

Open to county of Lincoln only.—Class 6.—Thirty-six varieties, distinct, named: first prize, £2; second, £1; third, 10s. First, Mr. H. Norton, Louth; second, Mr. Ismay Fisher, Scawby, Brigg. Class 7.—Twenty-four varieties, distinct, named: first prize, 30s.; second, 15s.; third, 7s. 6d. First, Mr. H. Norton, Louth; second, Mr. Ismay Fisher, Scawby. Class 8.—Twelve varieties, distinct, named: First, Mr. H. Norton, Louth; second, Mr. Walter Clegg, Boston; third, Mr. Ismay Fisher, Scawby.

For amateurs only within fifteen miles of Louth.—Class 9.—Twelve varieties, distinct, not named. First prize, Major Allott, Louth; second, Mr. R. Chatterton, Stenigot; third, Mr. W. Wood, Cemetery, Louth. Class 10.—Twelve, any variety, not named. First, Major Allott, Louth; second, Mr. Wood, Louth Cemetery; third, Mr. R. Chatterton, Stenigot.

For lady competitors only.—Class 11.—One basket of Roses, any variety, own foliage. First, Mrs. Chas. Dickinson, Louth; second, Mrs. H. Clark, Louth; third, Miss Chatterton, Hallington. Class 12.—Best floral design of Roses, with Ferns or any other dressing. Any other flowers may be added. First prize, Miss Chatterton, Hallington; second, Miss Holland, Louth; third, Miss Lucas, Louth. For cottagers only.—Class 13. First, Mr. George Dobson, River Head, Louth; second, Mr. Stamp, Broadbank, Louth; third, Mr. Thos. Wilson, Cawkwell.

ROSE SHOW AT THE PAXTON SOCIETY, WAKEFIELD.

THE annual Rose Show was held in connection with the Paxton Society, when, notwithstanding the unfavourable weather which has prevailed for some time past, and which has considerably interfered with the cultivation of the Rose and other flowers, there was a very large and magnificent display of Roses of many different varieties of form, colour, and scent, and they were much admired by a large gathering of the members and a number of visitors. The blooms were very tastefully arranged and displayed in a large, varied, and beautiful collection of vases and stands by Councillor Lupton, the energetic and genial curator, at whose house (the "Saw Hotel") the meetings have been held since the formation of the Society. Councillor Milnes, the President, was in the chair, and Mr. Brown, gardener at Hatfield Hall, occupied the vice chair. Mr. George Bott of Walton, who is a noted and very successful Rose grower, not only exhibited a large and fine collection of Roses, but he also read a very able and exceedingly interesting and instructive essay on the Rose, to the growth and improvement of which he devotes special attention, and with regard to which favourite flower he has on several previous occasions furnished essays.

Mr. Bott styled the Rose the flower of flowers, the queen of flowers, and said that whatever virtue any other flower possessed it was found in the Rose, which is the emblem of everything that is sweet and lovely, and the representative flower of the greatest nation on the face of the earth. He pointed out that the Rose is of a much more accommodating character than is generally supposed, and said that many people were deterred from growing it because they thought the soil in their gardens unsuitable. He advocated the liberal mulching of the ground with manure in autumn, and said that if this was carried out Roses might be grown in almost any soil. Roses should be freely, carefully, and judiciously pruned; if they spared the knife they would spoil the tree. To get rid of such pests as maggots, caterpillars, and green fly he recommended hand-picking. He considered mildew the greatest enemy to the Rose, and when he perceived it he cut off the infected branch or shoot. Speaking on the form of Roses, Mr. Bott expressed it as his opinion that Marie Baumann is the best form.

An interesting discussion followed on Rose growing, in which Messrs. T. Garnett, G. Gill, J. Hardwick, J. G. Brown, G. Parkin, and others took part. Mr. T. Senior, Solicitor, proposed a vote of thanks to Mr. Bott for his paper, which had, he said, been one of intense interest. Mr. Senior suggested that some of the Roses exhibited should be sent to the Clayton Hospital. Mr. H. S. Goodyear, in seconding the motion, endorsed the suggestion. Mr. J. Thomas, of Wrenthorpe, supported the motion, which was heartily carried and acknowledged.

A basket of Roses was made up for each hospital by Councillor Lupton, the curator, and the rest were distributed amongst the members. On the motion of Mr. H. Oxley, seconded by Mr. B. Whiteley (two of the Vice-Presidents), a very hearty vote of thanks was given to the exhibitor of the Roses, and the motion was acknowledged by Councillor Lupton.

ERRATUM.—In the report of the Wirral Rose Show on page 73, the first prize in Class 8 for twenty-four blooms, was doubtfully credited to Mr. Hall, whereas Rev. H. A. Berners was the winner of it.

REVIEW OF BOOK.

Notes on the Cultivation of Dutch and Cape Bulbs, Tubers, Roots, and Plants. By ANT. ROOZEN & SON, Overveen, near Haarlem, Holland.

THE authors of this little work have endeavoured to convey brief instructions on the cultivation of bulbous, tuberous, and similar plants generally grown indoors or out. The genera are arranged alphabetically, and perhaps the chief defect is that the instructions are too brief in several instances, but many useful hints are comprised in the 112 pages. Several hardy plants that are neither bulbous nor tuberous are included, the descriptions commencing with *Abobra* and terminating with *Zingiber*. A chapter is also devoted to "The Destruction of Insects," and a list of about 600 popular names of plants with their botanical equivalents is also given that will be useful to some readers. Many of the popular titles are, however, very far-fetched or mis-spelled, such as "Noah's Ark" for *Cypripedium pubescens*, "Parlour Palm" for *Aspidistra lurida*, "Pencock Tulip" for *Calochortus venustus*, "Thong Lily" for *Imantophyllum*, "Triplet Lily" for *Triteleia*, "Two Dollar Lily" for *Lilium carniolicum*, &c.

As examples of the style we quote the following:—

"*Freesia*.—Cape bulbs, producing flowers of the most delicious perfume when grown in the frame or cool greenhouse. Should be planted as early in autumn as bulbs are procurable, in a light rich soil, or a compost of loam, leaf mould, peat and grit or sand added for sufficient drainage. When planted in pots liquid manure should be applied once a week. Flowers in June and July, but may be forced into bloom at the end of December if required for Christmas decoration. They like bottom heat.

"*Fritillaria imperialis* (Crown Imperials).—Are exceedingly handsome, pendant, bell-shaped flowers of very tall form, hardy with protection, and they bloom early in spring if planted in good sandy garden soil about 3 inches deep. Left undisturbed for a number of years they form gigantic and picturesque groups among evergreen plants, &c. The beautiful varieties of red and yellow single-flowered *Fritillaria imperialis* are very bold and handsome when placed in the conservatory in company with dwarf-growing subjects. They bloom naturally very early in the season, and by potting the bulbs early, and assisting them with a genial temperature as soon as the young growth begins to make its appearance above the surface they are sure to do well. Single bulbs in 6-inch pots appears to be the best way of growing them. The striped-leaved varieties are worth growing for the sake of their foliage, but when surmounted by their coronets of bloom they are very beautiful. Sound loam, mixed with a small proportion of leaf mould, is all that is required in the preparation of the compost. In no case fresh manure or cow dung should be added to the compost.

"*Lilium* (Lily).—To this gorgeous, beautiful, and easily cultivated class of plants we have paid particular attention, and would invite special notice to our very complete and select collection. No class of plants capable of being cultivated out of doors possesses so many charms; rich and varied in colour, stately and handsome in habit, profuse in variety and of delicious fragrance, they stand prominently out from all other hardy plants, and no herbaceous border, however select, should be without a few of its best sorts. With a well-selected collection *Liliums* may be had in bloom from June to October.

"They should be planted from October till March, in a good rich loamy soil, abundantly mixed with decayed cow manure, but a deep soil is always of great importance. Plant about 4 inches deep. During winter it is advisable to cover the surface of the bed with a thin layer of manure, which will not only afford a slight protection to the bulbs, but will materially enrich the soil. However, care should be taken that no water stands round the roots during winter time, as this causes the bulbs to rot. In spring the manure may either be removed or dug in between the rows. The best time to transplant *Liliums* is in the autumn, but they also do very well when removed in winter and early spring. In any case care should be taken not to damage the roots and sprouts; mind also that the bulb does not dry. They may be left undisturbed for years, providing some manure be added every spring to the bed in which they are planted.

"All make excellent pot flowers with the exception of *pyrenaicum* and *pomponicum*. Being mostly of tall growth they are excellent for their stately and magnificent appearance when grouped with other plants, whilst the beauty of their outline and charming individuality lend an air of dignified gracefulness and 'sustained splendour' alike to the grandest conservatory and the tiniest greenhouse. Nearly all of them are deliciously fragrant, and the cut flowers are most excellent for the table, bouquet vases and glasses, the flowers being very lasting and opening full to the last bud in water.

"For pot culture, use an equal part of loam, peat, sand, leaf mould, and rotten manure, but the rougher the soil the better. Use deep pots,

as roots run very deep, and after planting plunge these in a bed of coal ash, manure, cocoa fibre, or ordinary open border, protecting them from frost, and bring them indoors or in the greenhouse at their time of flowering.

"*Ranunculus* (Crow-foot).—Hardy tuberous-rooted plants; when grown in beds and edged with dwarf flowering plants the effect is superb. As cut flowers they are quite as useful as the Rose itself, while for bedding, ribboning, massing and edging, in separate or distinct colours, the effect is truly magnificent in the spring flower garden.

"The culture recommended for them is to plant in the first quarter of the year, if possible in a moist and fertile ground, about 2 inches deep and 3 to 4 inches apart. *Turban Ranunculus* may be planted any time from November to March.

"Both *Ranunculus* and *Anemone* tubers are injured by damp, and must be taken up when fully ripened and kept quite dry till again needed for planting.

"If planted early in spring or at the end of winter, the beds should be protected with leaves or other covering in order to exclude the frost and sharp winds. A supply of liquid manure when plants appear will assist them very much in propagating, and will prevent the soil from becoming too dry. Should there be a season of drought a supply of water will be necessary. *Turban Ranunculus* flower in May, Persian and French varieties about three weeks later."

NATIONAL CONFERENCE ON APPLES AND PEARS.—A meeting of the Committee appointed to carry out this project under the auspices of the Royal Horticultural Society, met on Tuesday last in the Council Room at Chiswick, Col. Beddome in the chair. A form setting forth the object in view, and a schedule for the guidance of exhibitors, were considered. These, with forms for eliciting information, will be printed and distributed as soon as possible. The exhibition of fruit, which will consist of selections embracing a stipulated number of varieties, will be more than ordinarily interesting and instructive. Papers will be read, to be followed by discussions thereon, during the Conference, which will open on Tuesday, October 16th, and close on Saturday in the same week.

— **ROYAL BOTANIC SOCIETY.**—At a meeting of the Society, held on Saturday, July 23th, Mr. J. P. Gassiot, Vice-President, in the chair, Mr. H. E. Hunt was elected a Fellow, and the names of several others read for ballot at the next meeting. Several fine bunches of the Zante Currant Grape grown in the gardens were shown. The Chairman announced that the anniversary meeting would take place on Friday, August 10th. Mr. Henry Smith exhibited a flower of the Christmas Rose he had just gathered at Weybridge.

— **A LARGE MELON.**—Mr. W. Iggulden, Marston Gardens, Frome, has just cut a fruit of a new Melon raised by Mr. A. Miller, Rood Ashton, Trowbridge, which weighed 11 lbs. 3 ozs. A second fruit yet hanging on the plant will probably weigh 8 lbs, and both are handsomely netted. The variety is the result of a cross between the Hybrid Cashmere and Melndoe's Premier. It has a white flesh, and the quality is first-rate. For culture in pots and boxes it is one of the best, the fruit in this case not being too large.

— **GARDENING APPOINTMENTS.**—Mr. Page, late gardener at Fern Lodge, Bracknell, has been appointed gardener to H. P. Leschallas, Esq., The Highams, Bagshot, Surrey. Mr. Page is a very successful Chrysanthemum grower and holder of the Ascot challenge cup, and we wish him success in his new charge. Mr. W. Wilson, for some years foreman at Dropmore, Maidenhead, has been appointed gardener to W. Barron Esq., Sefton Park, Slough.

— "W. T." writes—"Your entomologist, "J. R. S. C.," stated some years since that the natural history of the CUCKOO SPIT FROG HOPPER INSECTS was obscure. Is that still the case? I see nothing of the hopper after August, and never see what lays the eggs upon the plants in May or June. I have never seen them so numerous and destructive as they have been this year. I have killed many thousands of them. While out the other day I discovered to my delight a fly killing a daddy long-legs. Is a fly known to be an enemy to the daddy long-legs?

and if so, might they not be encouraged? The hopper also in its egg-laying state might by some means be destroyed in its early stages."

— **THE GARDENERS' ORPHAN FUND.**—A largely attended meeting of the Committee of this Fund was held on Friday evening last. Mr. G. Deal was unanimously re-elected chairman for the ensuing year. The expenses in connection with the late dinner were examined, and found to have been met with a balance in favour of the Fund, and the bills were ordered to be paid. Votes of thanks to Sir Julian Goldsmid, Bart, M.P., the donors of plants and fruits, the local secretaries, and the hotel managers for contributing to the success of the event, were ordered to be recorded in the minutes. The Committee had then brought before them the generous offer of Mr. Sherwood to place a child on the Fund at his own expense, and for carrying out the benevolent project it was stated he would give a contribution of £100, the recipient of the benefit to be chosen by the Committee. This noble offer was thankfully accepted, and a child at once nominated—one of a family of ten children left fatherless and only two of them able to earn anything. It was then determined that the payments, commencing from July 31st, would be made to the guardians of the eleven elected candidates as soon as the contracts were signed, Messrs. Deal and Barron being deputed to conduct the transactions. An additional £500 were ordered to be invested in Consols, and the rules, with the report and financial statement, ordered to be printed for circulation among the subscribers.

— **AMONGST** the non-competing exhibits at the National Carnation and Picotee Society's London Show recently, was the new **CARNATION COMTE DE CHAMBORD**, that is likely to prove acceptable for cutting purposes. It was exhibited by Mr. Walker of Thame, and has pure white large and well formed blooms with a full Clove fragrance.

— **MR. T. S. WARE**, Hale Farm Nursery, Tottenham, sends us flowers of **HELIANTHUS RIGIDUS**, which is said to differ from the ordinary form in flowering fully three weeks earlier. It has now been in flower for several weeks, and though slightly damaged by the frequent rains affords abundance of its bright clear yellow blooms.

— **A NEW** weekly horticultural periodical, bearing the title of "The Garden and Forest," was commenced early this year in the United States, under the editorship of Professor C. S. Sargent. Each number contains twelve pages of matter the same size as this Journal, and the price is somewhat higher. It is well printed on stout paper, and freely illustrated with wood engravings and photogravures.

— **A CORRESPONDENT** states that at the distribution of prizes at the **CHILDREN'S FLOWER CLUB IN SPALDING** recently, Mr. G. F. Barrell delivered a practical and instructive address to the 400 competitors and the general company present. The principal gardening operations were admirably illustrated by apt comparisons and amusing homely language—exactly what was required on such an occasion."

— **UNDER** the title of "LIFE-LORE" a new monthly magazine has just been issued devoted to all branches of natural history, and it will no doubt find favour with numerous readers. It is well printed on good paper, liberally illustrated, and, judging by the first two numbers issued, will contain interesting articles upon a wide range of subjects. It is edited by Mr. W. Mawer, and published at 4, Essex Street, Strand.

— "**H. W.**" writes:—"Those of your readers who have visited Ilfracombe during the summer months will not have forgotten the grand effect which **CENTRANTHUS RUBER** produces on the Lantern Hill close to the quay of that charming seaside resort, and also in other parts of the town. The plant is a hardy perennial, 2 feet high, and produces a profusion of red flowers. It is also met with plentifully in the Isle of Wight, under the popular name of Isle of Wight Sedum. It is easily increased by division of the roots and by seed sown in a warm border in the month of August or spring."

— **TOOTING AND MERTON ABBEY HORTICULTURAL SOCIETY.**—On July 26th the monthly meeting of this Society was held at the rooms of the Conservative Club. The last meeting was held in June, that for July having been dispensed with on account of the busy horticultural season at which it would have been held. There were present Messrs. J. Eade (Chairman), Fullick, Jones, Lambert, Martin, Melhuish, Pugh, sen., Pugh, jun., Raven, Schneider, Seymour, Ware, Williams, and Whiteside. Mr. Seymour read an able and interesting paper on the Strawberry,

giving a detailed account of propagating, the class of soil requisite; and the varieties. Mr. Fullick exhibited some splendid specimens of "Dreadnought" Cucumbers, "Telephone" Peas, and Red and Black Currants, for which he received horticultural certificates. Votes of thanks to Mr. Seymour for his paper and the Chairman for his attendance closed the proceedings.

— **TRADE ANNOUNCEMENT.**—Mr. W. Denman, 7, Catherine Street, Covent Garden, London, W.C., Horticultural Agent, informs us that "Having for some years past recognised the importance of securing speedy transit and quick delivery in the case of all plants sent from the Continent to England, and *vice versa*; and having myself suffered great inconvenience, annoyance, and loss from causes which could easily have been avoided had the shippers entrusted with plants possessed any practical knowledge of their nature and requirements, I beg to inform you that my business with the Continent having become so extensive, I am now obliged to take up the business of a shipping and forwarding agent. I have secured admirable premises for this branch of my business at 12, Cooper's Row, Crutched Friars, London, with accommodation at the various wharves for the proper and prompt warehousing of the most tender plants. The business will be carried on under the style of Denman & Co."

— **THE** usual fortnightly meeting of the **WALKLEY (SHEFFIELD) AMATEUR FLORAL AND HORTICULTURAL SOCIETY** was held at the "Howard Hotel," Walkley, on Friday last, the President (Mr. T. B. Hague) in the chair. There was a large attendance of members, and the exhibits by members of plants and cut flowers were both numerous and of very high quality. Amongst them most noticeable were some exceptionally fine stands of cut Roses, and a collection of Delphiniums and Phloxes exhibited by the President; also a fine collection of Gloxinias (cut flowers), large specimen plant of *Adiantum cuneatum*, and other plants by Mr. F. Barnes; Tuberous Begonia and cut Roses by Mr. Herringshaw; a pretty collection of hardy Ferns (small healthy specimens) by Mr. C. Batty; and a remarkable collection of fine Mushrooms from Mr. Duncan Gilmour, jun. (Rose grower), grown on outdoor ridges, as advocated by Mr. Wright in "Mushrooms for the Million." A paper was read by Mr. W. K. Woodcock, entitled "Flowering Begonias; their History and Cultivation," which was attentively listened to and elicited much praise from the members present. A very interesting and useful discussion followed, and the usual votes of thanks concluded the business of what had been a very agreeable meeting.

— **A CORRESPONDENT** writes:—"Under most disadvantageous circumstances as to weather a pretty **VILLAGE FLOWER SHOW** was held in the cricket ground, Long Ditton, Surrey, on July 25th. The Exhibition was the first of the kind in the district, and the Committee may be congratulated on the success of their undertaking. Groups of plants arranged for effect were a pleasing feature, first honours being accorded to Mr. W. Palmer, gardener to W. F. Hume Dick, Esq., Thames Ditton House, for an arrangement which found many admirers. He was closely followed by Mr. Simmonds, gardener to G. B. Windeler, Esq., Long Ditton; the third prize being awarded to Mr. Farr, gardener to H. Speer, Esq., Thames Ditton. The latter exhibitor secured first prize for six good stove and greenhouse plants, comprising well flowered examples of *Plumbago capensis* and *Stephanotis floribunda*. Fruit was well shown by Messrs. Palmer, Simmonds, and Farr. Messrs. Sutton & Sons offered special prizes for their Perfection Tomato, the first prize being secured by Mr. W. Palmer, and the second by Mr. A. Farr. Amongst miscellaneous exhibits, not for competition, were handsome cut Roses contributed by Messrs. C. Lee & Son and Messrs. J. Veitch & Sons. The cottagers' vegetables and cut flowers were especially fine. Rather a novel feature was introduced in this section of the schedule, under the heading of "Industrial," prizes being offered for the best specimens of plain needlework in making, mending, and darnings. Her Royal Highness the Princess Frederica visited the Exhibition during the course of the afternoon.

— **MR. C. E. PARNELL**, writing in "Vick's Illustrated Magazine," respecting "THE BORDERED MORNING GLORY," says:—"Ipomœa (or, as it is termed by some, Pharbitis) limbata elegantissima, is a very beautiful rapid-growing annual climbing plant. It is of vigorous growth, attaining a height of from 15 to 20 feet, having cordate three-lobed leaves, at the axils of which are produced its very showy flowers. This variety is one of the finest of the genus, the large

funnel-shaped corolla having a rich, bluish-purple centre in the form of a star, and it is also bordered with a broad pure white margin. The flowers are produced in the greatest profusion from June until frost. This *Ipomoea* is a plant easily cultivated, doing best in a moderately enriched deep soil and a sunny situation. It does best when started under glass, and the seed should be sown about the 1st of April in a well drained pot or pan filled with rich loamy soil. Sow thinly and cover slightly, place in any warm moist situation close to the glass, and as soon as the young plants are strong enough to handle carefully repot them into 3-inch pots; pinch back the leading shoots frequently, and gradually expose to the open air, and plant out as soon as all danger of frost is over and the weather has become warm and settled. Support must be given before the plants commence running, and during the growing season they should be frequently examined, and the young shoots trained so as to occupy the required space, whether to cover latticework, trellis, or pillars. In dry weather the plants are sometimes attacked by the red spider, and as soon as this pest is noticed they should be freely and frequently syringed. Seeds are very freely produced, and by this means the plant is increased."

— CASSELL'S "Familiar Trees" for August deals with THE BOX, and in the course of the chapter the following remarks occur—"Reckless destruction of both the commoner and the more valuable kinds of timber trees has been, and is, only too frequent in all parts of the world. In not a few cases its effects are already being experienced in an insufficient supply of wood either for general use or for some special purposes. The rapidly increasing demand for the wood of the Box, especially for engraving, and the carelessness in the past as to the Caucasian forests of this timber, have now for some years excited apprehensions among the consumers and stimulated inquiry as to suitable substitutes for this material. The wood is remarkably heavy, being the only European timber that will sink in water; it is yellow, very hard, compact, and even grained, so as to be susceptible of a fine polish. It is still employed both here and on the Continent, for a variety of purposes besides wood-engraving, for which art, however, the finest quality of Boxwood is mainly reserved. It is used for inlaying, for mathematical instruments, especially foot-rules, for weaving-shuttles, and other turned articles. Some of these, however, are made at St. Claude, not from the stem, but from the root, the wood of which is often beautifully veined. The art of wood-engraving is older than that of printing, the old block-books, such as the "Biblia Pauperum" of the first half of the fifteenth century, being engraved on a series of large blocks. It is, however, only since the time of Bewick that wood-engraving has become general as a means of book illustration; as possibly the introduction of the many photographic and electrotypic processes now in vogue may afford a solution of the difficulty as to the supply of Boxwood in the future. Some Boxwood can, undoubtedly, be procured from India and the Cape; and of the various substitutes suggested, whilst our own Hawthorn seems the best, Pear, the American Dogwood (*Cornus florida*), the Texas Ebony (*Diospyros texana*), and the West Indian Trumpet-flower (*Tecoma pentaphylla*) all promise to prove useful."

— MR. E. L. LAYARD, British Consulate, writing to *Nature* on THE DISPERSION OF SEEDS AND PLANTS, has the following interesting remarks respecting Mr. Morris's article on this subject, which has been previously noticed:—"Thousands of acres of pasturage have been destroyed in this island by the distribution by birds of the Lantana, which was unfortunately introduced here by the first Roman Catholic missionaries to form a hedge for their property at St. Louis or Conception. The Gendarme plant (an *Asclepiad*) was brought here in a pillow by a Gendarme from Tahiti. It was a seed attached to a wing of silk cotton. The gendarme shook out his pillow; the wind carried the seed to a suitable spot, and now it vies with the Lantana in destroying our pastures. I have shot the great fruit pigeons of Fiji and this island with several seeds of the *Canarium* (?) in their crops, as Mr. Morris says, as big as hen's eggs. The seeds of water-plants are conveyed, with the eggs of fresh-water Mollusca, to vast distances, adhering to the hairs and feathers of the legs of water birds—ducks, herons, and waders of all sorts. In London the basins of the fountains in Trafalgar Square were peopled by *Lymnea* brought thither from the Serpentine, attached to the feathers of the sparrows who bathed, first in one, and then in the other. Another plant which occurs to me as being largely indebted to man for its distribution, is that known as the Cape Gooseberry, which is a native of South America. The Kaffirs call it the 'white man's

plant,' and say it follows the white man everywhere. I know it is found in India, Ceylon, Africa, Fiji, New Caledonia, New Hebrides. I really believe boiling it into jam does not destroy the vitality of the seeds. We have a plant here, bearing a lovely flower, but whence it comes no one knows. It has hard wooden seed capsules, each furnished with two hooks as hard as steel and as sharp as needles. These, hooking into the hide of any animal, would be carried for days until forcibly dislodged. The Bathurst burr (*Xanthium spinosum*) was introduced into the Cape in a cargo of wool wrecked at Cape Lagulhas, and spread out to dry, first there and then at Simon's Town, at both of which places the 'burr' sprang up. I believe and hope I destroyed the first and last plant of it that sprang up in New Zealand some twenty-five years ago. The seed had been brought in the living fleece of a fine merino ram. The owner was cherishing the 'wonderful new plant,' and was not a little horrified when I took out my knife and cut it down. He was more horrified when I told him what it was."

WEIGHTS OF STRAWBERRIES.

IN reply to your correspondent "Saxoring" I give below the weights of ten different varieties of Strawberries taken this season.

Name.	No. of berries in $\frac{1}{4}$ lb.	Average weight per berry.	Heaviest individual berry.
		Ounces.	Ounces.
1, Black Prince	19	0.21	0.33
2, Wizard of the North	12	0.33	0.50
3, Elton Pine	9	0.44	0.66
4, Vicomtesse de Thury	7	0.57	1.00
5, Filbert Pine	6	0.66	0.90
6, Sir Harry	5	0.80	1.00
7, British Queen	5	0.80	1.25
8, Sir Joseph Paxton	5	0.80	1.33
9, President	4	1.00	1.25
10, James Veitch	3	1.22	1.75

The above are fair average samples, chiefly grown on one and two-year-old plants. The Vicomtesse Hericart de Thury were especially fine, being grown on maidens planted out last August. Sir Joseph Paxton were much inferior to previous years. Of others, Keens' Seedling may be classed with No. 4, Dr. Hogg with No. 7, and Marguerite with No. 9. I never saw a Strawberry that weighed 4 ozs., but have often seen them turn the scale at 2 ozs. Even then the berries must be 2 inches through the thickest part at least, as a cubic inch of solid fruit only weighs about half an ounce. It would be interesting to learn the weights of the new varieties. King of the Earlies with us ranges with No. 3 on the above list. Noble, I suppose, will be equal to James Veitch. The above list does not pretend to be complete, and the record of a number of years would possibly alter the figures. They are, however, approximate, and may serve the purposes of your correspondent.—JOHN LOVELL, *Driffild*.

CULTURE OF EPACRISES.

EPACRISES, which may be considered as the Heaths of Australia, are much more accommodating than Ericas, the true Heaths of South Africa, as they will pass uninjured in an atmosphere that would not disagree with a general collection, when the Heath proper would be ruined for want of a current of fresh air, and, in consequence, become a prey to mildew with all its attendant evils. Both in their native countries are found to thrive best in open, exposed situations. Both are exposed to heavy rains at times; but also to long periods of bright sunshine and very warm weather. The one excites rapidity of growth, the other ripens and consolidates the wood. Such modes may be followed in this country by the experienced in the case of both families; but the inexperienced would find that in a close, warm atmosphere the Heath would become lanky and encrusted with mildew, whilst the Epacris would maintain its health and vigour. In other words, the latter will stand uninjured more extremes of heat and cold, of dry and moist air, and dryness and moisture at the roots, than the Erica.

One advantage of the whole Epacris group is, that whether what is called species, or beautiful garden florist-raised varieties, the most of them bloom in the spring, and if treated for the purpose might just as easily be made to bloom in winter. Many of them without anything like extra attention will begin to open their blooms after Christmas if the average night temperature is seldom below 45°.

We will first direct our attention to pruning, and describe two

different modes of treatment according to the circumstances and tastes of two different classes of amateurs. The first having reference to those who have a forcing-bed, or pit, or plant-stove, or a forcing-house—say a vinery or a peach-house at work, or can make one end of their greenhouse closer and warmer for a time than the rest of it; and the second, applying more to those who have merely a miniature greenhouse, the temperature and atmospheric condition of which can hardly be otherwise than uniform all over, and perhaps a small turf pit to assist in keeping that greenhouse gay and in good order. Taste may also somewhat determine the matter; as in the first case it will be possible to have long shoots from 12 inches to 30 inches in length covered with bloom from end to end, and in the others to have dense bushes covered with bloom, but chiefly from shoots a few inches long. Our mode of pruning them will constitute the basis for our general management.

Now, as to the first supposed conditions. We will conclude that the plants have finished blooming, and are in 4 or 6-inch pots, as they were obtained in autumn or spring from the nursery. Each plant therefore would have most likely a number of shoots; and the quickest and best way to get rid of all the decayed blossoms and incipient seed-vessels is to prune back all these shoots within 2 or 3 inches of their base. To make something of a symmetrical plant on this system the centre shoot or shoots might be left 9 inches long or more, another ring half as long, and the next cut in to an inch or so. This plan will give the plant something of a pyramidal appearance afterwards; and when once thus established each set of shoots may be cut back every year when done blooming, much as you would cut a Willow stool, leaving only a bud or two to each shoot. When plants are very young and in small pots it is as well not to cut back too close; and when the plants get old it is also injudicious to cut back into older wood than that made the previous summer. On this plan, therefore, either a Willow stool or a Vine on the spur-pruning system will furnish examples as to pruning the *Epacris*; only keeping in mind that it is on the wood springing from such spurs, longer or shorter, and well ripened before winter, that the bloom-buds are to appear and open the following spring.

When the plants are thus pruned the plants like a little rest. Allow them therefore to remain in an airy, shady part of the greenhouse for a week or so, and give but little water, as the evaporating surface will be mostly removed. A slight dewing from a syringe frequently over the top of the plant will be more serviceable than deluging at the roots. Hardy as the plants are, I have known them depart in dudgeon when under such circumstances the soil was waterlogged from too heavy and often repeated applications from the water-can.

The next thing, if possible, is to remove the plants to a forcing-pit or house—say to a temperature of 60° to 65° in May and June, or earlier if wanted early, and to give them a rather close, moist atmosphere. After this the soil must not get dry, but neither must it be saturated. The gentle sprinklings of the top frequently from the syringe will cause the young shoots to push vigorously from what was left of last season's growth; and if these are more numerous than can find room for growing, it is advisable to thin them a little when from 1 to 2 inches in length. When a little more than the last length is the best time for potting, if the plants require it. At any rate the drainage should be examined and fresh surfacings be given to the pot. At first we would recommend rather small shiftings—that is to say, after the fibres on the outside of the ball have been gently disentangled, and a little of the lower drainage removed, from half an inch to an inch space all round will be quite sufficient. We are now saying nothing about the large-shift system, as on the whole that requires extra attention, especially in watering.

The soil required should be mostly good heath soil, rather rough for the size of the shift, with a portion of silver sand and some little pieces of charcoal and broken pots to keep the soil a little open and allow the water free access to the drainage, which must be extra well attended to. I have supposed that no plant is repotted in which care has not been taken previously to see that the ball was moist to the very centre; as otherwise, in repeated waterings the moisture would be apt to escape by the sides of the pot, and leave the mass of roots in the centre as dry as a well-burnt brick—one fruitful cause of consigning many a plant to the rubbish-heap that otherwise might have flourished for years. When the plants are large and old a little fibry loam added helps to keep them strong and robust.

When this repotting is done the plants should be replaced in the same genial growing atmosphere, waterings given whenever the plants require it, and frequent dewings overhead administered from the syringe, and a powerful sun deadened until the shoots are progressing freely in length. Then the plants should still have the stimulants to growth referred to; but at the same time be placed in more open spaces, so as to enjoy the beams of the sun unshaded. According to the time when the plants received this treatment, by July or August, the plants may be removed to a cold pit, on which the glass may be kept at first for a week or ten days, just giving the plants enough air to prevent them getting overheated and drawn; and then just take off the lights for some hours in the morning and evening; and then remove them altogether in a week or so, except when there is a likelihood of heavy rains. At this stage the plants will stand and delight in the brightest sun; but the roots will be apt to be injured if the pots were fully exposed. But for this the plants in August and September would be as well in an open place out of doors as a cold pit. The latter helps to shelter the pots.

It will be seen that by the above method the object is to obtain long shoots, stimulated at first into growth, and then exposed to the sun to consolidate and ripen the growth, in order that the long shoots may be clustered from end to end with flower-buds. The plants should be housed

by the middle of October. When growing freely, a little weak, cool liquid manure will be of advantage; at other times I prefer it to be clear, pure, and soft. After housing, the plants may range in temperature, and with plenty of fresh air, from 35° to 40°. When kept a little higher the flower-buds will swell quickly. Some ladies are very fond of such long shoots, all bloom, for making bows and wreaths. Where the conveniences exist, this is, on the whole, the easiest plan for growing these plants well, and the method is so simple as not to confuse by intricacy. Its success depends greatly on being able to assist growth after pruning with something like a tropical climate. I have managed that in hot summers, with a common glass frame, by giving little air, shade when necessary, and a moist atmosphere until we considered it was time to harden the shoots. In such cases the sun acts as the heating medium in a hothouse.

The main features in the second mode are similar, but attended with less trouble as to giving the plants suitable positions during the season. In this case it is best to give the plants a bush form. Instead, therefore, of cutting back the young shoots that you received on the plant you had from the nursery, when done flowering it is best merely to nip off part of their points, and then tie out these shoots—some merely on a level with the rim of the pot, and others in intermediate positions between that and the central perpendicular one. After resting a few days, and syringing the stem and head, keep the plant in close and a little shaded. When the fresh shoots start the general management will be similar to the first case; only if you are not able, by shutting in the sun's heat, to make a cold frame or pit into a hothouse, with few exceptions the growth of your young shoots will be short, though there will be plenty of them. These, though short, will require ripening, as well as their longer rivals, and, therefore, by the end of July, or the beginning of August at farthest, the plants must either stand in an open sunny place in the greenhouse, or be placed out of doors in a turf-pit, or where the pots may be sheltered from the blaze of an autumn sun. If the plants are kept in the greenhouse, to prevent the pot getting too hot for the fine hairlike fibre roots close to its sides, it is a good plan to put the pot inside a larger one, and stuff a little moss in the opening between them at the top. By this mode, when the plants are fully established, very little pruning will be required every year, farther than just nipping back the shoots a little, and getting rid of the old decayed flower buds. Thus treated, and weak liquid manure given when the plants were growing, and a few similar doses when they were blooming, we have seen stubby specimens kept in 6 and 8-inch pots for a number of years; care having been taken to drain well at the first to prevent the entrance of worms, and surface with fresh compost every year.

For window greenhouses I would prefer the last plan. In a common sitting-room, the temperature at the window averaging 50°, with a fair amount of fresh air, the plants will keep well in the spring months for a month or six weeks, or more. If the temperature is higher it will be difficult to keep the atmosphere pure and moist enough in proportion, and the blossom will be apt to fall prematurely, and the plant to become unsightly. Under such circumstances the plants will be kept over the winter better near the window of an unoccupied room where little or no fire heat is used, and where a little fresh air can be given when the outside temperature is not under 35°. In such a place the plants should rarely be lower than from 35° to 40°. By closing such a room at night, it would be rare, even in winter, that fire in the grate would be needed to keep out frost. When there is no convenience out of doors, and it is desirable that the windows of the sitting-room should be as gay as possible, a sort of plant-room of this kind is necessary as a nursery-reserve for supplying the others. An *Epacris* plant so kept in winter will have a very different appearance in March and April when compared with one that was kept all the winter in the sitting-room, and exposed to the alternating heat and cold, and dried atmosphere, which are imagined necessary for the comfort of the family.

The *Epacris* has rarely succeeded as a window plant because some of these little matters have been forgotten. The following is something like the system to be followed:—Prune and grow as in the second mode, and the window of the living-room will then be none too hot. Place the plant outside the window by July and August, if possible, and place the pot inside a larger one, or place the plant in similar conditions out of doors. House the plant in October. Place it in the window of a room where little or no fire is used in winter; keeping the plant from frost by moving it to the centre of the room, and covering it if necessary, or lighting a small fire if absolutely essential. By March bring the plant to the window of the sitting-room, and with the extra heat and a little sponging, or rather brash-daubing with water, the buds will soon swell and open. When the flowering is over repeat the process. In winter, whilst kept cool and airy, the plants will want a little water, and that should be a few degrees warmer than the average heat of the room. With such care the same plants may ornament a sitting-room for years; without it they will rarely last above a season.—S. H. R.

MAKART DECORATIONS.

AN extremely elegant form of decoration, under the above name, has been brought into prominent notice of recent years, more especially by Messrs. Hooper & Co. of Covent Garden, who have given considerable attention to the matter, with very satisfactory results. The principal characteristic of the method is that dried Palm leaves, Grasses, and flowers are chiefly employed with most tasteful and durable results. It

is said that the artist Hans Makart had once decorated his salon with Palm leaves, Pampas, and Grasses in a very effective manner, when it was visited by the Emperor of Austria, and the style so much admired and praised that it at once became fashionable. Unquestionably some charming combinations have been produced, and one very graceful example of the Makart style is shown in fig. 11, kindly lent by Messrs.

peacock feathers, besides everlasting flowers, especially Rhodanthes, Cape Silver Leaves (*Leucadendron*) Immortelles, and many others.

RHODODENDRON CULTURE.

It is not surprising that a plant possessing so many good qualities as the Rhododendron should become a general favourite. Almost ex-

FIG. 11.—A MAKART REGAL BOUQUET.

Hooper & Co. as a typical illustration. It gives a good idea of what can be accomplished by artistic taste. Similar designs are employed for hanging baskets, as "wall bouquets," corner stands, wall pockets, fire-stove screens, mantel shelves, and side boards, all alike being distinguished by their lightness and variety. Several different species of Phoenix, Latania, Areca, Geonoma, and Cycas are employed with Bul-rushes, Pampas plumes, a great variety of Grasses, Eulalias, and a few

ceeding many of our native plants in hardiness, all that can desired in habit, and affording as great a diversity of colour as any flower, it deserves more attention than it usually receives, and certainly more than many plants that are eagerly sought after. Perhaps one reason of its being less extensively cultivated than it ought to be, is the idea that only a certain description of soil suits it. This popular idea is certainly carried farther than is proper, and I will endeavour to show that the plant, or at least the common varieties of it, can be grown in more kinds of soil than usually supposed, so that there are probably many

places where it might be planted with advantage, if right means were taken at first to insure success. Unfortunately, this is not always done, and the consequence is a failure, when it might have been avoided, and the cultivation of the plant is abandoned. Perhaps a little consideration of the conditions under which the plant was growing prior to its being tried on such a spot, may tend to explain the reason of failure, and point out a course more likely to be successful.

This plant seems to flourish best in the dry upland peaty soils which are met with in many districts; there its cultivation is desirable, and although for special purposes we often see large quantities of suitable soil removed to a considerable distance to make a bed, this cannot be done in all cases where the Rhododendron is to be grown. On the other hand, it must be admitted that there are many soils and situations where this plant will refuse to grow, but then these are much fewer than is generally supposed, and a due regard to some other points of the plant's culture will show that the number of intermediate sites or soils is very large, and that there are not many neighbourhoods which do not possess a suitable soil. Few plants more readily adapt themselves to removal than the Rhododendron, provided the operation be performed at the right time and in the right manner. The subject is so important, and the cases where failure occurs so numerous, that some remarks on these and the mode to obviate them seem desirable; I shall, therefore, under different heads make the remarks which may seem applicable.

SOIL.—Although much as has been written on this, I believe there are few who have planted the Rhododendron extensively on different soils who will not acknowledge they have been several times deceived in the results. Either the plants have not succeeded well when they were expected to do so, or they prospered where they were scarcely expected to grow at all; in fact, the soil requisite to support the healthy growth of this plant is far from being generally understood, and often a just knowledge of the matter is only attained by a trial. A number of plants are tried on some soil that appears to be suitable, and the result watched with interest; if successful, all is well, but if otherwise, the ingenuity of the planter is set to work to ascertain the cause, and a trial elsewhere is perhaps determined upon. I will now direct attention to the soils and situations in which this plant is found to thrive with more than ordinary luxuriance, and I will endeavour to point out how far they can be imitated elsewhere.

In taking a casual survey of certain districts it will often be found, that although a certain class of soil generally prevails, now and then patches of quite another kind are met with, entirely surrounded by soil of the prevailing character, and varying in size from less than an acre to the extent of several parishes, and it not unfrequently happens that suitable sites for the Rhododendron occur in such isolated plots. For instance, some places in the neighbourhood of Dorking are well adapted for the growth of the plant in consequence of the favourable soil cropping out, while the district generally is chalk, with a thin crust of overlying soil almost as white as the chalk itself; yet here and there patches of peat, or a close resemblance to it, meet the eye, while farther westward in the same county peat appears to form the staple soil of the district, extending from almost the centre of Surrey a considerable way into Hampshire, with occasional breaks and irregularities. This neighbourhood, so favourable to the growth of the Rhododendron, has been taken full advantage of, and some of the largest nurseries for the rearing of plants have been formed there.

Other districts also furnish similar sites. A peaty soil well adapted for the purpose exists in large breadths throughout many of the midland and western counties, Cornwall affording as many varieties of soil, with as large a proportion favourable to the growth of this plant, as any county. Speaking, too, without a thorough knowledge of the matter, I believe most of the eastern counties possess a much less extensive range of dry upland peat, although that of a marshy kind may be plentiful enough. Large tracts, however, exist in Derbyshire and Staffordshire, but the wet mosses of Lancashire have to endure a course of draining and cultivation before they become fitting abodes for this highly ornamental plant. Farther north peat is plentiful, and it is questionable whether any spot in the northern part of the kingdom can be found which is ten miles from a peaty moor, or some place of a like kind. Indeed, I am certain that there are not many places in any part of the kingdom half that distance from some spot where the Rhododendron will flourish, for a black peat is not the only soil that it will thrive upon, as it often exhibits every appearance of vigorous health on soils that to an ordinary observer look the very opposite of peat, and these, too, so different from each other that I am convinced the numerous places suitable for the growth of the plant have not yet had a fair trial. The black sandy peats of Surrey and elsewhere, with scarcely a stone in them as large as a boy's marble, bears no resemblance to some upland gravels, where stones varying in size from that of a cricket ball to a bean form at least three-fourths of the staple material the plants have to grow in, and yet fine healthy plants are met with blooming abundantly.

Colour of soil is no criterion, for a light grey, bright yellow, and now and then a dark red, as well as all intermediate colours, seem to answer almost as well as the black peat, while occasionally the latter is rejected. Most low-lying peaty morasses are unsuitable, especially those from which peat is dug for fuel. A period of cultivation may bring them into a suitable condition, but such peat is not so in its crude state; indeed, I hardly know what crops are most suitable for low, flat, peaty mosses, scarcely raised above the ordinary water level. I would caution the inexperienced against using this boggy peat in the formation of Rhododendron beds, as I have seen evil results more than once arise from its being employed. I cannot clearly say why it is so, but it

would appear that the long period during which the moss has been soaked with water has rendered it unfit, for a time at least, to support vegetation of any kind, except the few species which occupy it in its natural condition, and the Rhododendron is not one of them. I have seen several fruitless attempts to obtain a healthy growth of this plant in situations of the kind referred to.

A soil which of itself contains all that is wanted for the well being of the Rhododendron, is infinitely superior to any mixture of ingredients that the most skilful or scientific operator can make. Although many plants seem to relish the composts made for them, it is but seldom the Rhododendron does so, while very often the worst results follow. Therefore, when the natural soil of the place appears to be favourable to the growth of the Rhododendron, it is best to let it alone. Adding other materials is often injurious instead of beneficial.

When the natural soil presents the features which are favourable to Rhododendrons, try to grow these. The indications are weeds and other natural growths, and after much experience I have found no reason to depart from an opinion I gave many years ago, that one of the best tokens of a soil suitable to Rhododendrons is the common Foxglove, which if seen growing extensively in a wild state, I regard as denoting suitable soil, as much as the Heath, and certainly much more so than the common Brake Fern, although both the latter are generally associated with the Rhododendron when it is left to Nature. Some allowance must, of course, be made for the forms under which each is found; usually the Brake (*Pteris aquilina*), disappears in tilled ground, but this it not the case with the Foxglove, the latter flourishing in dry ground; while the wild Heath is often found in positions where there is scarcely the depth of soil necessary for Rhododendrons. Amongst trees the presence of Birch and Scotch Fir often indicates a suitable soil, that of the Beech the contrary. Furze is often found along with Heath, but it is not so safe a guide as the Foxglove. Perhaps, however, the Bilberry or Whortleberry may be taken as the criterion of a first-class Rhododendron soil; but this plant is not so widely disseminated as the preceding, and Rhododendrons will thrive well where this highland fruit is rarely met with, often in places far removed from it and similar moorland productions.

A gravelly soil sometimes suits Rhododendrons, sometimes a certain kind of sand is equally beneficial, while now and then ground composed almost entirely of stones, and these often large ones, seems equally serviceable in supplying the wants of the plant. At a short distance from where I write many hundreds of Rhododendrons are growing in a soil of the latter description; stones angular, as if recently broken, being mixed up with a yellowish soil by no means prepossessing in appearance, and the stones forming at least two-thirds of the whole. Many of them are three or four times the size of road metal, and a less likely place for success could not well be found, yet the plants flourish remarkably well in it; and during the hot weather we had last summer I did not perceive indications of any flagging or injury in any of the plants at that place, while at others full-grown plants in prepared beds succumbed to the heat and drought. The situation is elevated, being 400 feet or more above the sea level, and the stones found upon it are hard and well adapted to road-making, although widely different from flint and Kentish rag. It cannot be too well known that the character of the stones found upon land constitutes an important feature, and their too extensive removal has often been attended with bad results.

A very useful soil is often met with in a yellow sandy loam, not the hungry sandy soil which exists in some places, but sufficiently stiff to meet the requirements of many other plants, and which when laid down in grass is often covered with a multitude of wormcasts. Tracts of this character are found in many places, and in such there are healthy quick-set hedges. I am not aware of any soil much better than this for the Rhododendron. A large extent of soil of this description exists near the southern boundary of the county of Kent, and near Tunbridge Wells and other places. It also commonly occurs in Devonshire, and I recollect a friend near Plymouth pointing out to me in a park there the line of demarcation between it and a soil of an opposite character. On one side of this line the Rhododendron grew well, and the flowers of the Hydrangea were blue; on the other side the flowers of the latter were pink, and the Rhododendron dragged on a miserable existence. The soil alluded to does not make even a remote approach to peat, being bulk for bulk much heavier, and in no respect resembles it excepting in its capabilities of supplying the wants of the Rhododendron. Tracts of this kind of soil are met with even in close proximity to the chalk formation, for instance, near Dorking, but they are less common among great breadths of stiff clay.—R. J. B.

ROYAL HORTICULTURAL SOCIETY.

JULY 24TH.

SCIENTIFIC COMMITTEE.—Dr. H. Scott in the chair. Present: Messrs. Pascoe, W. G. Smith, G. F. Wilson, J. O'Brien, D. Morris, Dr. Hogg, and Dr. Masters.

Heteroicium in Fungi.—Mr. Plowright, in acknowledging the letter of thanks addressed to him some time since by the Chairman, on behalf of the Committee, made the following remarks:—"It was my hope when I began my cultures that the general outcome would tend to a lessening of the number of the species of the Uredineæ. This, however, is not the case; on the contrary, I feel convinced that physiological investigation will show that these parasitic fungi are much more numerous than we at present imagine. To take one instance only—that of the Uromyces,

which occurs upon Beans. It is now generally thought that one species is common to most of the Leguminosae. I have made a number of cultures on this point, and find that when *U. fabae* from the common Bean haulms is placed on young plants of Bean, Pea, Vicia Cracca, *V. sativa*, *Lathyrus pratensis*, and *Ervum hirsutum*, *Aecidia* are only produced on the Bean and Pea; and further, that the *Uromyces* on *Ervum hirsutum* applied to the same host plants produced its *Aecidium* on *Ervum* only. In the same way the *Puccinia* which occurs upon the *Compositae* is, I find, not one species, as is generally supposed, but that *Uredospores* from *Centaurea nigra*, for instance, will not affect *Taraxacum officinale*, neither will the *Uredospores* of *T. officinale* infect *Apargia autumnalis* nor *Lapsana communis*. Before the true affinities of these species can be satisfactorily determined numerous and long-continued biological investigations will have to be made, for the hasty grouping together of the various forms, because they occur on allied host plants, is as liable to error as the opposite plan of making every form a species because it occurs on a different host plant."

Malformed Cyrtopodiums.—Dr. Masters exhibited drawings and made comments on several malformed *Cyrtopodiums* which had been referred to him at a previous meeting. The principal peculiarities in different flowers were the following:—Imperfect development of the lip; adhesion of the lateral petals to the sides of the column, and consequent displacement: disjunction of lateral sepals, and presence of two lips in one flower. The adventitious lip might be the result (a) of additional development, (b) of sub-divisions of the primary lip, (c) of the presence in the guise of a lip of one of the outer stamens (A2), which is usually suppressed. Another flower had three staminodes, one corresponding to A1, and two lateral ones as usual, the stigma being distinctly three-lobed. From Mr. Kimball came a drawing of *C. Lawrenceanum*, in which the parts of the flower were arranged in crossed pairs. The most peculiar flower was one of *C. barbatum* exhibited by Mr. O'Brien. In this the general form was triangular, the upper sepal was wanting, the two lateral ones were present; the two lateral petals were also present, but in the shape of broadly ovate segments, more like sepals in shape, but having the position of petals, as well as the little tufts of hairs on the margins, characteristic of the petals in this species. The column was erect with two lateral shields concealing the anthers, while the ordinary median staminode was absent. The style was erect, cylindric, scarcely lobed at the top, and the ovary entirely absent.

Passiflora leuensis. × —Dr. Masters showed drawings of this hybrid, as also of *P. hybrida floribunda*, to show how closely similar they were. *P. leuensis* × was known to be a hybrid out of *P. kermesina* by *cærulea*, and *P. hybrida floribunda* in all probability had the same origin.

Movements in the Shoots of Pines.—Dr. Masters showed diagrams representing the movements, not only of the leader shoot of *Abies bifida* (firma), but also of the lateral shoots; while the leader shoot gyrates in irregular ellipses, its point being alternately raised or depressed, the lateral shoots not only move from one point of the compass to another, and are elevated or depressed, but are rotated on their own axis, the leaves also being raised or depressed at various angles. These movements of shoots and leaves were very complex, and in all probability dependent on different causes.

Growth of Philadelphus.—Dr. Masters exhibited a drawing of a plant of *Philadelphus* raised from a cutting in a pot. On shifting the cutting into a larger-sized pot it was found that a dense leath of roots had proceeded from one single point only of the callused end—not from the entire circumference. One lateral shoot only was, in the first instance, produced from the side of the cutting, and this shoot was on the opposite side to that whence the tufts of roots issued. Not till this one shoot had grown to a large size, and produced three or four pairs of leaves with internodes of considerable length between them, was a second shoot produced. From the base of the original cutting, opposite to the first, a third and a fourth were also produced regularly, first on one side, then on the other side of the plant, and nowhere else.

Aracaria brasiliensis.—Professor Henriques, of Coimbra, sent a photograph showing two fine trees of this species growing in the open air in the Botanic Gardens of the University of that city.

The Plymouth Strawberry.—Dr. Masters showed ripe fruits of this curious monstrosity, grown from plants presented to him by Mr. G. F. Wilson. It is an Alpine Strawberry, in which all the parts of the flower are more or less represented by leaves. The plant was mentioned by old botanical writers, but afterwards disappeared, or was so completely overlooked that its very existence was assumed to be a myth. Of late years, however, the plant had reappeared in several gardens, and the correctness of the old writers has been vindicated.

Hybrid Clematis.—From Mr. Noble came specimens of his *C. Jackmanni alba*. The ordinary Jackman Clematis produces its purple flowers in late summer on the young wood of the year. The white variety, however, produces flowers in the spring, on the old wood of the preceding year, and which are more or less irregular in character, and again flowers on the herbaceous shoots later in the summer, thus showing in one and the same plant the characteristics of two distinct sections of the genus, and affording evidence of the hybrid origin of the plant in question.

Stag Beetle.—From Mr. Roupell came a specimen of *Lucanus Cervus*, stated to be very abundant this season in certain localities. While the perfect insect, in spite of its formidable appearance, is harmless to plants, its larva is very destructive to the wood of trees.

TRIALS AT CHISWICK.

A MEETING of the Fruit and Vegetable Committee was held at Chiswick on July 26th. Present—Harry J. Veitch, Esq., in the chair;

Messrs. Lec, Warren, Pearson, Ross, Rivers, Marshall, Norman, and Denning.

The collection of Peas growing in the garden was further examined. Dr. Hogg, from Messrs. J. Veitch & Sons, was noted as a very fine stock. Midsummer Green was condemned as worthless. Optimum (Laxton), a tall green Marrow, having large handsome pods resembling Telegraph, was approved. Prince of Wales was noted for its extraordinary cropping qualities. Pride of Kent (Divers) and Gloria Mundi (Yates) were considered to be *Ne Plus Ultra*. The *Abbot* (Hurst & Son), a wrinkled green Marrow resembling Telegraph in appearance, but of superior quality, was greatly approved, and received a first-class certificate. Reliable (Laxton) a dwarf green wrinkled Marrow of the Scimitar type, was approved for its free cropping qualities and well-filled pods. Empress (Eckford), a tall green wrinkled Marrow, was approved as a good cropper and of good quality. *Ne Plus Ultra* Seedling (Culverwell) was considered a good stock of the old variety.

A collection of autumn sown Onions was inspected, the various types and selections of White Spanish, autumn sown, were noted as superior to the Tripoli section this season. Bailey's selected White Spanish (Veitch) was highly commended by the Committee, being considered the best selection.

Tomatoes were inspected. Messrs. J. Veitch & Sons submitted examples of *Raspberry Superlative*, referred from the meeting at Westminster, together with examples of Lord Beaconsfield and Semper Fidelis for comparison. They were considered quite distinct. Superlative, being far superior, was awarded a first-class certificate.

Mr. T. F. Rivers submitted examples of a seedling Peach and Nectarine raised from the Nectarine Peach. The Nectarine was remarkable for its enormous size, being 10½ inches in circumference, and 10 ozs. in weight.

THE COMMERCIAL REALISATION OF FRUIT.

A CORRESPONDENT sends us a report of a paper on the above subject that was read by Mr. D. Tallerman at a meeting of fruit growers in Kent early in the summer, and asks for its insertion in the Journal. The subject is discussed from a mercantile rather than a cultural point of view, and as suggestive hints are furnished we comply to a large extent with the request alluded to.

FRUIT FARMING.

Taking this as a branch of agriculture for special consideration, upon looking at the actual results obtained (so far as can be ascertained) by home and foreign fruit farmers they exhibit a most alarming difference to the detriment of the former. The estimated results per acre are not so accurately obtainable for orchard produce as for Wheat, Potatoes, hay, &c., which are cultivated on a large scale, and the gross yield weighed, thus furnishing the data by which the actual result is known; but taking the estimate of experts on this side, and the actual known and published results that have been obtained in America and Canada, a fair basis is obtained for arriving at a conclusion. In an estimate of the value of our crops recently made by Mr. James Howard, whose ability to perform the task will be freely admitted, and whose published estimate remains unquestioned, it will be found that he places the value of orchard produce at £20 per acre, which on the 200,284 acres in cultivation throughout Great Britain makes a total value of the crop £4,005,680 sterling. Looking to the known revenues derived from fruit cultivation in America, it will be found to range from 200 to 300 dollars per acre, or from £40 to £60 per acre, while in Canada it was authoritatively stated at the last annual meeting of the Nova Scotia Fruit Growers' Association, in a paper read by Dr. Henry Chipman, that the known cash returns obtainable for the yield per acre were 300 dollars, or £60 for Apple crops, and 664 and 648 dollars per acre for Gooseberries and Currants, in 1886 and 1887, being £135 and £124 per acre respectively. In accordance with these results our home fruit farmers should have realised the additional sum of at least eight to ten million pounds sterling for produce of the 200,284 acres of land they had under cultivation. This it will be admitted is an enormous amount, and as that or any portion of it would have been extra profit, it is of a sufficiently serious character to command the most earnest attention of all engaged in that particular branch of agricultural industry. In considering the difference in results, the means by which they are secured naturally come under notice, and this brings attention to the commercial operations attending realisation, and when the closer these are scanned the more evident it is that they in a great measure arise from the varied course of procedure.

COMBINATION.

This is largely practised abroad, and invariably leads to good results, and it is capable of yielding more beneficial advantages to the fruit farmers than to any other of the branches of cultivation connected with agricultural industry, inasmuch as with care and tact it may tend to double, treble, and in some instances quadruple the amount receivable for portions of their crops, without in any way adding to the cost of production, and not materially affecting those of preparation. It is interesting to follow the course fruit farmers of other countries would pursue if they occupied Kentish lands for cultivation, and had to deal with and realise its products.

The Canadians would forthwith concentrate themselves and establish an association for their mutual advancement and other organisations in every district, the members of which would meet and exchange notes,

experiences, and opinions; they would hold their quarterly conventions of delegates from each and all of the district societies of their province, who would disseminate their views and conclusions, and do their utmost to spread all the most interesting information connected with their particular industry in the most practical and effective manner possible; and so far from being exclusive and isolated the greatest pleasure of those attending would be derived from the largest and most personal amount of information they could furnish, which, being duly recorded, printed, and published in their societies' transactions, is distributed far and wide in all directions for the benefit of their own members and other colonists. After supplying their local markets and making shipments of some of their Apples, the Canadians would, by means of a drying stove, or hot-air chamber, extract the moisture from the remainder of their crop, putting it into a condition by which it will readily keep, can be easily packed, economically transported, speedily sold, and greatly improved in value.

The Americans in Kent would follow much the same course, but would not be content to simply dry or evaporate their fruit crop, but would deal with it in a number of ways. They would dry some portions in the sun; other portions they would preserve in tins which they call canning, some of the fruits would be put up in their own juice for cooking purposes, and some in syrups for dessert use; portions would be made into a preserve, which they term "fruit butters," while considerable quantities would be sent into a cold store, so as not to overload the markets with green fruit during the middle of the season when everything is cheap. The markets in the locality and at a distance would be gradually supplied, and what is sent for sale would be carefully sorted into qualities and sizes, and packed into small boxes, baskets, or crates that are readily and safely transmissible by refrigerator cars or portable cool chambers from the fields of the south to the markets of the north, east, and west. The American at home recognises and advantageously puts into practice two golden commercial principles unknown to the farmers of this country. The first is, that the nearer their packages of produce are to the requirements of the consumers the less number of middlemen and handling is required in its distribution; the second is, that by properly and effectively classifying the contents of their packages, his produce is in a position to reach distant and unknown purchasers in every direction and at any distance, who can safely purchase by the known description; whereas if it is packed in a general and promiscuous manner—the same as is done by the English farmer—it must of necessity be sent to an adjacent market for disposal (where the sale is limited) to those that can attend it.

In this way the Americans exhibit a sound commercial knowledge by their practice; they command an unlimited number of buyers, and can supply bare markets where prices invariably rule high, while the English producer is confined to the one local market and those that attend it, which is invariably glutted, and prices rule low. Americans if in Kent would make short work of the railway difficulty from which Kentish farmers now suffer. Before a day was over they would promptly meet as a body, and grasping the position would deal with it in a straight-away fashion, and in less time than it would take an English farmer to get up a good grumble the Yankees would establish and be running a water communication by means of punts, barges, boats, and other vessels into all the accessible spots that could be reached by sea, river, or canal, where a basket of fruit or other goods could be got to be carried away; the contest, fixed and determined, would last until the railway authorities understood the position and made reasonable terms.

The Frenchman in Kent would act quite differently; he would make up as much fruit as he could into dainty little boxes or baskets packed as tastefully and carefully as if they were wax flowers, marvellously matched in size, colour, and character, so as to tempt their purchase, and by their luscious appearance give pleasure to the consumer, while large quantities would be preserved by being boiled in sugar and converted into crystallised dessert fruits of various kinds.

The Italians and Portuguese would preserve their surplus crop by converting them into fruit pulps, that they might be used at a later season for domestic or manufacturing purposes, that could be easily and cheaply transported and sold at any time.

While the Spaniards, Turks, Bosnians, Greeks, Cypriots, and Algerians would dry their crops the same as they now do their immense supplies of Plums, Figs, &c., that they at present cultivate in their respective countries. In fact, transplant fruit from any part of the world into Kent, and each and all would do something that would tend to give an extended market, and consequently a better value to the bountiful gifts with which Nature endows this delightfully charming county; while the general and unanimous impressions that would be felt would elicit expressions on all sides, and in all languages, at the careless and utterly wanton single course pursued by Kentish farmers in recklessly packing their choice soft fruits into the enormous sieves they now do, and sending them anywhere, anyhow, to be disposed of at any price, would not tend to raise Kentish farmers in their own estimation, did they hear and understand the remarks that their course of procedure give rise to.

Strange as it may appear at a first glance, it will nevertheless be found to be true, that the courses pursued by all fruit farmers abroad could in most instances be readily, profitably, and more advantageously carried on by fruit farmers at home, and more especially by Kentish farmers in their own county than by the foreigners in their respective countries, inasmuch as their districts are within easy reach of the great centres of consumption of the kingdom, and a few hours bring them into connection with nearly 40 millions of consumers, and with all those parts of the country where little or no fruit is grown, but where

large populations reside, and much fruit would be consumed, if it were readily available as an article of luxury or food in any of the numerous forms that have been mentioned.

Fruit-growing in the United Kingdom may be said to be a distinctive English industry, as while the total orchard area of England is 195,071 acres, that for Wales is 3,341 acres, and for Scotland 1,872, or 200,284 acres in all, the total area for market gardens being 60,850 acres, of which England possessed 36,650. It is curious to note that of the orchard area six English counties comprise two-thirds of the total—viz., Hereford 27,112 acres, Devon 26,414, Somerset 23,640, Worcester 18,527, Kent 18,296, and Gloucester 15,500, being 129,489 acres in all. This concentration of fruit cultivation should favourably lend itself towards the success of any movement towards the introduction of new means of collection, preparation, distribution, and realisation.

EVAPORATING FRUITS.

There is a known natural law in existence which teaches us that all animal and vegetable products may be preserved for an indefinite period by the extraction of their liquid constituents, that therefore results derivable by the use of an apparatus similar to the Blackman ventilator in connection with the kilns and oast houses that largely exist throughout the county of Kent may lead to bringing into active operation an economical and speedy means for the preservation of a large amount of human and animal food. The actual ultimate result from this operation it is not possible to foresee at present; but I am satisfied that, if the men of the country who think for themselves devote some consideration to the subject as to how this principle of desiccation can be practically utilised in the direction I have pointed out, beneficial results of a marked character will reward the country for their labours. Combination, refrigeration, and evaporation can be made to yield results to the fruit farmer little short of marvellous. By their means the length of the fruit season may be materially extended. The entire yield of all crops utilised, their commercial value greatly increased, and an unlimited supply of home-grown fruits made available as an addition to the food supply of the nation. The avoidance of these self-inflicted losses would do much to benefit the agricultural interests. Taking the various systems practised abroad that could be speedily brought into active operation in Kent, it will be found that they may be divided into separate classes as follows:—

1st, Primarily, the marketing of green fruits to ensure highest prices is essentially a matter of commercial experience. To this end all fruits should be properly sorted and classed as to character and condition into "Choice," for special high-class trade; "Prime," for first-class trade; and "Ordinary," for general trade.

2nd, Assorted as to description into firsts, seconds, and thirds sizes.

3rd, Choice and prime fruits should be packed into clean, bright, and carefully made packages, so as to present to the buyer a luscious, attractive, and tempting appearance. Ordinary fruit may be packed for general sale in smaller baskets than at present.

4th, It is important to act on the principle that the smaller the package the wider the area of consumption, and the better the contents will keep in good order and condition.

5th, Also that selection as to size and colour with regular packing are the best means for ensuring speedy sales in extended districts at good prices.

6th, Growers should remember and act on the fact that a barely perceptible taint or speck that is carelessly dealt with by the packer at the farm will in a short time become an odious blemish, and by the time the fruit reaches the market, not only becomes spoiled itself, but damages other fruit and spoils its value.

7th, A good crop requires marketing with commercial experience and judgment. A combination of growers to amalgamate their crops in order that large selections of particular descriptions may be made available for disposal in special directions, and in districts where required, will lead to large prices being received.

8th, Specially choice goods, suitably packed for display in retailers' shop windows, will at all times command extremely high prices.

9th, Inferior specimens of fruits packed with prime specimens reduce the value of the prime.

10th, Goods packed, branled, and numbered that their contents and condition may be known without a personal inspection, will be sent for by purchasers in remote parts, whose convenience or ability does not allow them to attend a market personally,

COLD STORAGE FOR FRUITS.

1, Green fruits may be safely stored in a cold, dry air chamber, and retained in a fresh condition for two, three, or four months at a temperature of 40 to 43 degrees Fahrenheit.

2, This temperature may be maintained in a perfectly insulated room of considerable extent by a moderate size machine.

3, The machines for refrigeration or the production of cold air vary in character, the principal systems being—

4, Mechanical, by the compression and expansion of air.

5, Chemical, by the conversion of ammonia—ether or sulphuric acids into gases.

6, Both systems are subjected to a great number of variations of detail, some of which are protected by patents.

7, The ammonia system is the one most generally employed, as it can be readily used for the production of ice when the cold air is not required for other purposes.

8, A cold air chamber is nothing more than an efficient larder.

9, To preserve by cold air it is but necessary to spread the fruit out on trays or shelves, and allow them to remain until required.

10, By this means of preservation a small quantity can be at all times withdrawn, and regular supplies sent to market or otherwise disposed of at good prices, for a long time after the termination of the ordinary fruit season and when the bulk of fruits are disposed of.

(To be continued.)

CHEALS' PATENT FLOWER SUPPORT.

MESSRS. J. CHEAL & SONS, Crawley, Sussex, have recently exhibited a simple method of supporting flowers in small vases or glasses, which will be found useful by some who have little time to give to work of this character. The supports are formed of wire, as shown in fig. 12, a series of small arms terminating in a ring springing at

FIG. 12.—FLOWER SUPPORT.

different levels from the same stem, either only on one side or radiating in all directions. When filled with single Dahlias, for which they are especially adapted, they appear as in fig. 13, but any other flowers can

FIG. 13.—FLOWER SUPPORT, FILLED.

be similarly employed, and some are made less formal than the Dahlias. The flower stalks are drawn through the rings and passed into the vessel of water at the base, using sufficient foliage to conceal the frame

and impart as much grace as possible. If not packed too closely and formally they have a rather pleasing effect.

SAVING THE LIVES OF FRUIT TREES.

IN March last I had from a nursery a tree of a new Apple. It had been budded the previous year, had a good root, and one straight shoot. The soil had been shaken from the roots, the whole was wrapped in straw, and sent per parcel post, being four or five days on the road. When it reached me the roots were quite dry, and the shoot which formed the top was shrivelled. I placed it in one of the basins of the fountains close by, where it remained four days. When I went to look for it it was swimming on the surface of the water, but a very different tree from the withered and three-parts dead specimen I had cast in on its arrival. The wood, roots, and buds had become quite fresh and plump, and all parts were in capital condition for planting. It was carefully planted at once, and at the present time it is a luxuriant little tree, with many side shoots. Had it not been for its prolonged ducking I feel sure it would never have come into leaf, and I am of opinion that Roses and other plants which are sometimes received in a shrivelled condition would be greatly benefited by being subjected to hydropathic treatment for a few days before being planted.—J. M.

ARTIFICIAL MANURES.

It was rather interesting to observe how in a recent contribution Mr. Dunkin proceeds to demolish and explain away all "erratic statements and impracticable theories," as he terms them, when they take the form of opposition to his ideas. How far he has been successful I will leave your readers to judge, as it will serve no useful purpose to prolong this debate now that I have obtained definite answers to the three principal points in this controversy. But as your correspondent desires a ray of light to disperse the darkness in reference to the mode in which we carry out some of what to him appear impracticable theories, I will endeavour to briefly explain our procedure. In the first place the scene of our operation when potting a miscellaneous collection of plants does not present the spectacle Mr. Dunkin's fervid imagination leads him to fancy. True we have various receptacles disposed around, containing alumina, humus, oxide of calcium, silica, carbon, phosphates, potash, and ammonia, from which we derive the materials for our compost heaps. Now if I was the rabid scientific enthusiast my adversary implies he should employ these terms when giving directions to form a potting material, but on the other hand the common terms, loam, leaf mould, sand, lime, charcoal, and artificial manure suffice, and then when a particular plant requires attention we proceed to compound for its need, and by having all the elements for a plant's support as far as its roots are concerned at hand and our mind well stored with knowledge, whether gained by scientific research or experience and observation—it matters little so long as it guides our hands in measuring out "a properly proportioned combination of the elements needed"—the work will be facilitated, and the results looked forward to with confidence. How Mr. Dunkin fancies that I do not take into consideration the various stages of a plant's growth I am at a loss to understand, for how does he think it possible to arrive at anything like an accurate knowledge of the elements needed unless this point has careful consideration? and in a previous article having this in view I mentioned the desirability of having the different chemical constituents of the plant food separately, so that they could be combined by the scientific cultivator in such proportions and at such times as his judgment tells him is necessary.

There is another point in Mr. Dunkin's correspondence to which I would wish to draw attention. It is where he repeatedly uses the words "minutely" and "nicely" instead of "properly" in reference to the system he so strenuously opposes. These adjectives are merely creations of my adversary, and have never been used by myself in any stage of the controversy, and in the way used are, I presume set up by your correspondent, so that he can have the satisfaction of levelling his sarcasm at such delicate operations in the practice of compounding plant food, which he considers should be performed in a more general method. Of course a properly proportioned combination would in a certain sense be a minutely and nicely proportioned one, but not in the way that your correspondent endeavours to construe the fact.

One place especially where I take exception to his remarks is when he says "Experience teaches us that for practical purposes no better results are obtained by the use of these minutely proportioned mixtures so long as the principal constituents of plant food are present." Now, if Mr. Dunkin seriously believes the truth of this statement, and intends to follow the "rough and ready" mode of cultivation given in this quotation, I should advise him to consign to the flames the works of Wagner, Parks, Ure, and other authorities he quotes from, if he does not wish his conviction on this point to undergo any change. All works on chemistry, whether practical or scientific, that I have as yet seen, point to minute precision as essential in the study and practice of chemical matters. In gardening, as in any other occupation, attention to trifles is undoubtedly the key note to success, though I must admit that results are sometimes achieved that apparently do not seem to favour this view

still, I affirm a larger per-centage of successes are attained through care bestowed on minute particulars than otherwise.

In reference to the lime question, as answered by Mr. Dunkin in the quotation he gives from a scientific authority—instead of a note based on his practical experience, as I expected, and which to be consistent he should have at least coupled with the scientific part—I have the temerity to criticise both from a practical and scientific point of view. The transfer of the subject of debate from old kitchen gardens to grass lands by your correspondent puts some slight complications on the case, but not material enough to hinder its discussion; but keeping to kitchen garden soils and their treatment, I will endeavour to show where in my estimation the dual use of lime is to a certain extent anomalous. Take, for example, a piece of ground that has perhaps for centuries been used for raising garden produce, and has of course been subjected to heavy dressings of farmyard manure; this causes a breakdown of “proper proportions” in the constitution of the soil, more humus being present than silica, consequently the soil presents a close inert mass of black matter, difficult alike for the passage of air, water, or heat, and consequently healthy root action. To correct this unhealthy state lime is a powerful agent, and judicious trenching another. Lime, in its chemical and also mechanical action, as set forth by Parks, I quite agree that the explanation why it is so admirably fitted for that purpose is a very lucid one, its action when first applied being purely chemical; afterwards, when its power in that direction is exhausted, it forms a valuable mechanical agent in contributing to the porosity of the soil. Now, taking the case of sandy soils, and the benefit likely to accrue from the application of lime, I must admit that my experience is so limited that I have not yet observed any sandy soils “that have received heavy dressings of farmyard manure for years, till by their very richness they become distasteful to many crops.” Again, take the effect of an application of lime on a thorough sandy soil: does the dressing produce as profitable results in causing the soil to be more retentive, as it does on heavy land in making them less retentive? I venture to say, emphatically, No! Because the scientific study of the action of lime reveals to us that it would have some slight effect in causing more moisture to be retained on its reversion into chalk, I do not consider it wise to put too much stress on its usefulness in that direction when there are other more powerful agents that will accomplish this object more effectually, such as humus, comprising all kinds of organic remains that naturally have power of retaining moisture, salt, nitrate of soda, sulphate of ammonia, and other chemical compounds that have an affinity for water. These in my opinion would be far preferable to lime on a sandy soil where the object was to promote its fertility.

As to my evasion of some of the arguments as mentioned by Mr. Dunkin, I think they are more imaginary than real; still, to satisfy his desire for an argument or explanation against his statement “that while certain elements are absorbed by the soil and only given up again in small quantities, while others remain freely moveable, and a residue not quickly taken up by the plant would be wasted,” I will supply him with one in an extract taken from a previous article of his, where he says, “I do not believe that any one kind of manure, whether artificial or otherwise, contains all the constituents necessary for supplying the right kind of food for plants generally,” and further on, in a direct question he says, “As to the possibility of producing a perfect plant food, I consider it may be accomplished in exceptional cases, but would be too expensive a system to become general for all classes of plants.” Now the explanation of absorption and loss lies between these two statements. If the food administered does not contain the right proportions, those elements in excess, if volatile, will be lost, and the plant have to go short of those not present. The question is then one of cost, as to whether it will be more expensive to try to manufacture a perfect plant food, or let the chance application suffice, and not trouble as to any residue that would be wasted. I think Mr. Dunkin will agree with me that the former course would be the best, and I was glad to see he has so far admitted the possibility of a perfect mode of applying plant food that would obviate this difficulty. As the settlement of the change of food theory rests on the question, I think I may be pardoned for pointing to a quotation from your correspondent, “J. M.,” page 274. He says, “Really good artificial manures, such as are advertised, contain the very essence of plant life,” and again, on page 384, another correspondent, “B.” says, “If we consider the matter I think it possible to procure a perfect plant food,” so that unless Mr. Dunkin obtains more independent support for his views, and does not produce more convincing arguments, I shall consider that he has failed to establish his case.

In conclusion, I beg to inform Mr. Dunkin that I have endeavoured to keep in mind throughout the foregoing his advice to me expressed in the motto, “Be just before you are generous,” and have, as far as possible, kept the justice of my expressions foremost, and if he should unfortunately fail to obtain the verdict, I will do my best to exercise the latter part of this excellent advice on his behalf.—M. COOMBE, *The Gardens, Ashton Court, Bristol.*

CORDON GOOSEBERRIES.

ON paying a visit last Thursday evening to Mr. E. Durrant, a well-known amateur in our village, I was surprised to see the splendid crop of Gooseberries he had growing on the cordon system. Never having seen this system carried out before with Gooseberries, I asked if they would count the fruit on one of the trees, when they found 264 Gooseberries on a tree 3 feet 6 inches high. I was

informed that the trees were from three to eight years of age, and had been pruned on the spur system, the shoots kept well pinched-in during the summer. They have never failed in having a good crop each year. I have forwarded nine fruits taken from the tree. The advantages I see to be gained in growing trees like this are that the fruit can easily be gathered, is kept cleaner, easily protected from the birds in spring, and afford an almost certain crop.—A. J. BROWN, *Lindfield, Sussex.*

[The fruits sent were very fine examples, and we have frequently seen similarly good results both with Gooseberries and Currants. One successful exhibitor in Perthshire grows all his best fruits in this way.]

STEAM AS A SUPPORTER OF COMBUSTION— WATER GAS.

THE enclosed clipping is from the *Yorkshire Post*, and contains an article on “The Manufacture of Water Gas,” which, to a certain extent, verifies the ideas I advanced on “Steam as a Supporter of Combustion” when discussing the advantages of water in ash-pits with Mr. Bardney and others. Perhaps you will be able to find space for its insertion in the Journal, as the facts therein contained will tend to convince those in doubt of the economy obtained by the aid of steam or water vapour passing through the furnace fire.—J. RIDDELL, *Duncombe Park.*

Under the direction of Mr. Samson Fox, C.E., the managing director, Mr. Lawrence Wildy, the engineer to the Leeds Forge Company, has recently erected at the company's works at Armley plant for the manufacture of gas from water, and at the present time the product is being used there for illuminating as well as for metallurgical purposes. In this country the making of water gas has not previously been undertaken on a commercial scale, but in many cities and towns on the Continent, railway stations, churches, hotels, works, and other buildings, as well as the public streets, are lighted by means of water gas, which is also used at one place for the purpose of driving the waterworks engine. There can be very little doubt that its successful installation and application at the Leeds Forge will lead to its extensive use in England. Water gas is produced by the decomposition of steam in passing through a mass of incandescent fuel, the resultant gas being hydrogen and carbonic oxide in about equal proportions. Ordinary coal gas contains about 50 per cent. of hydrogen, from 40 to 41 per cent. of marsh gas, and a small per-centage of other heavy hydro-carbon gases. Water gas, on the other hand, is made up of about 50 per cent. of hydrogen and carbonic oxide, and is entirely free from marsh gas and the heavy hydro-carbons. Water gas is consequently a non-illuminant in itself, but for lighting purposes it may be carbureted or used in conjunction with a Fahnejeim comb. This comb, which is fixed immediately over the gas-burner, is made of magnesia, with a small per-centage of bonding material, which is pressed when in a plastic state into the form of fine rods about the thickness of the lead of a pencil. It is claimed for water gas that it could be put to the same purposes as coal gas, and with greater advantage. First, as to its use in the foundry and the forge. The temperature of the water gas flame is something over 5000° Fah., and is 50 per cent. greater than that of the Siemens or producer gas usually employed for metallurgical purposes. Consequently for welding or melting purposes, and where a particular flame is required, water gas is the most suitable heating medium. It is pointed out that the chief reason why water gas produces so intense a flame is that the amount of air required to burn it is only one-half the quantity necessary for burning coal gas, while the area of the flame is not more than one-sixth that of the latter. In this way we get a greater concentration of heat, a less area of flame for radiation, and a very much smaller percentage of diluent nitrogen, which under any circumstances has to be heated up to the same temperature as the furnace or bath of metal.

The production of water gas, while, as before stated, not absolutely new, has never previously been carried out upon the same principle as that adopted at the Leeds Forge. Hitherto the water gas has been to a large extent diluted with generator gas and other products. At the Leeds Forge the water gas is collected separately and the producer gas is used for heating furnaces or boilers and in the annealing apparatus. In working the Siemens-Martin furnace the advantage of using water gas is said to be enormous. When the ordinary producer gas is employed the furnace will yield about twelve charges per week of six days. By mixing water gas with the generator gas the charges may be more than double, as many as thirty charges per week having been got out of a single furnace. In other processes of iron manufacture, such as steel melting, puddling, reheating, and welding, the application of water gas has been shown to have many advantages. The product has also been successfully employed in glass making. The plant in use at the Leeds Forge consists of two generators, a scrubber, and gas holder, with Root's blower and a steam boiler. The fuel used is common coke and coal; in fact the cheapest that can be procured. The product per ton of fuel is about 175,000 cubic feet of gas, of which from 30,000 feet to 35,000 feet is water gas, and the remainder high quality generator gas. The cost, including interest, depreciation, and supervision, is about 4½d. per thousand cubic feet of water gas, and about 2½d. per thousand of generator gas. When used for illuminating purposes the water gas is deprived of the small proportion it contains of bisulphide of carbon, which is regarded as the great bugbear of coal gas producers. It is this material which when burnt produces sulphuric acid, so disastrous to

gilding, pictures, furniture, and drapery, and so injurious to animal and vegetable life. Plants and flowers are said not only to exist, but to thrive in rooms where water gas is used as an illuminant. Moreover, the heat generated by water gas when employed for this purpose is set down at less than half of that given off by coal gas, and the entire absence of the heavy hydro-carbons in the latter precludes any possibility of smoky ceilings, as no free carbon can escape unconsumed from the water gas. The colour of the light stands midway between the electric arc light and the soft electric incandescent lamp. From the purple rays of the former and the yellow tint of the latter it is entirely free, and it more resembles the natural sunlight than any artificial illuminant yet produced.

The apparatus used for generating water gas is exceedingly simple, and entirely automatic in its action; indeed, any mistake on the part of the gas maker is impossible. Since the plant has been devised no case of accident by explosion has been heard of. As to its safety for domestic purposes, although the water gas usually made possesses no smell whatever, involving the possibility of an escape remaining undetected in the household, yet by an ingenious contrivance introduced by Mr. Wildy, a strong smell is imparted to it as there manufactured. This does not affect its illuminating power, but unmistakably proclaims its presence. A four months' experience at the Leeds Forge has shown the adaptability of water gas to the various uses mentioned.

Coming to the details of its manufacture, it may be stated that the apparatus used in its making consists principally of a generator, in which fuel, by means of a blast, is raised to a high temperature. Preferably the fuel should be of considerable depth. The blast having been turned off, steam is injected into the column of fuel, and the steam becomes decomposed, producing hydrogen and carbonic acid. This latter gas, in passing through the lower strata of incandescent fuel, is converted into carbonic oxide, which passes away with the hydrogen through the scrubber into the gasholder. The mechanical appliances by which the air and steam are alternately admitted, and the generator gas and water gas alternately led away, are cleverly conceived. One valve serves the double purpose of admitting the air and educting the gas. This valve slides on a three-ported face, connected with a chamber which is water-cooled. The valve itself is also cooled in a like manner, so that the intensely heated effluent water gas passes harmlessly over a common cast-iron surface without running any risk of damaging it. In the slide valve extra passages are cut in order to allow of the escape of the small residuum of air or gas which may be left in the passages or ports, and which, if allowed to mix, might cause an explosion. This valve is the invention of Herr Blass of Essen. The levers which operate this slide valve also move the blast valve, opening it when the slide is set for blowing the fuel and closing it when the slide is thrown over to the gas eduction port, and at the same time opening or closing the steam valve according to the position of the slide valve for gas-making or for blowing. The outlet for the generator gas is opened and closed by the same mechanical means, so that one lever, being thrown over, reverses the whole series of valves, and nothing is left to the possible absent-mindedness of the attendant gas maker. By this arrangement the risk of accident is completely obviated. The lower part of the generator, which is subjected to a very high temperature, consists of a single steel plate, flanged so as to form a cup. The ring made by this cup is continually full of water, this device preventing any destruction owing to the intensely great heat. It will thus be seen that the gas is produced intermittently. The rate of production is about 1000 feet per minute, at intervals of ten minutes. Each generator in use at the Leeds Forge is capable of turning out about 17,000 cubic feet of water gas per hour, with the consumption of about half a ton of the commonest and cheapest fuel. At the Leeds Gasworks a ton of coal produces 10,000 cubic feet of coal gas. The coke remaining after the extraction of the gas from the coal weighs some 13 cwt. or 14 cwt., and this coke will produce 23,000 cubic feet of water gas and 98,000 cubic feet of generator gas. In the manufacture of water gas at Leeds Forge canal water is used.

food in the soil than when it is practically sealed by a close soapy mass of little manurial value. The shoots must be regularly tied-in, allowing space in the ties for the swelling of the shoots. To assist the colouring and ripening of the fruits they should be exposed as much as possible to the influences of sun and air by removing or shortening some of the foliage where too thickly placed. Where the fruit is on the under side of the trellis the shoots may be untied and regulated, so as to bring them with the apex to the light, supporting them in position by laths placed across the trellis. Discontinue the syringing when the fruit begins to soften, and lessen the supplies of water, but on no account must water be withheld to the prejudice of the health of the trees. A piece of hexagon netting placed below the trellis, and so arranged as to form pockets to save the fruit from a long run against other, will prevent any fruit being bruised should they fall. Both top and bottom or side ventilation will be necessary constantly after the fruit commences ripening.

Late Houses.—There is more gumming of the growths than we have before experienced. The shoots are affected at the base of the current year's growth, and soon collapse. The most remarkable thing about them is that of their not being unduly vigorous. It is clearly a case of disorganised tissue through the cold in the early stages of growth not being favourable to assimilation. Growth so affected should be cut clean away below the gummed part and be burned. In autumn as soon as the wood, buds, and foliage are sufficiently matured lift the trees carefully, and before the leaves have fallen, preserving the roots that proceed from the collar with, if possible, some soil, laying the roots nearer the surface and fresh material or the old, adding a sixth of old mortar rubbish passed through an inch sieve, carefully removing any portions of wood as laths, &c. If the soil be light add a fourth of clayey marl in as fine parts as practicable. Make it thoroughly firm. Water if necessary; indeed, the soil ought to be in a condition for proper firming so that water will be necessary only to settle the soil about the roots, mulching with 2 to 3 inches thickness of rather rough and fresh or not very decayed manure. The lifting, the addition of calcareous and silicious matter, and the firming will effect a perfect cure. The blossoms will set, the fruit stone, and it will be perfected without stone-splitting. Continue syringing the trees as often as necessary to check red spider, but avoid keeping the foliage constantly dripping with moisture. Inside borders must be well watered and mulched. Tie-in the shoots regularly and evenly, keeping them rather thin. Stop any gross shoots, or preferably cut them clean out, thereby causing a diversion and more equalisation of the sap and vigour throughout the tree. When the fruit commences swelling after stoning close the house somewhat early in the afternoon, let the temperature rise in fact to 85° or 90°, ventilating a little before nightfall. Increase the ventilation early, and keep through the day from 75° to 85° whenever practicable. The fruit is so late that every possible advantage should be taken of the solar heat alike to perfect the current crop and the wood and buds for the ensuing season.

CHERRY HOUSE.—Let the trees now be as fully exposed to air as the house will admit. Remove the roof lights, which is the best means of arresting premature growth, to which the Cherry when forced year after year successively is liable. The leaves from their hard texture are not very inviting to red spider, but black aphides will prey upon them unless prevented by syringing or an insecticide. If black aphides appear at the points of the shoots syringe with tobacco water. The border must not be allowed to become parchingly dry, but have copious supplies of water, and if weakly employ liquid manure, as poverty of bud-perfecting means collapse of the fruit after setting if it get beyond the blossoming. Trees in pots must be regularly watered and syringed to maintain the foliage in a healthy state as long as possible.

CUCUMBERS.—These have been more crooked and stunted generally than we remember for a long time, due no doubt to the cold, wet, dull weather. In fine weather fire heat may safely be dispensed with, but in such dull and wet weather as we have lately experienced fire heat will need to be afforded to maintain a suitable temperature. Strive to preserve a healthy root action by a bottom heat of about 80°, keeping the plants well supplied with water but not in excess of the requirements, as a sodden soil is fatal to the activity of the roots, using liquid manure whenever vigour is required, or it is necessary for its maintenance. Let the plants be regularly examined once a week, removing the exhausted growths to make way for young bearing wood. Syringe moderately at closing time, doing so as early in the afternoon as the brightness of the sun, closing for a couple of hours to run up to 90° to 95°, then admit a little air for a short time to allow of the rank steam or moisture to escape, having the foliage fairly dry before nightfall, especially if fires are dispensed with. The Cucumbers for autumn fruiting should now soon be planted on ridges or raised hillocks moderately firm, maintaining a moist and genial atmosphere, and they will grow away freely and show fruit in plenty shortly.

Any frames at liberty may yet be planted with Cucumbers upon a bed of fermenting materials, which will give a supply of fruit in September, and continue up to near Christmas if due regard be had to lining the bed and to protecting the plants by mats over the lights at night in cold weather.

MELONS.—The weather has been of late anything but favourable, especially to late crops in frames, which have neither set nor swelled well, it being a remarkable feature that late Melons on dung beds grow very luxuriantly, and unless the foliage be kept thin the fruit sets very indifferently, and after setting refuses to swell. Some growers

FRUIT FORCING.

PEACHES AND NECTARINES.—*Late Succession Trees.*—Every attention must be given the trees in syringing to keep the foliage free from red spider, and in watering the inside borders. It will be an advantage to mulch the inside border with short somewhat lumpy or open material, as stable manure freed of the straw, but it must not be used in too great quantity at a time in the fresh state, or the ammonia vapour will seriously injure the foliage, particularly if the lights for ventilation are kept close, a little ventilation constantly being a safeguard against scorching, soft and attenuated growth. The value of using manure rather fresh as a mulch is that the ammonia given out is inimical to insects and invigorating to the plants, the waterings directly making it available for taking up by the roots, and by being lumpy or open atmospheric influences have freer access for effecting the assimilation of

object to the use of the knife amongst the plants whilst the fruit is setting, but we hesitate not to cut out superfluous growths whenever the necessity for it arises, and with the best results. Crowding the foliage tends to nothing but disaster. The blossoms do not set well, the fruit swells badly, and worse still, they have large seed cavities, are hollow, and have neither weight nor quality. Copious supplies of water are necessary to plants swelling their fruit about twice a week in bright weather, once a week or more distantly in dull moist weather. Sprinkle overhead at closing time, those in houses being well syringed both ways in the afternoon of bright days, and a good moisture maintained by sprinkling the floors, &c., two or three times a day, which will be all that is necessary in dull weather. Do not neglect to fertilise the flowers daily of plants now in bloom, and to go over the plants frequently for the stopping or removal of superfluous growths. Keep the atmosphere dry when the fruit is setting and ripening. Maintain a bottom heat of 80° to 85°, top heat 70° at night, 75° by day, in dull weather admitting a little air at that if there is a prospect of some sun, allowing the heat to rise to 80°, then admit more air, increasing the ventilation with the increased temperature up to 85° or 90°, closing sufficiently to raise the temperature to 90° or 95° or more. A free circulation of rather dry warm air greatly improves the finish and quality of Melons when near ripening. If canker appears at the collar promptly arrest its progress by rubbing quicklime into the affected parts, repeating as necessary, maintaining a drier and better ventilated atmosphere. If there be any indications of the fruit cracking cut the Vine about half way through a few joints below the fruit, reducing the supply of water at the root, and maintain a dry well ventilated atmosphere.

STRAWBERRIES IN POTS.—Runners intended for forcing should be transferred without delay into the fruiting pots. The plants for early forcing succeed best in 5-inch pots, or at most in 6-inch pots. Turfy loam, with an admixture of about a fifteenth of bone dust, is a suitable compost, giving preference to loam of a rather strong but friable texture. Pot firmly, keeping the crown of the plants rather high, and allow a depth of about half to three-quarters of an inch for watering. Stand the pots on a hard bottom imperious to worms, in a situation where the plants will have every advantage of light and air, and with due attention to watering and the removal of runners the plants will grow vigorously and mature the crowns early. Plants of the strong-growing varieties intended for successional and late forcing may have 7-inch pots. Plants that were layered into the fruiting pots should be detached after they are well rooted, keeping them well supplied with water, and remove the runners. They should be given a position after their removal from the layered quarters similar to those transferred from small to fruiting pots.

PLANT HOUSES.

Choisya ternata.—Plants that have been grown in frames since they were pruned after flowering will now be better outside. Plunge them in a sunny position, where they will have a chance of thoroughly ripening their wood, for upon this depends whether they flower well or the reverse. When kept under glass the whole season they invariably grow tall, are often imperfectly ripened, and consequently do not flower profusely. Be careful the plants have sufficient water at their roots. Soot water in a clear state is a capital stimulant for this plant, and adds to its beauty by the dark green appearance it imparts to the foliage.

Chorozemas.—This should now have abundance of air; from this time they are better exposed than under glass, only they need protection from such heavy rains as has been experienced lately. If bright weather follows use the syringe freely to insure the foliage remaining free from red spider. Water carefully, but do not allow the soil to become dry or serious injury will result.

Hardwooded Ericas.—Heaths may now be fully exposed, especially all the spring and early summer flowering varieties. Select a sunny position for them, and protect their pots from the burning rays of the sun either by plunging them or by securing round the pots on the sunny side old mats or bags, anything that will prevent the sun striking direct upon the pots and doing injury to the roots will answer this purpose. Water carefully while the plants are outside, but do not allow the soil to approach a dust dry condition, or their silk-like roots will perish and their leaves eventually will turn brown and fall.

Softwooded Heaths.—These also are better outside than in frames. Full sunshine is necessary to harden and ripen their growths if they are to flower well. The sun will not injure or brown the plants provided they have been grown cool and fully exposed. The only care that is needed is to protect the pots from the sun. If the plants are arranged in beds running north and south the front row and those on the west side only will need protection. The outer rows of plants will afford ample shade for all the other pots in the bed. The pots should be full of roots, and therefore liberal supplies of water will be needed. Keep the material on which they are standing moist by syringing liberally during bright weather.

Epacris.—The earliest plants have lengthened out good growths, and may be fully exposed the same as Heaths. Protect the pots and subject the plants to the same treatment. Late flowering plants may still be encouraged to grow by keeping them in frames. Abundance of air should be admitted during the day, but the frames may be closed in the afternoon at syringing time before the sun has passed off it.

Cytisus racemosus.—Young plants in 5-inch pots that are standing outside must not be pinched after this date, or they may not flower as freely as desired. If the shoots are allowed to extend they will become thoroughly ripened by the time they have to be housed, and are certain

to be a mass of bloom. Water freely and syringe liberally during bright dry weather.

Genetyllis tulipifera.—This and *G. Hookeri*, if they are to flower profusely, must have the wood thoroughly ripened out of doors. Protect the pots from bright sunshine, and be careful not to allow the plants to become saturated by heavy rains. *Boronia*, *Eriostemons*, and other hardwood greenhouse plants of a like nature may with advantage be exposed outside.

Acacias.—Those that have made a good growth may be stood outside after carefully hardening them. If the pots are full of roots weak stimulants may be given them. All that are restricted at their roots may be fed liberally to enable them to make a good robust growth.

FLOWER GARDEN.

Bedding Plants.—Very few of these have made any real progress; in fact, many of them do not fill the beds so well as they did when first placed out, owing to the decay of the old leaves and the formation of smaller ones in their place. Filling up with surplus plants has been largely resorted to in the case of *Coleus Verchaffeltii*, *Iresines*, *Alternantheras*, variegated *Pelargoniums*, and Tuberous *Begonias*. The three first named are the greatest sufferers from the long spell of wet weather, and it is doubtful if the *Alternantheras* will be very effective this season unless all blanks are filled in and rains warded off them in some way. *Lobelias*, *Ageratums*, *Pyrethrums*, *Violas*, and a few other of the hardier kinds are not so much injured, and may yet become more showy; but the Zonal *Pelargoniums* are in a sad plight, and in warmer weather will grow away strongly rather than flower freely.

Seeds to be Sown.—There are many hardy annuals and perennials which ought to be sown now or during August, in order that the plants may be of good size before the winter sets in. Those that should be sown at once are *Alyssum maritimum* and *A. saxatile compactum*, *Arabis alpina*, *Bartonia aurea*, *Saponaria calabrica*, *Silene pendula compacta*, both red and white, *Echecholtzias*, *Candytuft*, and such *Poppies* (*Papaver*) as *bracteatum*, *Marshalli*, *nudicaule*, *orientale*, *umbrosum*, and *pulcherrimum*. Towards the end of August sow *Calandrinia* in variety, *Clarkias*, *Corcopsis*, *Cyanus major*, *Collinsia bicolor* and *grandiflora*, *Erysimum arkansanum* and *Peroffskianum*, *Limnanthes Douglasii*, *Gypsophila elegans*, *Lasthenia californica*, *Virginian Stock*, *Venus's Looking Glass*, *Viscaria cardinalis*, and *Whitlavias*. The seed is best sown on warm borders, the soil of which is in good working order. Shallow drills may be drawn thickly, moistened if at all dry, the seed being sown thinly and covered with fine soil. The seedlings to be duly thinned out where crowded, and may either be transplanted in October to where they are to flower, or this important proceeding may be delayed till the spring.

Layering Carnations.—Propagation by layering is the surest and quickest way of securing a number of serviceable young plants of superior varieties, and which, it should be added, invariably produce during the following season much the finest blooms. Early in August is the best time to commence this important work. First loosen the soil about the plants, then surround them with a depth of 3 inches or more of good compost, nothing being better than a mixture of two parts of fine fresh loam to one of sifted leaf soil, with plenty of road grit or coarse sand added. Next select all the best placed young growths, trim off the lower leaves, and at a convenient distance from the main stem cut half through the under side of a joint, then give the knife an upward turn till a tongue about 1 inch long is formed. Next carefully peg them down so as to bury this tongue as well as the rest of the joints where cut in the fresh soil. It is of importance that these layers be prevented from springing out of the ground again; and to prevent this fairly long and strong pegs, such as may be cut from old birch brooms or Hazel wood, should be used. It is by no means a difficult operation, a very little practice being needed to give the desired confidence. In dry, hot weather, gentle waterings over the foliage may be given every evening, or till such times as the layers are well rooted, when they ought to be detached and either potted up and wintered in frames or planted out in fresh beds. Any border Carnations that have been flowered in pots are seldom of any service the following season, and these are the best to layer. They ought to be planted out either in cold frames or the open borders in sandy, loamy soil, as just advised, not uprightly, though, but in a sloping direction, this rendering layering a comparatively easy matter. See that the old balls of soil and roots do not suffer for want of water till such times as they have rooted into the surrounding soil.

Seedling Carnations.—Those raised last season are wonderfully gay at the present time, and will continue in full beauty for several weeks. Many strains include a good per-centage of handsome varieties; even the singles among them are very pretty and serviceable, and all are much more floriferous than named varieties from cuttings or layers. Plants obtained by sowing seed in April or May ought now to be of good size, or large enough for finally putting out in beds. The latter should be about 6 feet wide, raised a few inches above the level, and well drained. If the soil is of a medium loamy character, and the position somewhat sheltered, so much the better, though seedling Carnations as a rule are not very fastidious, and will often thrive in mixed borders, and other but slightly prepared positions. They should be carefully transplanted from the boxes or pans in which they were first pricked out, with the aid of a trowel, and be put out about 12 inches apart each way. Water in dry weather, and in showery weather look out for slugs.

THE BEE-KEEPER.

QUEEN SUBSTITUTION.

WE often see advice given to the effect that after queens have attained a certain age they should be removed and a successor given to the stock so deprived of its head. To some extent this is good and sound teaching; but as a correspondent in a contemporary points out, it is not after all the age of the queen at which we should look, but her fitness to remain at the head of the stock. Some queens are most valuable at an age when others are practically useless; others are at an early age only retained at a loss to the bee-keeper. True, many bee-keepers do not know sufficient of what is going on in the interior of their stocks to judge as to the fitness of a queen, and the advice to remove queens which have passed their third year is consequently in their case the most likely to be of practical value and generally useful, because the percentage of queens retaining their full vigour after three years' work in a large hive is, although larger than many have any idea of, still relatively small to the number which at that age are worn out. The age of every queen in the apiary should be known and a record kept of all changes. Any bee-keeper can do this, and if from his record he finds a queen past her third year—going into her fourth—a new one should be substituted, always supposing that the bee-keeper has no knowledge of the fitness of the queen apart from her age. Young queens, strong stocks, and a large surplus follow one another. The young queen enables the bees to rear brood in large quantities, and the increasing number of hatching bees enables the stock to still further increase in numbers at a rapid rate, with the result that when the honey season approaches a vast multitude of insects are ready to gather in the honey, while stocks headed by old worn-out queens are barely able to gain sustenance and to live on at all.

Added to these facts is the difficulty—often arising in February and the succeeding months—by reason of a queen giving out when it is almost impossible to give a successor. Even if an old queen does manage to tide over until the end of April the danger of the colony raising a new queen, and consequently sending forth a swarm, is increased tenfold from the fact that single queens are rarely raised, but there are generally several; and then when they mature, if the stock is strong, the first hatched queen leads out a swarm, or the old worn-out queen leads out the swarm, and one of the newly matured princesses remains at the head of the stock. In any case a great deal of extra and unnecessary trouble is occasioned by the neglect of ordinary precautions in the past; a little labour in due time saves much care and anxiety in the future.

Now comes the question whether it is better to rear queens or to purchase them, and it seems tolerably certain that there is no better method when such a course is practicable than for two or three bee-keepers to club together and raise the queens which they will require; the expense and trouble is thereby divided and less honey is sacrificed. Good queens are as essential to profit as a good season. There cannot be bees without a queen, nor can there be a surplus without good weather in which to collect it. Some bee-keepers carry on the system of stimulative feeding in the autumn to a dangerous extent. The queen is forced to extend her period of labour, and is thus weakened and becomes old before her time. Young bees are undoubtedly necessary to successful wintering, but they are sometimes obtained in a haphazard manner, which considerably militates against the success of the stock in the future.

At the end of the honey season, and especially in a season like the present one, breeding should be encouraged, but no food should be administered later than the last week in September in any circumstances other than when it is advisable to risk a lesser evil in order to avoid a greater. There is no excuse for the procrastination so often seen in putting up and preparing colonies for winter, and not an inconsiderable amount of the failure which bee-keepers

attribute to various causes is in reality the direct effect and the certain result of this policy of waiting pursued in the autumn. If feeding must be done it is just as easy to do it—in nine cases out of ten—at the proper time; but we cannot altogether forget that when the season has come to a close, especially in a year like the present one, the bee-keeper's enthusiasm is somewhat damped, and he becomes rather listless until the spring.

We are pleased to see that "A Hallamshire Bee-keeper" is going to revolutionise bee-keeping by the children of his fertile brain. We hardly see the point of some of his observations, although we seem to detect an attempt at irony. Surely a gentleman of "A Hallamshire Bee-keeper's" experience must be able to protect his inventions if they are new and worth the trouble and expense; and even if it is of no practical value to the bee-keeper of the future as to whether he was the gentleman who revolutionised bee-keeping or not, he will at least have the satisfaction of knowing that his genius has done something for which bee-keepers may have reason to be thankful, and for which every honest bee-keeper will be pleased to accord to him a meed of praise, even though the fact that "A Hallamshire Bee-keeper" is the inventor, and not some nobody, does not assist a bee-keeper in increasing the surplus which he will hope to obtain even more surely when these astounding inventions are thrown into the market. In the words of Milton, if we may slightly change them, we may expect that the result will be in future spoken of as a time when

"Earth trembled as if again in pangs,
And Nature gave a second groan."

—FELIX.

THE CALEDONIAN APIARIAN SOCIETY'S SHOW.

THE above Society, in conjunction with the Highland and Agricultural Society, held its annual Show on Tuesday the 24th, Wednesday the 25th, Thursday the 26th, and Friday the 27th July, on Glasgow Green. The weather was inauspicious, and the Show lacked the interest it formerly had. There was little honey and few competitors. There are reasons for the latter, and the unfavourable weather we have had answers for the former.

Very little of the present year's honey was shown, being mostly of last year's production, and had a better appearance than the new, which, according to the rules, was what only should have been shown. There was a class for granulated honey, the first prize being awarded to a mixed sample, some seemingly fine, but other jars very liquid and watery-looking, the second prize being awarded to a superior and uniform sample which, according to the schedule and our opinion, should have been placed first. The wine made from honey was, to our taste, too syrupy, and the beer too flat.

The comestibles made from honey were meritorious, but we think it is a mistake to make things from honey that does not improve the article as when made with sugar. If honey is employed in the manufacturing of anything it ought to be only when an improvement is apparent. Sugar is much cheaper than honey, and it is a want of economy to use it where sugar is cheaper and as good. Many things can be improved by honey and rendered more palatable than with sugar.

Observatory hives were well represented, but we think it a mistake to encourage others than the Unicomb, the only hive that scientific observations can be made from. Mr. Wm. McNally of Glenluce showed two hives of a novel description, which were neat and ingeniously made. One admitted the bees from comb to comb through openings in the sides of the hive covered with leather, which gave the bees access from one comb to another and did not kill them. The other hive was made on the principle of the "Lanarkshire" hive, but an omission in its construction to keep the combs together when one was hoisted was a grave defect, as when it was up and honey coming in the space would be filled with comb, and so render it an impossibility to lower it. With this exception, however, which will probably be remedied, the hive was much admired, and as the combs and brood were naturally and well covered with bees it was deservedly awarded the first prize.

Only two collections of appliances were shown by Messrs. McNally and Young of Perth, the famed makers of extractors and other tin appliances. Both collections were good, large and varied, Mr. Wm. McNally gaining first honours.

There was nothing novel and little to attract visitors inside, the greatest attraction being the bee tent, where driving was performed by Mr. Johnston of Touch, and lecturing by the Rev. J. B. Robertson of Stranraer went on simultaneously, which new feature added to the interest of the performance. But why keep on demonstrating the driving of bees—an obsolete thing in bee-keeping? And why preach the docility of bees with an awning of netting between the bees and visitors? If bee shows are to do good we should show how to manipulate bees under the modern system and with modern appliances, and without screens of any kind. Then will novices place confidence in both

teachers and bees; and while the most docile bees are taken as a type the public might be informed that there are some varieties not easily quieted, and when roused would not only put to rout the onlookers but a whole army. The whole truth and nothing but the truth should be told. It is misleading to say that courage and gentle handling are all that are necessary to handle bees with impunity. We hope that if this Society is to continue the prizes may be mostly distributed amongst the classes that require assistance, and who by the aid of bees may improve their condition by an increase of income, and that committees will encourage the uses of honey as hinted in the foregoing is the wish of all who view the matter aright.—L. B. K.

TRADE CATALOGUES RECEIVED.

John R. Box, Croydon.—*Catalogue of Bulbs and Plants.*

Lueombe, Pince & Co., Exeter.—*Catalogue of Bulbs and Roses.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (W. J. S.).—The address published in the work alluded to is correct, and the letter you have sent is posted accordingly.

National Rose Catalogue (Rosarian).—We are not quite certain on the point, but you can obtain the information by writing to Rev. H. H. D'Ombra, Westwell Viarage, Ashford, Kent, enclosing a stamped directed envelope for a reply.

Ham Green Favourite Tomato (J. L. D.).—This variety was raised by Mr. E. F. Crocker, The Gardens, Ham Green, Bristol, and is quite one of the best now ripening at Chiswick. It is a strong grower and free bearer of good sized and well shaped fruit.

Old Tan (J. T. S.).—We have received the sample. Such refuse would only be useful for improving mechanically very heavy soil, and as you have land of that nature we should give it a heavy dressing. It might render very heavy soil more suitable for Lilliums.

Vines for a Greenhouse (R. S.).—You had better confine yourself to four Vines in your 16-foot greenhouse, and for your purpose the Black Hamburgh will be the best. We think that from such a small house the profits from sale of the fruit would be very limited.

Aubrietias (J. A.).—Seedling plants may be planted any time during the summer, or slips of older plants may be put in during showery weather; but it is better to put them into some shady place to strike and then plant them out. Old plants, however, yield rooted layers or offsets, which do very well.

Young Laurel Leaves (A. S.).—The brown patches are occasioned, probably, by violent transitions of temperature. A sweet exudation is often found on the young stalks of Laurel leaves growing vigorously, and we have no doubt that the bees obtain honey from it.

Lucerne (B. E.).—This must be sown early in April upon well cleaned ground. Sow in drills a foot apart to allow the hoe keeping it clean. We should sow the whole 30 rods with Lucerne. Keep it well supplied with liquid manure, and you may cut it four or five times annually. A dressing with chalk or lime rubbish will be advantageous.

Asparagus Failing (A. O. S.).—We have not heard of a general failure of the crop this year. We recommend you to continue abstaining from cutting, and to give abundance of house sewage or other strong liquid manure twice a week throughout the growing season. If no shoots are produced, then, of course, the plants are dead, and you must plant afresh next spring.

Photographs (A. McDonald).—We received the photographs of Calceolarias, but if a letter was sent with them it must have slipped away unseen when the parcel was opened, and the only one received by post is dated July 28th. The plants were evidently fine, and must have been well cultivated, though they are not quite clearly represented.

Vine Leaves Falling (H. B.).—You supply no data whatever, either as to the nature of the soil or the treatment as regards temperature and ventilation to which the Vines have been subjected, to enable us to form a definite opinion on the subject. Their appearance suggests they have either been kept too close, or the border is too light, rich, and deficient in calcareous matter. The buds must suffer to some extent by the loss of the leaves. The leafstalks are too long, soft, and thin to be satisfactory.

Pelargoniums Dying (Crux D.).—The old plant sent is cankered at the base, a not unusual occurrence, and the origin not easy to trace. The wounds often heal over, and as your plant "grew all right" after you received it we suspect there has been some error in watering, or the position was unsuitable. If the cutting was healthy when inserted its decay after rooting is the result of some mistake in management. As you do not indicate where the plants have been kept, or the treatment they have received, we are unable to give a more precise reply.

Clematises for Beds (J. E.).—We have seen many varieties tried and many failures. When planted in mixture irregularity of growth results in patchiness, and eventually the weaker sorts are overrun by the stronger. For producing bold masses of colour the old and effective C. Jaekmanni is, we suspect, still unsurpassed, the growths being trained on wires fixed across the beds. Spring is a good time for planting, disposing the plants about 2 feet asunder. The temperatures given in the "Gardeners' Dictionary" as suitable for different plants are for day and night respectively by artificial heat, 5° or 10° increase by sun heat being allowable.

Mulberries Falling Young (H. D.).—As the tree produced a few fruits some years ago, we see no reason why it should not do so again. Most likely it is extra luxuriant from the roots getting down into the clay. Root-pruning would do it good, more especially as it has actually fruited. Female and male flowers are produced separately, just as in the case of the Cucumber. The former in small, ovate, erect spikes; the latter in a drooping axillary spike. Generally both flowers are produced on the same tree, but sometimes the flowers are nearly all males, and, in other cases, nearly all females. The check by root-pruning will encourage the pistil or fruit-producing flowers, more especially as they have previously appeared and arrived at maturity.

Trimming Ivy—Hydrangeas (W. S. S.).—The best time to "trim Ivy on the walls of a dwelling-house to look green again as early as possible," is towards the close of April, cutting it close with shears, and removing any accumulations of the old foliage with the hand. Fresh growths will shortly appear and be in good foliage in the course of a few weeks. Hydrangeas require only to have the shoots that have flowered cut back to where the buds are prominent in the axils of the leaves, and any weakly or elongated growths may be cut out or shortened, but only to plump buds, otherwise next year's flowering will be interfered with. In most cases it is only necessary to remove the decayed flower shoots. The plants must have sufficient water, and should be given a light and airy situation; so as to perfect the buds and wood.

Barrington Peach (E. F. C.).—The fruit and leaves sent resemble those of the Barrington, but your description of the flowers differs somewhat from those of that variety. We append the description of Barrington, and you can then perhaps determine the point for yourself:—Fruit large, roundish ovate, some of them terminated by a nipple at the apex. Skin downy, yellowish green, marbled with red next the sun. Suture well defined. Flesh yellowish, slightly tinged with red at the stone, rich, vinous, and of first-rate quality. Flowers large. Leaves with round glands. Ripens in the middle of September. The tree is very hardy, vigorous, and a good bearer. This is one of the best midseason Peaches, and bears carriage well. It was raised by a Mr. Barrington of Burwood, in Surrey, early in the present century. We do not find it mentioned in any nursery catalogue prior to 1826.

Eucomis punctata (G. J.).—It has large handsome spreading leaves, with their stalks much spotted and tinged with purple. It requires the same treatment, soil, and everything all the year round as Fuchsias. Gardeners grow Fuchsias in pots better than they would grow in the open border. But in an ordinary way Fuchsias do better planted out in a good border than in pots, and it is just the same with the Eucomis. Therefore, under your circumstances, the best thing you can do is to select a snug warm place for it out in the open air near to a south wall, or on a west aspect under a wall. To plant it there at once, as deep as it is now in the pots, or if not in a pot, to see the top of the bundle of roots is 3 inches below the surface. Give it water as often for the first month as if it were in a pot; after that it will do for itself, and the same sized heap of coal ashes which would save the roots of a cut-down Fuchsia from the frost will do to save the roots of Eucomis, but the leaves will go just like the tops of Fuchsias. Eucomis is a beautiful old-fashioned plant, and worth all the attention required.

Thinning Fruit Tree Shoots (F. J.).—The wet weather has induced growth quite abnormally. To prune hard under such circumstances is only to aggravate the evil, as it will have a tendency to induce late growth, which should be carefully guarded against by leaving the shoots a little longer than usual, and allowing some lateral growth to attract the sap, keeping it from starting the spur and other buds. To thin the spurs now is not judicious, but the shoots where crowded should be thinned to admit light and air for the storing of assimilated matter in the parts that are to remain permanently. It is too early to interfere with the roots of fruit trees generally, but any that are growing too vigorously and do not perfect fruit buds may have a

trench taken out around them deep enough to sever all roots, filling up the trench again firmly. About one-third the distance from the stem the trees spread is proper for the trench. It will probably cause the trees to form fruit buds. Allow one Strawberry layer to a plant, all others should be pinched off as they appear.

Club-root in Cabbages (*Amateur*).—It is in some cases very difficult to deal with. The best preventive is to dress the ground with gas-lime at the rate of a bushel per rod (30½ square yards) some months in advance of putting in the crop, for when applied at the time or shortly in advance of the planting it is injurious to them. It should be spread evenly on the surface, and be merely raked or very lightly pointed in. A dressing of nitrate of soda is also good. It may be applied a fortnight in advance of the crop, at the rate of 1 lb. per rod. Superphosphate of lime may be used advantageously at the rate of 3 to 4½ lbs. per rod. When planting out, any Cabbages found with a protuberance at the root should be thrown away, or the club opened and the grub destroyed; those and all the other plants dipped in a thick solution of soot water. Perhaps the best material for dipping is to mix 1 oz. Calvert's No 5 carbolic acid with two gallons of soapsuds, adding sufficient clay or loam to form a thin paste. Well stir the mixture and dip the whole of the plants before planting, which must be in damp soil, so as to render watering unnecessary. Petroleum may be used in a similar manner as the carbolic acid.

Bee Orchis Treatment (*J. R.*).—The *Ophrys apifera* may be grown in pots; which should be well drained, using pieces of chalk, and a compost of sandy loam, but not very light, intermixed with about a fourth of chalk in moderate sized pieces. The tuberous roots should be placed beside or between pieces of chalk, care being taken to fill in the interstices with the loam. The plants may be stood on ashes in a cold frame, but are preferably plunged in that material to the rim. They require to have the soil always moist, but little water will be needed during the resting period, whilst, when growing and until the growth matures, water must be afforded copiously. They are the better for slight shade. Admit air on all favourable occasions, and draw the lights off whenever the weather is mild. They may also be grown in pots plunged in ashes with a little protective material in winter, such as dry hay. A position where they will have plenty of light with slight shade from hot sun is the best for these plants. The best mode of culture is to plant at the foot of rockwork alongside limestone or chalk, with rock or other prominence that will afford shade from the powerful rays of summer sun. Care should be taken not to allow them to suffer from lack of moisture.

Ammonia for Vines (*R. S. T.*).—Time after time it has been stated in "Work for the Week," in articles, and in answers in this column, that ammonia can be beneficially applied to Vines in the form of strong guano water sprinkled in the house and placed in troughs on the pipes. We are most willing to advise you at all times, but have often observed you apply for information that has been given a few weeks before, and consequently a few weeks too late for your deriving full benefit from the replies that we can give on a subject. Mix one or two ounces of guano in a gallon of water, and make every available plant of the house wet with it every evening when you close the sashes. You cannot very well use too much of this in hot weather until the Grapes colour, but open the lights an inch or two at the top before nightfall, and the front lights also on sultry nights, and leave them open, giving more air very early in the morning in advance of the rising temperature—that is, to prevent the heat rushing up suddenly, then having to throw open the ventilators to reduce it. This latter practice, which is much too common, is the cause of many failures. The night temperature you name is quite 5° higher than is recommended in the Journal; in fact 10°, and we fear you do not read attentively. If the thermometer registers 65° the first thing in the morning the house will be quite warm enough, but there must always be a free circulation of air. Shallow vessels may still be kept filled with water in hot weather, but the ammonia applications had better cease when the Grapes are fairly colouring, and before they are ripe. As has frequently been stated, this should commence when the berries are about stoning.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. S.*)—The box did not reach us till Monday, and as it was only half filled with fruit the contents resembled jam, hence the varieties were totally beyond identification.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*P. D.*)—As you will see by our standing notification we do not undertake to name varieties of florists' flowers. Possibly most of those you send never had names; the flaked and mottled flowers are inferior. If you purchased the plants as named varieties you had better send flowers to the vendor for him to name. (*J. R. S. C.*)—*Melilotus officinalis*. (*W. K.*)—1, *Lotus corniculatus*; 2, *Medicago maculata*; 3, *Trifolium pratense*. (*W. B. R.*)—1, *Silene Armeria*; 2, *Centranthus ruber*. (*G. G.*)—We do not undertake to name Roses, and the other two specimens, both apparently *Spiræas*, were not in good condition for determination.

COVENT GARDEN MARKET.—AUGUST 1ST.

A brisk business doing, with heavy supplies. Prices remain the same with the exception of house fruit, which is lower.

A WET SUMMER.

AFTER the dry weather of May a dripping June was gladly welcomed, as being admirably calculated to promote free growth and bring on the corn crops in readiness to derive full benefit from the hot summer weather which we had reasonable hope would follow in July. But such hopes were doomed to disappointment, for the cold wet weather of July, 1888, was so remarkable that it will certainly be remembered for many years to come; not, we hope, for any disastrous results arising from it, but rather for its phenomenal character alone.

True it is that people are not wanting who assert that the effects of week after week of cold, wet, sunless weather in July must prove the reverse of beneficial for the corn; that the Wheat could not "cast"—i.e., set its blossom and develop grain—without

bright sunshine, and that such a summer must prove disastrous to corn crops. Well, now, we have several farms in hand in different parts of the great corn-growing district of East Anglia, and the superintendence of them, together with the management of wide-spread landed property, enables us to watch the progress of the crops and the effects of weather upon them, and we are bound to say that, so far, good rather than evil has followed a dripping July. The corn harvest must inevitably be late, but what does that matter if we get an abundant crop of corn and fine harvest weather? No doubt bright sunny weather is desirable when the corn is in bloom, but it is not indispensable to grain development. That depends much more upon atmospheric temperature than upon clear skies. As a matter of fact the mean temperature of the first week of July was rather more than a degree above that of the same time of year during the last fifty years, but the temperature of the second week was between 2° and 3° below it, and that of the third week was between 5° and 6° below the average. The fourth week shows a recovery of temperature, and an examination of the corn proves that the whole of it has "cast" very well indeed. Rye is almost ready for harvest; Barley is fine alike in ears and grain; Wheat is so forward that myriads of sparrows find plenty of food in the ears, and Oats show clearly that the process of ripening has already begun.

So far, then, the somewhat cold and showery weather has done no harm, except it be to the hay, but fine weather is necessary for the corn harvest, for sprouting grain is spoilt grain, and we heartily hope that a bright sunny August will send St. Swithin into retirement again. Peas and Beans have thriven wonderfully, nor do we find in these useful crops a mere abnormal straw growth, for pods are plentiful enough, and it must not be forgotten how invaluable Pea and Bean straw is for feeding sheep and cattle. We have now fair promise of an ample store of this valuable fodder, which dear-bought experience has taught us will prove invaluable next winter, and there is nothing more nourishing than Pea and Bean meal for live stock. Far better is it to have a good store of home-grown food for that purpose than to waste money upon impure oilcake.

The showery weather has undoubtedly made haymaking an expensive process, but the fact remains that good full flavoured hay can be made even in showery weather, and the bulk of the grass crop has been practically doubled by the rain. The good old rule of mowing grass for hay just as it is in full bloom has met with very little attention this year, but the thick growth of late grasses and Clover more than atones for some overripeness in the early grass, and the aftermath affords an exceptionally abundant growth of succulent grass. It is perhaps in the aftermath that the value of Cocksfoot in permanent pasture is best realised, for it starts into growth before any other grass, giving a strong free growth, of which both sheep and cows are especially fond. In this respect it is superior to all other grasses, and it answers as well for hay as any; better than most, we might assert, if bulk alone is considered.

Root crops of course thrive apace in such showery weather, yet even of such crops we have heard it said that they are now making leaves at the expense of roots! Yet we never heard even the most pronounced grumbler assert that large roots had not fine leaves. Cabbages and Kale ought to be abundant enough next winter if only the land has been well cultivated. We have ample evidence that it is the year of years for chemical manures, and the crops to which such manure has been applied show by an exceptionally vigorous growth that the busy roots have not suffered the nitrogen to be washed out of the soil.

WORK ON THE HOME FARM.

The corn harvest will be so late that there will be no stubble Turnips this year, nor shall we require them, for we were able to get fallow land so clean in May that it lay ready to our hand for sowing successional root crops in June and July. The last sowings of White Turnips have been made, and there will be plenty of lamb food from them next spring. Rye is almost ripe enough for mowing, and winter Oats will follow closely, for when the grain changes from the juicy or milky stage no time should be lost in mowing, or there will be risk of much of the

corn falling. On small farms where space is so precious that close cropping has to be practised, Turnips have been sown after Tares, and have come well. Rye or Oat stubbles will be broken up early for winter Tares, which if sown early often give a very valuable supply of green food early in spring, to which we may turn after the Rye folding is done.

The showery weather has induced so strong a growth of young Clovers and mixed layers among corn that it is likely to prove troublesome in harvest. The only way to avoid trouble from it is to mow high and leave long stubbles; this involves some loss of straw, but it ensures the expeditious harvesting of the corn, a matter of especial importance with Barley, which suffers a serious deterioration in value from discoloration by rain. Some of the heavier Barley has become lodged by high wind and heavy rain, but we have not seen this to any great extent. On the whole, it is remarkable how well the corn stands up in the stormy weather we have had lately. This may in some measure be accounted for by the unusually robust growth of straw caused by the wet July. At one time the straw growth promised to be very dwarf, but straw and grain are now alike abundant.

Haymaking will now soon be finished. It has proved a tedious, expensive, and arduous undertaking, but as usual watchfulness and care have enabled us to make good hay without bright sunshine. Haycocks have enabled us to overcome weather difficulties; without them the hay would have been spoilt. Greatly do we regret to find so many farmers without poles, blocks, pulleys, ropes, and suitable rick cloths to protect the ricks from rain. Many who have rick cloths simply throw them over the rick at night, but that is most objectionable, as it neither throws off the rain well nor admits of a free escape of vapour from the rick.

OUR LETTER BOX.

Liver Fluke in Sheep (M. S.).—A wet spring and summer frequently causes both sheep and lambs to suffer from liver fluke. No disease to which sheep are liable is more difficult to overcome. Out of fifty lambs purchased at a July fair in a wet season we lost fifteen despite all our care. We have also had heavy losses of sheep by it. During the earlier stages of the disease the animals fatten quickly and the mutton is excellent. When sheep are attacked by it, the only way to avoid loss is to force them on by high feeding, so that they may be killed and sold while the meat is wholesome. Lameness of the right foreleg is the first unmistakable symptom. If the sheep is then caught and pressed upon the right side it shrinks with pain. As the disease advances the eye becomes suffused with yellow; the skin also becomes yellow, the wool parts easily from it, and then death usually follows quickly. The remedy, or rather the best method of treatment, is to put the flock upon a dry upland pasture; to give dry food, consisting of chopped hay mixed with crushed oats, bran, and a little cake, with a plentiful mixture of salt. Bock salt is also kept constantly among the sheep. A tonic consisting of a drachm of powdered gentian root with half a drachm of powdered ginger may also be given frequently with advantage.

Books (H. B. M., Canada).—"The Complete Grazier and Farmers' (&c.) Assistant," by Youatt & Burn; Crosby, Lockwood & Co., 7, Stationers' Hall Court, Ludgate Hill, London. £1 1s. "Handbook of the Farm Series," nine vols. at 2s. 6d. each; Bradbury, Agnew & Co., 9, Bouverie Street, London. "Principles of Scientific Elementary Agriculture," by J. C. Buckmaster and J. J. Miller; Simpkin, Marshall and Co., London. 1s. 6d. "Wrighton's Handbook of Agriculture," Collins, Sons & Co., London. 2s. This set will suffice to give an all-round idea of general agriculture. Thomas Jamieson, Esq., 173, Union Street, Dundee, is the address to which you may apply for the other pamphlets.

REMARKS.

22nd.—Very fine fresh morning, and pleasant day, without much sunshine. Heavy rain from 10.30 to midnight, with lightning and thunder.
23rd.—Overcast and threatening, with distant thunder until about 11 A.M., then fine and generally sunny.
24th.—Gale all day, occasional rain squalls in the morning, otherwise generally bright.
25th.—Wet all day, fair evening.
26th.—A thorough specimen of an April day, bright sun and heavy showers alternating.
27th.—Bright till 10 A.M., showery till 11 A.M., then fair with occasional sun. Some rain in afternoon, and heavy rain from 6 to 7 P.M.
28th.—Generally fair, but slight rain about 7 P.M.
Temperature near the average, but owing to cloudiness the range has been small, the nights have been warmer and the days cooler than usual—in fact, the highest during the week was only 72.4°. Rain again much above the average.—G. J. SYMONS.

VIOLAS.

FLOWER garden plants that will endure the continuous rain of a season like the present possess a value which all can appreciate that have large beds and borders under their charge, and which are expected to have a gay appearance at this time of year. The conventional bedding plants of the Zonal Pelargonium, Calceolaria, Verbena, and Lobelia types, have had a bad time, the best arrangements and the best prepared plants having in the majority of cases failed to give anything like satisfaction. It is now becoming too late for them to do much good, and many gardeners have quietly resolved not to depend another season exclusively upon one class of plants for garden decoration. Even Tuberous Begonias, which seem to be the most independent of weather conditions, are much retarded this season, and are only just commencing to reveal their true character. A few weeks' bright sunny weather will, however, suit these admirably and furnish the borders with all the brilliant tints which the Pelargoniums have been struggling in vain to produce. Some of the hardy herbaceous plants have resisted the torrents satisfactorily, but all with delicate soft-tinted flowers have been sadly damaged, while in our Rose gardens we have had to snatch a flower here and there amidst a melancholy array of unexpanded or decaying buds.

Few plants can be compared with Violas and Pansies for rain-enduring constitution, and though we have had to lament the loss of scores of valued favourites amongst other plants, these have not only defied the weather, but have actually seemed to luxuriate in the abundant moisture. It is true growth has been a little drawn and weakly in some instances, but the numbers and prolonged succession of the flowers have more than compensated for this in such a summer of floral dearth. Respecting the value of Violas more particularly we have been strongly reminded by the arrival of a varied collection of flowers from Mr. Wm. Dean of Solihull, most charmingly representing their astonishing range of colouring. Violas cannot be ranked amongst neglected plants in the same sense that many others can, but possessing such important qualities and so much variety, they ought unquestionably to be much more largely planted and more frequently seen in gardens. Why, for instance, as remarked by a correspondent, do we so seldom see them in the public parks or gardens? Occasionally a mixed bed in which *Viola cornuta* is employed attracts attention, but no attempt has been made to adequately represent the beauty of these plants. In beds of one variety, mixed, or as margins to other plants, for which they are especially adapted, they have a delightful effect.

It cannot be urged that any difficulty is experienced in securing distinct varieties, for there are now some scores of charming forms to select from, including the richest and the most delicate tints. Mr. Dean sends us about fifty varieties, of which the following may be mentioned as the best in the respective groups. Commencing with the purple selfs, or those in which rich velvety purple tints predominate, very notable is Sir Joseph Terry, a new variety that is not less remarkable for its depth of colour than for its compact habit and free flowering. Topsy also is good in colour and free, but being of more spreading habit is better for large beds. Two beautiful seedlings from the well known Chiveden Purple are named respectively Queen of Violets and Queen of Purples, both more compact in habit and more profuse than the parent variety.

Amongst blue and lilac Violas True Blue is one of Mr. Dean's

raising, and a first-rate bedding variety, the colour a bright blue purple, of fine compact habit, sturdy constitution and exceptionally profuse. Navy Blue is one of the Blue Bell type but superior in habit and colour, Archie Grant being a favourite rich dark blue, and Queen of Lilacs a capital variety for large beds, the flowers of great size, lilac, with rich blue veins and a gold eye. Lilac and lavender tinted Violas, such as Duchess of Sutherland, Fairy Queen, and Elegans, are generally seen to better advantage when the weather is not quite so trying, but all are good, and especially the last-named, which should be freely employed in bedding.

White-flowered Violas are not very numerous, and they are usually rather disappointing, many so-called pure varieties coming splashed with colour, or of a dull dirty creamy hue. In Countess of Hopetoun we have, however, one of the best yet raised, the flowers of good shape, free from all markings, compact, and profuse in flowering. In contrast with some dark purples or velvety blues this variety is excellent. Mrs. Smith is another of the same type, but with larger flowers and a few fine rays in the centre. Mrs. Gray surpasses the other two in strength of habit; its flowers also are admirable in shape and size, possessing an agreeable fragrance, but in some seasons the flowers come tinted or streaked with pale purple.

The yellow-flowered Violas afford some useful bedding varieties, a trio of deep yellow forms being Bullion, Golden Prince Imperial, and Lutea profusa; while of pale yellows Ardwell Gem, Golden Prince, Queen of Spring, and Golden Queen of Spring are equally good in all respects. The "striped and clouded" group is a large one, comprising some of the most handsome varieties in cultivation and the most telling in borders. Such, for instance, as the well known Countess of Kintore, purple and white; Rosebud, crimson and purple; the Mearns, deep crimson and purplish mauve; and Mrs. Baxter, rosy purple. Other beautiful varieties in the same group are Mrs. Henry Child, violet and blue, shaded light at the edges, a charming novelty; Mrs. Tosh, Mrs. Brodie, Pytho, Spotted Gem, purple and white, and Ethel Baxter, rosy purple with a lighter edge. The fancy Violas include several very peculiar and distinct varieties, Blue Cloud being a novelty of much promise, creamy white edged with deep blue; Goldfinder, yellow edged mauve, is peculiar, but not so beautiful as the preceding; Bronze Queen and Dawn of Day both deserving mention.

Seven new varieties just to hand from Messrs. Dobbie & Co., Rothsay, must also be noted here, as they are of exceptional merit, having been raised by Mr. Baxter of Daldowie. In all the flowers are of good size and shape, the colours particularly rich. Gipsy Queen, lilac streaked, delicate and distinct; Hugh Ainslie, an improvement on Duchess of Albany; Sunrise, the upper petals soft rose, the lower rich crimson streaked with purple, gold eye; Queen of Scots an improvement on Countess of Kintore, deep violet centre, fading to nearly white at the edge, gold eye; Lady Gertrude, of The Mearns style and considered better, lower petals rich purplish crimson, upper pale blush or rose; Lady Ashton, lower petals creamy white, upper deeply bordered with rosy purple; and Crown Jewel, deep maroon with a wire edge of creamy white, most effective, and extremely rich.

Mr. W. Dean's remarks on the culture of Violas may conclude this article, and are well worth consideration:—

"The Viola is easily propagated, either by cuttings during August, September, or October, and later, or by rooted offsets. Cuttings can be put in early on a shady border and kept damp in dry weather, no glass being necessary. In the southern, western, and more favoured districts Violas will stand well out of doors during the winter, but in cold wet districts and very exposed situations, and in the Black Country districts, it is best to keep young plants in cold frames, when they can be fully exposed to the weather, excepting in very severe weather or drenching rains. Use plenty of drainage, 6 inches to 8 inches of good soil, and the plants near the glass, and from 2 inches to 3 inches apart, so that

they can be lifted with balls of earth and planted out in favourable weather in March or early in April. Let them have plenty of air through the winter excepting in bitterly cold or hard weather.

"For planting out, prepare the soil in winter by the addition of well-decayed manure—cowdung if it can be had—and have the ground in readiness for planting in March or April. If autumn planting is adopted, and when it can be done I recommend it, prepare the ground as already indicated, and plant out in October or November, so that the plants may get a firm root-hold before winter set in, and mulch with leaf soil, decayed dry manure, or some other material, keeping a reserve stock to make good any failures through the winter. Both for *Violas* and *Pansies* a position where they can be screened from the intense heat of the mid-day sun up to three or four o'clock is most beneficial in preserving the blooms and the plants. Watering with a fine-rose pot night and morning, and even oftener, is beneficial; and by doing this freely this season I effectually kept down the brown aphid, a most destructive pest. Old shoots when they have ceased blooming should be cut away, and two or three times during the summer some good soil should be placed in and about the plants and long growths pegged down. If *Violas* and *Pansies* are kept growing in vigorous health, the brown aphid—a terrible enemy—is beaten, and the plants kept free from it; but the plants should be watched for this pest, a very small variety of the green fly, then apply tobacco water or some other well known solution."

We shall be glad to receive contributions from any correspondents on this subject.

VINES—AERIAL ROOTS.

It is a generally accepted opinion that the roots produced by the stems, rods, or canes of Vines are different from these in the border. The only real difference, however, is that one is formed on that part of the Vine which is above ground, and the other on the part within the soil. Both are emitted whenever the conditions are favourable to their production. The root, or descending axis, differs from a stem through its origination, it does not ramify or branch symmetrically, and is devoid of normal leaf buds. A portion of the matter transmitted to the stem and the foliage to be elaborated and assimilated must descend and be stored corresponding to that stored in the young wood or cane, so that the roots become more or less of a ligneous character, which is proportionate to the maturity of the stem. If the growth is soft, long-jointed, and distinguished by a large pith, the roots are correspondingly soft and bare of rootlets, being more liable to collapse under adverse circumstances, as is unripe wood, through vicissitudes of climate, than thoroughly solidified and matured.

As the value of wood for fruit production depends entirely on the food stored therein, so with roots. Their preservation or continuance through the resting period is dependent on the measure of their maturity and material stored therein. The object of the cultivator with recently planted Vines is to produce as much growth as possible, in order also to have an increase of roots. A large amount of growth may be produced with very little mature wood and less stored matter than in canes that have not made a quarter the growth. The latter, through being required for fruiting, are kept somewhat closely pinched, more of the aliment absorbed by the roots and elaborated by the foliage being assimilated and stored alike in the cane and the roots. The wood of the last is brown and hard, the buds are well developed and prominent as nuts, the roots from their ligneous nature are retained during the resting period, prepared to emit fibres abundantly when the buds are called into activity. The wood of those that are to be cut back to the bottom of the trellis or rafter is for the most part unripe, the roots are of a spongy nature, and the greater part collapse during the resting period; the consequence is the Vines have not the benefit of as many active feeders in the early stages of growth as those treated in the previous year, so as to insure sturdy thoroughly solidified growth, properly elaborated and assimilated sap, or perfectly developed buds on properly matured wood. To encourage growth, therefore, in order to form roots, is not good unless means are adopted to so expose the foliage to light as to insure a descending current of assimilated matter to the roots.

It is essential that Vines selected for planting have a sturdy habit, short-jointed thoroughly solidified and ripened wood. Such I am well aware are not preferred, but the best and most thoroughly perfected are retained for fruiting in pots. Why? Is it not

because canes with thoroughly ripened wood have roots of a more ligneous nature, more food being stored in them than those that have longer jointed, less firm wood, with larger pith, with roots very much less numerous, more fleshy and watery, there being very little ripe wood? Thoroughly ripened wood and ligneous roots stored with material give Vines their value for starting at an unnatural season. The early growths are supported by the stored up sap in the stem, still further supplemented by that in the roots. The Vine with short-jointed, stout, thoroughly perfected wood and plump buds, has sufficient roots to meet all the demands made upon them by fruiting without having recourse to adventitious or aerial roots. The case is different where the canes are long jointed, thick, having a large pith, and only the semblance of ripened wood, very little stored material being available for the support of the growth and the development of the fruit. The roots are long with thick ramifications, and they do not transmit food in sufficient quantity for the support of the foliage and developing fruit, as the stored up matter in their case is soon exhausted. In pot Vines adventitious roots appear at the collar or above it on the wood of the previous year of cut-backs, and given surface dressings these will soon extend over the pots into the plunging material, proving themselves true roots. This, however, is hardly applicable to Vines generally, as aerial roots from Vine stems or rods cannot well be supplied with material from which they can draw supplies supplementary to those afforded by the border roots.

If aerial roots are false our present system of growing Grapes is false also. It may be a bold assertion, but I venture to state that there is not one Vine in a hundred that is on true roots if aerial roots are false, which is not the case. A Vine at planting may be everything desired—viz., have short-jointed, thoroughly solidified and ripened wood, with a mass of roots emanating from the collar or immediately beneath the soil, and yet be ruined by the practice of planting so as to bury a good part of the cane in the soil as well as the roots. The idea, no doubt, is to increase the amount of roots from the part of the cane buried, and these roots, adventitious and corresponding to aerial, strike down or mostly proceed from the under side of the cane buried, the soil not being firm, or it may have shrunk so as to leave a cavity or looseness of compost next the wall; in any case, these roots strike deep in to the border, laying the best possible foundation of unsatisfactory crops of Grapes, with a certainty of abundance of aerial roots. A properly planted sparse-rooted Vine in a properly formed border may furnish itself with roots from the collar, which, proceeding laterally, will extend through the border near the surface, cultural requirements being afforded for their keeping, so that they are better than those consigned to disaster through burying the original roots along with a portion of the cane at planting. Objection may be taken to this on the ground that Vines so planted sometimes prove satisfactory. I am well aware of the fact that such Vines do splendidly for a few years, whilst the border materials are open, admitting the free access of air and rain and water; but how many years elapse before the Grapes begin to shank and finish indifferently? Take a Vine with two rods, both trained alike to the roof and having the same advantages up to the first indication or appearance of aerial roots; bring one rod down so that it can be buried a few inches deep in suitable compost. It will at once solve the problem as to the character of the roots by the additional vigour the growth on the rod speedily assumes; the finer berries and better finish of the Grapes, with something to spare for its companion rod, which will follow the lead and partake of the other's prosperity. The rod should be layered somewhat in advance of the growth or before the buds break, as from the contact of the rod with the compost roots will sooner be emitted, but they will not be at all freely catering until the Vine is advanced in growth very nearly if not quite up to the flowering and setting period. This I have proved by layering canes into pots, lengths of 12 feet or more, with the pots as close as they could be. The buds started with those from spurs on the rod, but roots did not push freely from the part of cane in the pots until the shoots had shown and developed the bunches, being well advanced for flowering and even set before the shoots began to start away with a bound, a clear indication that the roots were in possession of the soil, and sending up the aliment provided by applications of liquid manure or water passing through mulchings of rich material. Each shoot or cane left alone soon attains sufficient length and strength for a fruiting cane of the first order for another season's forcing, and instead of impoverishing the Vine they are a source of invigoration as long as they remain, and for some time after detachment the good effects continue, though there is a diminution apparently of benefit from the time of the detaching of the pot canes from the Vine.

Now let us lie back to the consideration of the two descriptions of Vines—viz., the short-jointed stout wood well ripened, with

roots fibrous and abundant near the surface, stored above and below ground with thoroughly assimilated matter; and the long-jointed, link, coarse-jointed, and large-pithed, with roots somewhere, but not near the surface, full of watery unassimilated matter both above and below; or that description of Vine which from poverty of resource in making wood and roots are strawy; and how do they act in respect of aerial roots? They act as regards the first well, and as regards the other badly. In the first there is abundance of stored sap in firm thoroughly matured parts, which are not liable to loss to nearly the same extent as the other under disadvantageous conditions; the roots are more numerous and much more ligneous, consequently many more or the greater part of those annually formed survive, and consequently push roots sufficient for the supply of nutriment. There is little or no emission of aerial roots unless there be an advantage in growth through greater geniality than the roots enjoy, which is clearly an error or mistake of culture rather than resulting of anything particularly wrong with the Vines, and that is soon rectified by recourse to more suitable treatment. The presence or otherwise of aerial roots is resultant of inadequacy of aliment proportionate to the condition of growth. Restore the reciprocal action between the roots and head, and aerial roots will cease growing without any disadvantage to the growth other than a tendency to check it and insure its solidification. The other description of Vine will, if examined, have very few and thick soft roots, fibres absent or much damaged, being made late and soft, as are the growths, and they collapse during the winter, shrunk if dry, or decayed if wet. Nothing is ripe to insure their preservation; they suffer more loss by annual decay of the roots than those that are firm and ripened. The Vines start badly, the rods must be kept dripping with moisture and the atmosphere like a stew pan to induce the buds to move, with the result that tissue-paper-like foliage is formed, becoming flaccid under sun, and the bunches twist and curl. The Vines push aerial roots from the stems, rods, and spur stems—every part in fact where there is or has been a deposit of the assimilated matter—and these afford a temporary relief to the Vines by taking from the atmosphere the elements they are insufficiently supplied with by the roots. These roots remain until there is enough formed in the soil to meet the requirements of the growths, when they begin to wither and ultimately shrivel alike from the better supply of matter from the roots in the soil and the drier treatment accorded the Vines, which it is needless to point out, is not favourable to the extension and continuance of the aerial roots.

It must not be overlooked that Vines outdoors do not emit aerial roots nearly so frequently as those under glass, but it is not a question of degree, but of why they emit aerial roots at all. If it be moisture with geniality of climate favouring more growth than the roots proper can adequately support, my argument falls to the ground, and we have only to maintain a drier atmosphere to prevent air roots appearing, we having instead thoroughly solidified growth from the commencement, continued all through until we have wood and buds perfected and stored down to the root tips. With Vines in that happy state aerial roots need not cause anxiety to the cultivator, as with rational treatment they will keep on their even way for nobody knows how long. Whenever aerial roots appear from almost every part of the stem, and particularly where the spurs diverge from the rods at the base of canes on the ripened, or wood of the previous year, then be sure that the time has come when the roots in the border are not equal to the supply of nutriment the Vines require. No time should then be lost in preparing materials, such as clean drainage and suitable compost for forming a fresh border, in which to lay the roots nearer the surface when the growth is sufficiently matured for its performance. If the Vines have nothing but bare thick roots with a few small ones at the collar, it may be a question as to whether it would not be better to make a fresh start, planting Vines that are well furnished with roots, letting the after treatment be such as will preserve them, and then there will be no occasion to interfere with them other than to afford food supplies, or crude material for its manufacture.—G. ABBEY.

NOTES ON CACTUSES.

SOME thirty years ago I was garden boy in a fine old garden under a fine old Yorkshire gardener. He was a stern master and was called one of the old school. I have always considered him to be the best gardener under whom I ever served, as in spite of his natural sternness he was more communicative than the majority of head gardeners were in those days. Might I say a word in the behalf of the young men of the present day? That the majority of "head" gardeners are anxious as to the future welfare of the learners under them admits of little doubt; still, if we are to believe all we hear and see, there are easies to the contrary. That kind words of encouragement are not always thrown away requires no proving.

They tend to give confidence and to engender an interest in the work to be done. I will not digress further, but will revert to the heading of my paper.

I was at the date named employed in weeding garden and pleasure ground walks, except on wet days, when I had to go into the houses, and nearly always had the same task set me—namely, cleaning Cactus plants. When the old gardener gave me orders what I was to do he always ended with the strict injunction, "Mind don't knock t'pricks off." Having the same task repeatedly, I had a fancy that the regular workers in the houses had an objection to these peculiar plants, it may have been on account of the spines. At all events I became familiar with the plants, and when one day I was told by my old master that I was the best hand at cleaning Cactus that he ever had I was more than ever interested in them. Not long after I was promoted to the charge of some houses; they became my favourite plants, and I may add they have remained so to this day, and at the present time, although I have under my charge a goodly number of plants in considerable variety, including Orchids, which seem to be the fashionable, and I fully recognise their usefulness and beauty, yet my love for the striking, twisting, and stunted masses of vegetable matter of the Cactus family remains predominant. That this is a neglected class of plants cannot be denied, for although I have under my charge a collection that can be counted by the hundred, yet hundreds of gardens may be visited, and members of the Cactus family not be seen, excepting perhaps Epiphyllums, and they deservedly have held their own in most gardens.

It would be somewhat difficult, for me, at least, to state a reason why the plants under notice are so seldom seen. It cannot be on account of the difficulties in their culture, because none exists, whilst their gorgeous flowers rival in beauty and variety of colour the majority of flowering plants. Certainly they are not so chastely beautiful as the majority of Orchids, neither are they so costly. One objection that I have heard levelled against Cactuses is that the flowers are short-lived. Certainly they do not last so long as those of many other plants, still a continuity of blooms may be had over a long period. Some of the plants under my charge commenced flowering in April, and we have not had a break of a single day up to date; and although the blooms naturally become less numerous as the season advances, we hope to have occasional blooms well into August, which means Cactus flowers for about five months. Some of them are deliciously scented, and many colours and forms are represented, from the tiny Mamillarias in thumb pots to the magnificent *Cereus* in large tubs.

The Night-flowering Cactus, *Cereus grandiflorus*, is one of the most popular of the whole genus, and should be grown in every garden, for although it is generally supposed to require a stove temperature, it will nevertheless succeed fairly well in a minimum temperature of 38°. This species is mostly to be found growing up a wall on which moss is fixed by some contrivance, so that as the stems ramble over the surface the roots from them take possession of the moss, which, when the plant is growing freely, should be kept moist by syringing. In such a position it flourishes admirably, but we prefer to grow this *Cereus* in a smaller compass, so that when the flowers appear we can move the plants about at pleasure, and instead of the ladies having to leave the drawing-room at night to see the flowers, we can carry the plants to the room to see the ladies. Plants grown on this, what I shall call restricted system, are therefore much appreciated. Six to ten-inch pots are used, and plants in such pots will, under attentive cultivation, carry from one to four blooms respectively. Three or four sticks are placed in each pot, and as the growths extend they are trained round them. Another plan I have found to answer well is to have galvanised iron stakes and ordinary small-meshed galvanised wire netting put round them, forming a sort of cylinder, which is filled with moss into which the plants root freely.

The compost used for this plant is sandy loam made very porous by adding a sufficient quantity of pounded bricks and pieces of charcoal, and when the plants become well established and in full growth liquid manure is applied in a diluted form two or three times. No manure is mixed with the soil, as from experience I am satisfied that the plants succeed better without it. The judicious use of water is absolutely necessary to ensure success. When in full and active growth give water freely, and place the plants in a somewhat shady position. When growth is completed place them in the full sun, and give water less often. When the stems assume a reddish hue it is a sure sign that they are ripened, and little or no water should be given until the spring, when signs of growth are again apparent. It should then be given with much caution, only sufficient to prevent shrivelling, or flower buds will not appear. As soon as these buds are safely formed more water may be given, but always with thoughtful care, especially if the plants are in a low temperature, cold and damp being fatal to the roots. To propagate young stock after taking off the shoots lay them on a shelf in the

full sun, so that the cut part may get dried or healed. They should then be laid (not inserted) on some damp moss or cocoa-nut fibre refuse, when roots will be emitted in a short time. They can then be potted in the ordinary compost as advised above. The spring is the best time to propagate, just as the plants show signs of starting into growth.

Cereus McDonaldiae is another night flowerer, and although not so popular as *C. grandiflorus*, it is according to my fancy the most magnificent of all. The blooms are larger, often being 14 inches in diameter, but they lack the delicious fragrance of *C. grandiflorus*. Plants can easily be grown and flowered on the portable or restricted system. *C. rostratus* and *C. triangularis* are both of a rambling disposition, and produce handsome flowers, the latter species being an object of special interest when seen bearing its large-sized highly coloured fruit, which show to the best when trained in some way overhead. Both those decline to flower on the restricted system. *Cereus speciosissimus* produces the most brilliant coloured flowers imaginable, is of easy growth, and very free. It is probably better known than any other member of the family, with perhaps the exception of *C. flagelliformis*, called by cottagers the Rat's-tail Cactus, and good plants may sometimes be seen in their windows. *C. Mallisoni* is also well worthy of general cultivation, producing its bright rosy crimson flowers freely when in a small state, or it may be trained up the rafters when its flowers may be seen to the best advantage.—W. C.

(To be continued.)

CROPS THAT PAY.

TOMATOES raised from seed sown towards the end of April and brought forward under glass, however rude the structure, will grow strongly and sturdily from the first. This is the condition in which plants should be if the object the cultivator has in view is to be attained—namely, a good crop of fruit. When plants are drawn weakly in a close atmosphere they are too soft, and considerable time is lost before they attain the solidity necessary to insure a good set. But when raised under cool conditions, and advanced without further artificial aid than cold frames afford until the weather is sufficiently genial in June to turn them outside, they generally give every satisfaction. So far the season has been unfavourable, and too cold for the well-being of Tomatoes. A week or two ago, what with wind and cold, the plants presented a wretched condition, but they are again growing vigorously. The growths are strong, but too soft to insure a good set from the base. However, if fine weather sets in, reasonable success may be looked for, and if the plants will set their fruit the object we have in view will be attained. It is immaterial how small the fruit is when the plants are housed in September, provided they are not left out until they have been checked by cold.

The easiest mode of raising Tomatoes for this purpose is to prick them out in frames in 3 or 4 inches of moderately light soil on a firm base, so that they can be lifted with good roots, transferred to 6-inch pots, and from these to 10-inch, or direct into the latter size. The latter is the most economical system, and this can be done in June when the plants are turned outside. In a few days, or a week at the most, they become established, when they should be stood in some position where they can be fully exposed to the sun. If they can be placed in the position they are to occupy all the better. In the southern parts of the country they will be do very well in the open, but in the more northern districts shelter must be provided; the south side of a hedge will do very well if no better shelter can be given them. They can occupy ground from which an early crop has been taken. The pots should be plunged, placing them as thickly as they will stand in the row, and about 2½ feet between the rows, so that they can be easily trimmed whenever they need it. Each plant will require a stout stake 3 feet high. Strong cords can be run along the rows, with stakes at certain intervals to support them. This is the quickest and easiest method at first, but when the plants have to be lifted inside it is the work of two instead of one. Staking each plant at first is the best, all things considered. The pots can either be plunged, or the surface can be well mulched with manure to prevent evaporation and thus save labour in watering. All the attention needed is to water them occasionally if very dry weather follows, but if the pots are buried or liberally mulched they give but little trouble in this respect. Tie the shoots as they grow to the stakes, and remove all side growths. Confine the plants to one stem each, and the leaves must be reduced if they are becoming crowded. When the stems have attained a height of 2 feet 6 inches, or even 3 feet, they should be pinched, but this should be decided by the manner in which the fruits are setting at the base. If they are setting well no advantage is gained by allowing them to extend above the former height. The point

of the plant should be taken out directly the desired height has been attained. It is a mistake to allow them to grow until a truss of flowers is produced at the height desired, and then cut away the portion above. If the plants are strong, as they should be, and the point is removed directly it can be taken out without injury to the truss of flowers, the plants will devote all their energies to the production of very strong trusses near the top, which are almost certain to set well if the weather is favourable.

When lifted indoors very little harm is done to Tomatoes by the destruction of a few roots that may have extended over the sides of the pots or out at the base. A little fresh manure can be placed on the surface, and if a little heat is employed in the structure, and it is kept moderately close for a few days, they will soon commence fresh root activity and perfect the whole of their fruit. Dwarf-growing varieties, after the style of Large Red, that commence fruiting freely near the base and produce a truss of flowers every second joint, are most suitable for this purpose. By growing late plants in pots and getting them set outside a supply of fruits can be had until the end of January.—MARKETER.

A HOLIDAY EXCURSION.

THE annual excursion of the Walkley Amateur Floral and Horticultural Society, which took place on Wednesday, July 18th, took the form, on this occasion, of a drive by road from Sheffield to the above-named fine Yorkshire residential estates, the parks of which are contiguous to each other, and an inspection, by permission previously obtained, of the beautiful and extensive gardens. Starting at 9 A.M. the first part of the journey—viz., from Sheffield to Rotherham, was performed through the busiest and blackest portion of what is frequently termed "Smoky Sheffield." Having passed through Rotherham (a quiet and sleepy sort of small market town, which in former years appears to have possessed much more importance and business energy than it now does), we emerged into the open country, our road lying along a typical English "country lane," the tall hedges and banks on either side being bright with wild flowers. The pretty village of Wickersley was also passed, where resides the Rev. F. Freeman, whose rectory garden is said to have been the first English home of the now popular summer flowering Chrysanthemum.

A halt was made at the village of Maltby, where the party partook of lunch. Advantage was taken of this by several of the party for a ramble through the village churchyard, which is charmingly kept, and is in all respects one of the most beautiful of its kind in the British Isles.

Proceeding thence along another country lane which leads through a finely wooded district and past Roche Abbey, we arrived at the entrance to Sandbeck Park, owned by the Earl of Scarborough. The Park is extensive and contains some fine timber. A walk of about half a mile across it brings us to the gardens, where, on arrival, we are soon met by the head gardener, Mr. Summers, who showed us through the numerous fruit and plant houses, and kitchen gardens. In the Peach houses we found that the fruit had for the most part been gathered, the little which was left, and the general good condition of the trees, testifying to the fact of its having been of high quality. In the vineries heavy crops of Grapes are maturing, the bunches and berries being medium sized. The shoulders were taken off at the time of thinning to induce uniformity in size and shape of bunches. Several large houses we found to be occupied by fruiting plants of Tomatoes, of which immense quantities are here grown. The varieties most favoured by him are Haekwood Park Prolific and Hathaway's Excelsior; several other varieties being grown, but are not found so free and productive. In a house devoted to Orchids we found a large collection of healthy vigorous pieces recently collected and sent home by his Lordship during his travels in their native homes, and consisting mostly of Cattleyas, Vandas, Lælias, Catacactums, &c., amongst them being several strong pieces of *Lælia anceps alba*.

A new range of Peach houses has recently been erected, in which, in addition to trees trained in the usual manner upon the back wall, others are trained to trellises arranged transversely across the house from the front to the pathway at the back, at about 4 feet apart, each such trellis being what may be termed a double one, composed of two sets of wires with a space of 3 to 4 inches between each set, two trees being planted to each such trellis, back to back. This is certainly economising space to the utmost. As to the ultimate gain in the weight of fruit produced, such has as yet to be proved, the trees being yet too young, but in every respect looking very satisfactory. The kitchen gardens were in excellent order and well cropped. Hardy fruits also were good and abundant. Numerous plants of Raspberry Baumforth's Seedling were bearing a splendid crop of very large fruit, and were much admired. Some very fine fruit were also being gathered of *La Grosse Sucrée* Strawberry. A large and heavy crop of Potato *Mona's Pride* was being dug. They were planted in rows a yard apart, with a row of Brussels Sprouts between each. The latter were larger and finer than any we have previously seen this season.

Leaving Sandbeck Gardens we soon arrived by a pleasant walk of about a mile at the entrance to the beautiful grounds of Firbeck Hall, the seat of the Rev. H. G. Jebb. There a short walk along the carriage drive (which is bordered by a broad belt of well-kept grass lawn and overhung by fine trees of Spanish Chestnut) brings us to the kitchen gardens, where at the entrance we were met by the experienced head

gardener, Mr. W. Egglestone. In every department of these beautiful gardens a high order of culture prevails. In the vegetable and fruit gardens fine crops of excellent quality were the rule, Strawberries (*La Grosse Sucrée*) were exceptionally fine; excellent crops of Peas William I. and Supreme were being gathered, the latter variety especially being in fine condition. Along the south side of this garden runs the vineries, consisting of three large and lofty lean-to succession houses. In the earliest house was a heavy crop of moderate sized bunches and berries, just finished ripening. And such finish! Indeed, we do not remember having seen a house of Black Hamburgs (of which variety these principally consisted) so densely and regularly covered throughout with a deep blue bloom as these were. I need hardly state that the foliage was very fine; such finish would have been impossible had it been otherwise. In the late house was also a heavy crop of larger bunches just thinned, the varieties being principally Lady Downe's, Alicante, and Alnwick Seedling. A large number of bunches of the first-named were especially fine, being long, well shaped, and perfectly furnished with well set even-sized berries. Should these take on a finish equal to the Black Hamburgs in the early house they would prove formidable on the exhibition tables at our late autumn fruit shows. On an outer open wall also facing south we notice a very fine crop of Peaches and Nectarines.

Upon the lawns are numerous Conifers in splendid health and well furnished, ranging in height from 30 to 50 feet, amongst them being *Cedrus atlantica* (many fine trees), *C. Deodara*, *Cryptomeria Lobbi*, *Cupressus Lawsoni*, *Wellingtonia gigantea*, *Thuja borealis*, &c. The mansion is a many-gabled Gothic structure, a portion of it being of ancient date, but all in excellent repair. The west front commands a beautiful view along the finely timbered park, bounded on each side by woods, with a fine piece of ornamental water spanned by a handsome bridge in the foreground.

Perhaps the most beautiful feature of Firbeck Gardens remains yet to be described, and this is the terraces and flower gardens on the south front, in which Nature and Art appear to be so exquisitely blended as to form a picture worthy the pencil of a Turner. Mr. Egglestone is evidently a true artist, as although high colours are largely used in the composition of his picture, they are so well balanced and toned down by the surroundings that the most captious critic could scarcely fail of being pleased and satisfied. Carpet bedding is extensively and well done, appearing especially suited to the position, the *Alternantheras* and other tender plants being quite at home in this warm and perfectly sheltered glen. Amongst the varieties of *Alternantheras* used by far the best and most effective is an unnamed seedling raised at Firbeck by Mr. Egglestone, which is superior in brightness of colour to *A. amoena*, with the advantage of a vigorous habit of growth. The finest feature of the bedding was the numerous beds of Tuberous Begonias. We have never before seen these so thoroughly at home and so satisfactory in every way as bedding plants as we saw them at Firbeck. The plants are all very dwarf and stout, with large ornamental foliage, flowering abundantly, the flowers being all of the largest size and of the brightest colours.

Numerous large plants of *Yucca gloriosa* between the flower beds were throwing up strong flower spikes. A very striking feature on the upper terrace, which attracted the attention of the whole party, was what might very well be termed a trophy of succulents in the shape of an immense garden vase, the whole of which from ground line to apex was ingeniously covered, the lower half with the Californian House Leek, the upper half with *Echeveria secunda* glauca, the whole surmounted by a good specimen Aloe. The conservatory overlooking this terrace was well furnished with foliage and flowering plants and Ferns. A good addition to the general effect, as seen from the windows of this conservatory, is the lower terrace wall, which is covered and hidden by a coping of English Yew, 2 to 3 feet in breadth, kept closely trimmed, and quite flat about 1 foot above the ground line, and from which spring at regular intervals specimen oval-shaped bushes, almost perfect in symmetry, of the Golden English Yew.

After a substantial repast, provided at the village inn at Firbeck, and a visit to the beautiful village church, recently enlarged and thoroughly restored by Mr. Jebb at his own cost, the party returned to "black" and "smoky" Sheffield thoroughly satisfied with what they had seen and so greatly enjoyed.—W. K. W.

CABBAGES FOR SPRING.

I HAVE read with interest the chapter by "A Kitchen Gardener" on the above, and must say of the varieties I have grown I like Ellam's Early the best. I have not tried Webb's Emperor, but may do so another year. Last autumn we planted three varieties—viz., Ellam's Early, Early York, and Little Pixie. Ellam's Early was ready first, long before the others; in fact, very few of Early York have been cut, they have nearly all "bolted." No more of that variety for me. Little Pixie has not "bolted," but it has not hearted well, and is far behind Ellam's Early. I remember in my apprentice days, fourteen or fifteen years ago, it was thought a great deal of, and certainly was a good little Cabbage in those days.

I must take exception to "A Kitchen Gardener" about the time for sowing. He says, on page 90, August 2nd, "It will never answer to sow Cabbage seed early in July." Now that is just the date that does answer in this district. Ours last year was sown the third week in July, and was found to be too late; and if we had not obtained some plants which

had been reared from seed sown in the first week of July, we should have been badly off for Cabbages the last two or three months.

We sowed the seed this year in the first week of July, and they are making so little progress that I am afraid they will be late for planting. I do not like to see them large in November, but I like them to have a good hold of the ground by the beginning of October, all growth being stopped by then in this district. We plant about the last week in August on ground from which early Potatoes have been lifted without any manure being dug in; 18 inches between the rows, and 1 foot apart.—G. HILTON, *Lancashire*.

BARLERIAS.

THIS is a large genus containing many very fine species which unfortunately have not been introduced in a living state. They are distributed over the tropical portions of both hemispheres, nearly fifty species being known as African, whilst the peninsula of Hindostan is very rich in members of this genus. They thrive best in good light soil, and as their growth is rapid we certainly prefer young plants every year.

B. Gibsoni (fig. 14).—A neat branching shrub, attaining a height of several feet; but handsome well-furnished plants some 2 or more feet

FIG. 14.—BARLERIA GIBSONI

high may be grown from cuttings in a single season; and as these not only bloom freer than old plants, but produce the finest flowers, there is no advantage in keeping the old ones. The leaves are upwards of 3 inches long, ovate-lanceolate and acuminate, deep green above, glaucous below, and somewhat coriaceous in texture. Flowers funnel shaped, produced in terminal and axillary spikes near the ends of the branches; lobes spreading, colour pale purple, the two upper lobes having a dark purple blotch in the centre. It flowers in midwinter. Native of Central India.

B. Mackenii.—A species closely allied to the preceding, but a native of Africa and not India, having been introduced from Natal, a portion of the world to which the public attention has been so earnestly directed during the past two months. It is a very ornamental plant, attaining the proportions of a small shrub. Stem slightly but very obtusely four-angled. Leaves somewhat ovate and subacute, recurved, about 3 inches long and nearly an inch broad; colour deep green, and clothed on the upper surface with small close hairs, as also is the stem. Flowers not so freely produced as in the preceding species, but very handsome,

funnel shaped; the limb flat, some 2 inches or more in diameter; colour rich purple, with an intense deep purple blotch on each lobe. It flowers during early spring.—T.

THE HEAVIEST STRAWBERRIES.

If "Saxoring" would make a search in the back numbers of the Journal from 1862 to 1866 he will see an account of heavy Strawberries either by "D., Deal," "Upwards and Onwards," or "Wiltshire Rector," I cannot remember which. They had several articles on growing Strawberries which contained much valuable information respecting weights. I do not remember the weights of Dr. Hogg likened to "ladies' bags," but Cockscombs weighed about 4 ozs. each, and these went to regale the bowlers or cricket players. I have had individual Dr. Hoggs weighing 2½ ozs., and Cockscombs 4 ozs. and one grain each. These Strawberries were sent to the editors of different papers, and I remember the editors had taken the pains to weigh them and recorded their weights. Cockscombs were so large that they would not enter the mouth of a common sized tumbler; but with me it was difficult to grow, and requires great care in its cultivation to ensure healthy and strong runners.

I have picked from a bed of Dr. Livingstone basketfuls of equal sized Strawberries, eight and ten to the pound; these were the first picked however, but when this Strawberry is well grown there are few small ones. Its lightish red colour makes it the favourite of market gardeners, and its robust nature and prolificness makes it the favourite Strawberry of all who try it. No Strawberry will grow under trees so well as it does. It is not so large as Cockscomb nor so handsome as Dr. Hogg or Sir Joseph Paxton and a host of others, but it will bear a crop where some of these as well as many of the finer new varieties fail, and from what I have seen would be equal if not superior to President, which it resembles. Dr. Hogg reported in the Journal on a sample of this Strawberry I sent to him as excellent, and Mr. Barron gave similar testimony on a basketful sent, but too late to put before the Fruit Committee of the Royal Horticultural Society some twelve or fifteen years ago. From a small plantation of well grown Dr. Livingstone planted upon rich, new, or virgin unmanured soil, I pulled 4 lbs. from each yearling plant. I always consider that it is waste of time and ground to allow Strawberries to grow longer than two years, as they exhaust the soil much, and it takes longer to have it in a fit condition for Strawberries again than when grown as annuals and then dug down. When this system is properly carried out better and more fruits are obtained, while a new plantation may be made three years after with safety, whereas six or seven years is early enough to plant after a four or five-years crop.

Many do not pay the attention to Strawberries nor the varieties necessary to insure success, and it is seldom we can depend on getting a Strawberry true to name. Vicomtesse Hericart de Thury is grown under a dozen names, or perhaps more, and is wrongly I think also named Garibaldi. The almost continued drenching rains we have had for the past two weeks defies us to test by flavour, but I have just been comparing a few growing plants of both, and while Garibaldi has broader leaves and a different hue than Vicomtesse, they are also reflexed, while those of Vicomtesse are not. When I have a difficulty about two Strawberries, I generally decide by the flavour of their foliage, which is sometimes as distinct as the fruit itself.—W. T.

MYRTLES IN THE OPEN AIR.

MYRTLES are favourite plants. Their neat habit of growth and pretty green leaves are very pleasing, and their agreeable odour renders them still more acceptable. They are frequently grown as greenhouse plants, and I have noticed good specimens in windows, but plants in the open air are not often seen. Indeed, their culture in the open air is rarely attempted, and this is to be regretted, as fine Myrtles in the open air are always admired and attractive. In fact, they are generally looked on as curiosities; but they are more than this, and come under the heading of choice evergreens. I would not recommend Myrtles being planted in very exposed places, but they would succeed in many districts in sheltered nooks and against walls. I know many instances of their growing most luxuriantly against south walls. Here our largest Myrtle is planted against the south side of Margam Church. It is 18 feet high, 12 feet across, and projects a long way out from the wall. Some winters it has been injured by frost, but we never protect it; not even from 18° of frost, and it soon recovers in the summer. In August and September it becomes a mass of white blossom, and is a fit associate of Orange flowers. Should fear be entertained of their being injured by frost it is easy to mat them during severe weather, and the anticipation of their being injured by cold or bad weather would never deter me from planting them.

When young, Myrtles in pots are generally green and ornamental, but older plants are apt to become scraggy, and it is plants of this stamp that would soon be benefited by placing in the open. The present is as good a time as any to plant them out, as they would not receive any check now, and they would be hardened and established before the winter. They will succeed in almost any soil, but it is important that it be well drained, as wet and stagnant soil at the roots in winter proves far more injurious to them than a cold atmosphere.—J. M.

SOME RELIABLE VEGETABLES, WITH NOTES ON CULTURE.

FROM this time forward the shows will include vegetables; and gardeners and amateurs will be forming their opinions as to those they will grow and those they will discard another season. There is some wisdom in the old couplet—

"Be not the first by whom the new is tried,
Nor yet the last to lay the old aside."

I should be more inclined to agree with the latter proposition than the former, as I am a firm believer in progress; but from my own experience, and from constantly moving about among gardens and gardeners, and occasionally judging at shows, I am satisfied there are some very old vegetables—*e.g.*, the Ash-leaf Kidney Potato—Myatt's, Rivers', or Veitch's; Snow's Broccoli, Walcheren Cauliflower, &c., that time writes no wrinkle on their deserved popularity. The difficulty seems to be to get the real "Simon Pure." Permit me to notice a few varieties, briefly of each, to which others can add.

POTATOES.—Early and general crop. For the first time I have on trial this season a real rival for the old Ash-leaf Kidney in Carter's Earliest of All. Though for thirty years raising seedlings and trying different varieties, I have hitherto steadily maintained my preference for the old Ash-leaf for first crop. The produce is limited but the quality is unsurpassable. Earliest of All has the same good qualities, and more than twice the produce. Another very promising early Potato is Delight. For general crop, either garden or farm, many still grow the Champion for midseason, and Scottish Queen or Magnum Bonum for to wind up the late with. I prefer The Hero or Laxton's No. 10 to either. As this season is exactly the reverse (very wet) to last, which was very dry, different results must necessarily be obtained. I regret to say the disease has already become general among early varieties here.

CAULIFLOWER.—Those who have their early Potatoes removed and have strong plants to put in at once, may expect good sized heads before frost sets in. The quickest to turn in, and of superior tenderness, is Extra Early Defiance. Dwarfier and hardier is Mammoth, while Walcheren will not mind a few degrees of frost. Veitch's Autumn Giant is indispensable. Ground can hardly be too rich for Cauliflowers, but I never manure after Potatoes in transplanting. If I think it necessary I give some liquid manure, and this would be necessary for those who exhibit, and where size was a consideration. For private use neither extra size, coarseness, nor too much manure should be encouraged. The latter, besides affecting the quality, diminishes the power of resisting cold, and the keeping properties as well.

BROCCOLI.—Those who have sufficient Cauliflowers planted already, as will in many cases be likely, will do well to grow Broccoli; then Snow's White Winter (true), to be followed by Mammoth Spring White and Cattell's Eclipse. Again, I say, if the ground has been already manured, and is fairly rich, neither manure nor dig—plant with a crowbar—they will stand the winter better in the absence of both.

CABBAGES.—I still prefer Early Heartwell, and those gardening friends I recommended it to years since take the same view. A larger variety of the York shape of head is Mammoth Beef-heart. In this locality there is a variety of Early York called "Wellington" that I am not aware is elsewhere known to fame; it matures early, is tender and juicy, and has little waste in outside leaves. They save their own seed, and thus maintain the purity of the strain. Flat Dutch is now seldom grown in gardens, occupying ground too long, and only fit for cattle—too coarse.

CELERY.—Except for the last succession it is now too late to plant Celery, and even then the plants must be large and well established. In spring I have often seen a preference given to the Celery last planted as being "younger" and more tender than the great specimens thick as your arm, and 3 feet long. These last are only fit for the kitchen, and it is doubtful if judges should not give a preference to the former, except the schedule otherwise specifies. Hollow Celery is of course inadmissible. I may here mention I have found a sprinkling of soot an antidote to the ravages of the Celery fly. Do all your readers know that Celery is one of the best anti-rheumatic agents, and for that purpose best used uncooked? Solid Ivory White is one of the best in quality, but not so hardy as Standard Red. Henderson's White Plume is very handsome, but requires litter thrown over the lines in winter, and even thus it rapidly decays.

PARSNIPS.—The best quality variety I know is Maltese; but if properly cooked, mashed, and served with gravy, Hollow Crown has a preference where quantity is a consideration. The constituent analysis of this vegetable places it higher than its popularity will ever reach.

BEANS AND PEAS.—For the former and show purposes the greatest size is attained by Leviathan. I saw them 20 inches long at Manchester.

Show, and the same at South Kensington in 1887. For family table use, however, I prefer Green Windsor. Peas require more space to notice than you can spare, so I shall merely mention half a dozen my gardening friends give a preference to, in the order of succession—Lightning, Anticipation, Daniel O'Rourke, Stratagem, Telephone, and Pride of the Market, with Ne Plus Ultra as a substitute for any other.

GARDEN TURNIPS.—I find I have exhausted the permitted space and without including many vegetables that most gardens require. I am among the majority in preferring golden or yellow-fleshed varieties. They are firm, sweet, and of better flavour. None better than Golden Rose. If white is desired take Jersey Lily; if black, Chirk Castle is still unique.—W. J. MURPHY, *Clonmel*.

INCIDENTS OF THE JOURNEY TO THE WIRRAL SHOW.

THERE were seven on Tuesday night in one carriage on the Irish mail from London; four were warriors of the Rose, wending their weary way to Wirral Show. Consequently, some of us had to court the god of sleep sitting bolt upright. The carriages were beautifully cushioned, though the oscillation was considerably more than on the two other northern lines. One of our party was one of the two indefatigable ladies without whom no great Rose Show would be complete. At Crewe some of the western exhibitors joined our contingent, and by 2.30 we reached Chester. Here we changed to the Birkenhead train. The guard, on being asked if our van of Rose boxes would be put on all right, replied that he knew nothing whatever about it, but would see what could be done. Most of our party had already settled themselves into various corners of the carriage; I was waiting news from the guard. Suddenly looking round, I saw the train—without any apparent reason, except that it seemed tired of waiting—making headway out of the station. After a sharp run I landed into the guard's van, among the mail-bags and parcels. No guard was there, though. Evidently, I thought, we are only shunting. On and on we went, stopping at last within a ten-minute's run of Birkenhead. Presently the door opened and a light appeared. "Good morning," said I. "Good morning, sir. Where's the guard?" "I am the guard; what do you want?" "But where's the other guard?" "Can't say; all I know is I'm the only guard on this end of the train." "Well, I'm a passenger guard sent down to look after you." I told him all I knew, and he seemed to believe that, as the mail-bags were quite safe, I had not pitched the man out of the train. "This was the rummest go he'd known for a long time."

Imagine the dismay of our exhibitors when they heard that all their Roses were at Chester, and the next train would not arrive till nearly nine o'clock in the morning. A telegram soon quieted their fears, and in due time the boxes and guard arrived by a special train. By this time it was nearly four o'clock, and some of our party, as no waiting-room or other accommodation was provided, went across to the Homeside Hotel to turn in for awhile. The enthusiastic jovial Gloucestershire parson, the Herefordshire ex-champion amateur, the professional holder of the challenge trophy, and the Wiltshire nurseryman exhibitor grouped themselves round the door of the hotel, while all due efforts were made to arouse attention from the inside. It seemed surprising how much wit and wisdom could be displayed in spite of the early hour, the pelting rain, and the sodden thoroughfares. For some time the ominous growl of a dog inside was the only response to our appeal to the bell. Presently, just as we were about to move on, a sound was heard, and an unwashed, half-awakened, half-arrayed child of man, with just the amount of clothes on that never leaves him, peered his sleepy eyes round the door. He was greeted with a volley of questions. After a vigorous application of first one, then both, fists to each eye, to assure himself that we really had been indulging in a night of revel, the effect of which gave us the unsteady appearance his dull brain imagined, he gazed as steadfastly as his sleepy condition would permit at our friend of the cloth, and merely said, "You ought to know different!" and vanished, locking the door before our splitting sides would allow us to interfere. It was a glorious joke, not to be lost for anything. Evidently there was every excuse for the rest of us, but the parson—he ought to "know different." There was nothing to be done but to return to the station, and for three dreary hours to kick our heels out.

May I venture to suggest that in future the Wirral Society make some preparations for the exhibitors whom they know will turn up by the 3 A.M. train? otherwise they will hardly get the competition in future they were fortunate enough in having this year.—W. H. W.

ROSE SPORT.

WE received on Saturday last, too late to send on to you, a curious sport of Madame Marie Finger Rose. The Briar from which the blooms were cut was budded last year. A fortnight ago the plant developed its first bloom, which was quite dark in colour. The two blooms we had sent us were both on the same shoot as the first bloom,

but they varied considerably. One bloom was easy to recognise as a true Madame Marie Finger, with its fleshy pink colour, shaded darker in the centre, while the other was quite dark in comparison, about the same shade as Duc de Rohan. They had both developed simultaneously on the day before they reached us. On one shoot, therefore, we had at the same time two apparently quite distinct varieties of Roses.—KEYNES, WILLIAMS AND CO.

ROSE HER MAJESTY.

WHATEVER different opinions there may still be as to the merits of this Rose, it will, I think, be allowed to be the most remarkable new Rose of this decade. We all remember the sensation caused by the numbers and size of the blooms exhibited in the year when it gained the gold medal, its strange alleged parentage, the disappointment experienced when it failed to appear in the market, and altogether disappeared from view; the rumours as to the price required being beyond English nurserymen, and as to buds having been stolen; the report that Brother Jonathan's dollars had at last secured it at an extraordinary figure—all these circumstances, we remember, caused a considerable run upon Her Majesty when at last it appeared in the English trade, and many invested largely.

About this time, too, some expressed their doubts as to whether it was really a good Rose, alleging that it was coarse and wanting in regularity of shape. I was one of these, and a little chaff passed between me and my friend "F. H. G." in the *Journal* on the subject. He seemed to think it would generally be the "best H.P.," and I said it would never get the medal, being deficient in shape. All right! I am going to apologise presently. Well, we all remember what a comical feeling of disappointment ensued in 1886, when it almost universally refused to flower, and hardly anybody had a single bloom to show. We were obliged to postpone our criticisms for one year more, and in 1887 a good many blooms were shown. The general feeling with those who only saw the Rose as exhibited was probably that the adverse criticisms were upheld. At the principal exhibitions the majority of the blooms were like those shown for the gold medal—*i.e.*, expanded, and deficient in shape. Here and there, however, one or two might be detected which had been cut smaller, of better colour, and of far better form. I had two or three blooms, and by cutting them young I showed them of good shape, and, but for a caterpillar hole in one petal, should myself have won the prize for best H.P. with one of them at a local Show. It may possibly be remembered that I did express a more favourable opinion, accordingly, of Her Majesty, in the *Journal* last autumn; and I should now be ready to apologise to "F. H. G." and to Her Majesty herself for aught I have said against her, even if Mr. Lindsell had not actually won the medal for best H.P. with it at the N.R.S. Show at Darlington. (I have got seriously "mixed" with my pronouns, but, in proof of the sincerity of my apology, will give Her Majesty the benefit of her sex in future.) It seems to me that Her Majesty was libelled by Mr. Bennett himself when first shown. It is a wonderful quality in this Rose, especially considering "her" parentage, that she remains full, shows no eye, and is still presentable, even in the expanded state; but she is then quite past her best, for in a younger state she may be shown of beautiful form and colour, and will, I have no doubt, gain many more medals.

But, though the young bloom is sometimes of the sensational character which has attended Her Majesty throughout her existence, I am afraid that very little praise can be given to her as a plant. I forget how high one of the plants shown by Mr. Bennett in a pot was—certainly well over my head—the robustness of the growth and the size of the thorns seemed as sensational as the blooms; but I do remember how mean was the appearance and growth of some rows of maidens at Mr. B. Cant's a few days ago. Fully half of my own plants have not grown more than 3 or 4 inches, and I have had a proportion of about one bloom to seven plants. It seems that Her Majesty is not graciously pleased to approve of the weather which we have had to call summer this year; and, however much we may be disappointed, we must allow that it shows her sense. However, although the plant cannot be called a free grower or a free flowerer, I have no doubt that the blooms will be indispensable to exhibitors for many years to come.—W. R. RAILLEN.

A WEEK'S WANDERINGS.

BLACK PIGS AND WHITE ELEPHANTS.

IT so happened when I was at Swanmore that Mr. Molyneux, who is the Honorary Secretary of the Bishops Waltham Horticultural Society, had arranged to go on a tour of judging a number of cottagers' gardens. As I learned a carriage was engaged for a long drive, and there was room in it for a small man, I stole a day for what I thought would be an easy method of exploring the wilds of Hampshire. I had heard of "Hampshire hogs," and suggesting that we might see some, was met with the reply of "Yes, but they will be all black 'uns," and I was further enjoined to observe that wherever we found a particularly well cropped garden and vegetables of unusual excellence to look for the pigs, as there would sure to be some on the premises and they would as surely be black. And so it was. In nine cases out of ten the owners of the most productive gardens were also owners of two or three black pigs. One assisted the other clearly, and both contributed to support the families of the sons of toil in the district. We saw many good pigs and good gardens that day, and thought the peasantry of the villages were not uncared for, and we could not fail to contrast the advantages they enjoyed in comparison with their fellows in the pent up and

stifling lodgings in London to which so many had come, tempted by higher wages to "better themselves," even at the risk, often a deplorable reality, of being half of their time out of employment. It is to the advantage of all to keep the workers on the land for developing its resources, and if this cannot be done in the best manner in large tracts it can be in smaller plots, and in the parishes visited the clergy were taking an active interest in encouraging garden culture and providing plots of land for their humbler neighbours.

It was very noticeable that the offering of prizes for the best kept and cropped gardens was exerting a wholesome influence in stimulating effort. The gardens in competition were remarkably neat and closely cropped, and very few of the others were wholly neglected, as only the most careless of persons are contented to remain very far behind their neighbours in the condition of their home surroundings. Field allotments were also found splendidly cultivated, and it was pleasing to see that the rector of the parish (Dorley) took as much pride in them as did the tillers themselves. But what about the Elephants? It is scarcely necessary to say that these are Potatoes.

It is surprising how far and how widely the White Elephant Potato has spread. It is evidently a great favourite with cottagers. In northern and southern gardens we find its culture extending, and in the Hampshire plots it preponderated over all other varieties. Large luxuriant breadths were seen everywhere, and could not be mistaken, covered as they were with great bunches of white flowers, rising above the spreading walnut-like leaves, and producing in the mass quite an imposing effect. But do all the growers know that when the blossoms set and seed berries swell to maturity, that they will check the growth of tubers if the so-called "apples" are not removed? It will "pay" any cultivator to cut off the trusses when the flowers fade, and the sooner it is done the better the results will be. The ripening of such a large crop of seed takes as much plant nutriment out of the ground as the tubers do, while the seed is of no value, and practically represents waste. Clergymen who read these notes, as many will, if they have time and patience to do so, may do the peasantry of their parishes a good turn—at least those who have a heavy crop of seed on their White Elephant Potatoes—by advising them to take off the trusses at once.

We now pass to another phase in these wanderings, and leave parsons, peasants, pigs, and Elephants to help each other in the economy of village life.

TWELVE HOURS OF JUDGING.

The day that was entered on as a day of ease, lolling in a carriage, turned out a day of hard labour—pleasant labour, no doubt, yet exhausting. Does this raise a smile? It is easy to imagine it may do so. Riding about from garden to garden judging hard work, pooh! But has anyone who doubts tried it from half-past eight in the morning till beyond that time at night, rushing from parish to parish over forty miles of roads, pacing up and down forty-nine gardens, examining critically every crop, estimating its value, and recording it, finding in some gardens thirty varieties of vegetable and bush fruits to appraise? If he has done this thoroughly, shirking nothing, he will think he has done a good day's work if nobody else does, and be ready for a little rest at the end of it. It was most gratifying to see the admirable condition of many of these gardens, the careful cropping, admirable culture, the trimness, cleanness, and evident pride taken in them. The winners of the prizes were worthy of them, and it is a pity there were not a few more to award.

The manner in which the judging was done may perhaps be suggestive to others interested in work of this nature. It is not advanced as by any means a perfect system, and if improvements can be proposed so much the better. It may be stated that, for the purpose of putting all the competitors on a level, the day of inspection was kept secret till the morning previous, on which day each competitor received a post-card, so that one evening only was allowed for trimming up. This had been taken advantage of, as might be seen by the freshly clipped hedges and general cleanliness of the paths and beds. The principle on which the judging was done differed somewhat from that which is generally followed. It is customary to give either three or six points as the standard of merit of all vegetables, and then as they fall from that standard to enter the figures accordingly. A standard of three marks is quite inadequate for working from, as the gradations in merit cannot be expressed with sufficient exactitude. A standard of six is far better; but as all vegetables when grown in the best manner are not of equal service to cottagers, it is surely right to give more marks to the most useful kinds than to others that are not essential in cottage homes; otherwise the man having the greatest number of varieties, whether of service or not, would, even if some were not well grown, score higher than another who grew a less number of the most serviceable and grew them all well. For instance, good Potatoes, Peas, and Cabbages are more worthy of honour in a cottage garden than Radishes, Beet, and Mustard and Cress. It was therefore determined to make eight the standard of merit for Potatoes, Cabbages, Peas, Broad Beans, Scarlet Runners, Onions, Turnips, Carrots, Parsnips, and Winter Greens, these including Broccoli, Brussels Sprouts, Savoys, and Kales, the same number of points being the maximum for order. For everything else, including bush fruits, six points represented the standard of merit. The plan worked very well, but is open to improvement, if in no other way than making ten the maximum both for Potatoes and order, owing to their commanding importance, and probably other modifications might be made with advantage. The cultivation of flowers was encouraged by ranking them with the order of the vegetables, with eight points as a maximum, a few flowers well tended making the village

homes more bright and cheerful, though the primary object in country gardens is utility. The names of the prizewinners are not given, except in two cases, where the contest was very close for the champion prize for the best cropped and kept garden in the whole district. Both the gardens are in the Swanmore parish, and the manner in which the prize was won by Mr. C. Baker and lost by Mr. E. Ainsley is shown in the following figures, there being a difference of two points only between the competitors. The figures will also make clear the method of judging.

CHAMPION GARDEN PRIZE.

The figures in the first column represent the points won by Mr. Baker; in the second those won by Mr. Ainsley.

Varieties.	Points of Merit.	
	Baker.	Ainsley.
Potatoes	8	8
Cabbages	2	6
Peas	10	7
Broad Beans	4	3
Scarlet Runners	7	1
Onions, spring and autumn	12	10
Turnips	5	9
Carrots	2	7
Parsnips	4	5
Winter Greens and Broccoli	8	4
Caulliflowers	6	4
Vegetable Marrows	4	4
Dwarf French Beans	1	1
Red Cabbage	5	4
Celery	6	5
Rhubarb	1	4
Cucumbers	1	2
Parsley	2	1
Mint	0	1
Lettuce	2	4
Radishes	1	2
Mustard and Cress	2	0
Beet	1	1
Tomatoes	3	2
Spinach	1	0
Black Currants	4	2
Red Currants	1	3
Gooseberries	3	4
Raspberries	0	3
Flowers	6	7
Order	5	5
Shallots	2	5
Leeks	2	1
	121	119

It will be seen where the competitors were strong and weak respectively. It should be explained that two extra points were given for Peas in the first column. They were so extraordinarily fine that the addition was necessary in the interests of justice. Spring and winter Onions are added together in the columns; in the judging Mr. Baker had seven points for the former and five for the latter, Mr. Ainsley having six and four respectively. Both men deserved medals for the excellence of their work.

After spending a couple of days with Mr. Molyneux, pleasantly, and it is hoped not unprofitably, I thought I would go on a little exploring expedition to the Isle of Wight, and see if I could find Mr. C. Orchard. He was discovered in a delightfully situated house overlooking the Bay of Sandown. Another discovery was made—a *ci-devant* gardener, a gentleman who has wielded the spade and worked as hard as any reader of these notes, but now an alderman and magistrate, who drives his carriage and pair on land and runs his steam yacht on the sea, who will one day be an M.P. if he can obtain votes enough; but he is a true gardener still, in full sympathy with the craft, and gives its accredited representatives a genuine grip and greeting. Mr. Orchard is his friend and helper in a great work; he is the master of a harbour and appears to be the controller of a railway, over which he gave me a free pass during my sojourn in the Isle—unfortunately too short, the rain driving me home, but only, I hope, to go again another day. But who is this ex-gardener? It must suffice to say at present that he has worked his way upwards by his ability, high character, and indomitable perseverance. I will hope to tell who he is and show what he is like another day.—A WANDERER.

NOTES ON FLORISTS' FLOWERS:

AURICULAS.—In one sense the cold weather we have experienced in what is regarded as the hottest month of the year (July) has been favourable for a plant which, like the Auricula, dislikes heat. My frames, quietly ensconced at the back of a hedge and facing north, have been delightfully cool, and the plants have evidently rejoiced in it; but there is another side to the question. Are not the plants just growing a little too well, and may we not expect a considerable amount of autumn blooming? That at any rate was Mr. Ben Simonite's opinion when I was talking the matter over with him at the Carnation Show, and I can hope that his anticipations may not be realised, but he is too intelligent an observer to make one think lightly of any opinion he puts forward. Of course greater care will be necessary in the matter of watering during the cold and dripping weather that we have experienced for so long. The plants must not be allowed to flag, but they should not be so liberally supplied with water as in ordinary seasons. I reported mine during June, somewhat later than usual, and found in so

doing a large quantity of woolly aphids on some of the plants. This I carefully removed, and washed the roots where virulent, but I am less distrustful of it than I used to be. I do not think plants ought to have it, but I think unless it attacks the collar of the plant it does not do a great deal of harm. I have noticed that several old plants have gone off in a species of black rot, the cause of which I am unable to discover. May it be that the *Primulæ* are not very long lived? and that as we find with many of the species it is best to keep them up by occasional sowings, so it may be that these old plants are only following the ordinary course of nature and dying of old age; if so, not only the advantage but the necessity of rearing a good progeny of offsets is evident.

CARNATIONS AND PICOTEEES.—The season has had a wonderful effect on these plants. This was fully evidenced by the Show held at the Drill Hall on July 24th, when so very few flowers were staged, and some large exhibitors were utterly unable to put in an appearance. The long cold and wet time in the latter part of June and the first three weeks of July (indeed, not much better since) so retarded the bloom. It always used to be thought that the 20th July was about the right time, and in some seasons it was quite late enough, but I had neither in the borders or in pots a single flower open at that time; but the same weather which militated against the bloom was favourable to the growth of the plants, and in most cases luxuriant, but perhaps a little too sappy, foliage is the result. My small collection is now under glass, not in a house, but simply a glass roof, open at all sides. Here I hope that the "grass" will ripen somewhat before layering begins, otherwise there is a likelihood of the layers damping. Some of the foliage looks what John Ball calls "gouty," but it is generally very fine. The material for layering should now be ready; it ought to be light with a good admixture of sand or grit, so that the young roots may easily push out their roots. The best pegs are those made of bracken. Few care to layer the plants while they are in bloom, but no time should be lost after that, as they will be late this year, and it will be well to get everything ready for the work. Those who grow in pots have a great advantage, as the operation can be performed under cover, and the plants brought up to a comfortable height. It is backbreaking work to layer them on a bed, although many are obliged to do so.

CHRYSANTHEMUMS.—The wet time has been favourable to these, and they have grown luxuriantly, so much so that it will be necessary to be very careful about staking them, as they stand a good chance of being snapped off. So many directions were given last week in the *Journal* that I need not dwell on this flower. I have found earwigs a great nuisance, and I am afraid many of the shoots are seriously injured by their depredations. They seem to be uncommonly abundant this season, but as yet, strange to say, they have not troubled my Carnations and Picotees much.

GLADIOLUS.—Very very backward is what we must say about these. On the 26th July I have always been able to cut a spike of Shakespeare; if I cut one three weeks hence it is as much as I shall do. My plants look uncommonly strong, although the foliage is somewhat yellow, but this I attribute to the great quantity of rain; it is not the yellow which denotes disease, for I believe this still to be the cause of our losses. There are some who still write and talk about degeneration, but this is all moonshine. I met an American grower lately, when I had a long talk about our favourite flower; I asked him, Did he lose any? "Oh, yes, of course I do," was his reply, "but perhaps not so many as you do in England, as our autumns are more favourable." But still they have the disease. When good folk shut their eyes and ears and ignore the plain statements of scientific observers, what can we say? I very much fear that the flowers will be late for the exhibition at the Crystal Palace, and that the northern exhibitors will be handicapped. As soon as the spikes begin to show themselves staking should be proceeded with if it is desired to keep them in good condition. I had thought of mulching my beds with cocoa-nut fibre refuse, but this wet time effectually prevents all necessity for that.

PANSIES.—The cool and wet weather has just suited these. My small collection is grown in pots, and last year when I took them out of their pots and planted them out they suffered terribly from mildew. This year it has not appeared, and the plants look most vigorous and healthy, and keep blooming away very well. I am thus hopeful that they will now get through the season (summer one can hardly call it) without many losses, it being more like what they are accustomed to in Scotland, where they flourish so well. Of course, I mean *fancies*, for I confine myself almost entirely to these; they are so much more vigorous than the show sorts, and there is so much more beauty in them.

RANUNCULUS.—It has been a somewhat difficult matter to get these up in proper condition, and yet one dare not leave them in the ground after they are fit for taking up, for if once they begin to shoot out afresh the growth is utterly useless. And at the same time it does not do to take them up too soon, as then they shrivel up and lose vigour, so that in a wet season such as we are passing through they require to be very carefully watched. I have never been able to dry mine as the Dutch growers dry theirs; they come over in such plump condition, whereas mine have been more or less shrivelled. When they are thoroughly dried they should be put away in some cool and airy place, but free from frost.

ROSES.—There is a very strong growth in Roses, and those who wish to encourage them to make fresh wood will not hesitate to apply liquid manure, and the heavy rains we are now experiencing will speedily wash it down to the roots. All dead flowers should be carefully taken away, as they spoil the appearance of the beds. The dark red Roses

rejoice in the cool weather, and open freely, but many of the light-coloured varieties are just simply a ball of soddened leaves. It is very difficult, too, to keep the beds free from weeds; hoeing is of no use, and it is only by hand-weeding that they can be kept clean. When the plants have sent up long shoots, say 5 or 6 feet, it is better to stake them, as they are very brittle, and a high wind is apt to snap them across. Now is the time for budding, and a good time it must be; carefully, when you have the opportunity, select the buds from a blooming shoot.

TULIPS.—The bulbs of these are very strong, and there is nothing to say about them except that they should be stored away in a dry place either in boxes or bags.—D., *Deal*.

THE WEATHER.

IN connection with the extraordinary weather experienced during the last few weeks, the following meteorological particulars supplied by Mr. Simmons, the aeronaut, will no doubt be of general interest:—"In the balloon 'Rockwood' on Wednesday evening, August 1st, my experience was not in all respects a desirable one. I left the Anglo-Danish Exhibition at 6.15 P.M.; at 6.20 I was between one thick cloud stratum at an altitude of 6000 feet, and another at an altitude of about 10,000 feet. I had some suspicion that there was a current from the west. I looked in a direction which I conjectured to be east, and from that quarter came swooping on a great mountain of purple fire. The rumbling I could scarcely distinguish from the buzz of London, and I felt assured that as long as the sound was so faint there was a great distance between me and the storm; but at seven o'clock it was nearer to me. I tried then to get on a lateral level with it, but to this end I must have parted with my precious store of ballast, and, finding the thunderstorm keeping up a stern chase, I peered below the cloud stratum to see if I had a chance to descend. I found myself in rather too close proximity to a town or village. I have no idea what place it was, but I was bound to escape it by soaring again, and when I did so I estimated that the thunderstorm was about sixty miles behind me (to the N.E.). Then at 7.15 I had another suspicion that I was being borne upon a western current, for I could hear no sound but that like the surf upon a shore, and I again came down. When I did so I was convinced that the sound of the water must have been a mill race or a weir. I landed safely at Guildford, and the storm by which I had been so hotly pursued did not burst upon the earth until I was on my way back to London.

In Paris the weather is described as dull, with intermittent gleams of sunshine, and so far there has only been one shower to-day—a phenomenon for which the inhabitants of this gay metropolis are devoutly thankful. Deplorable accounts, however, continue to come in of the devastation caused to the crops throughout the provinces. M. Risler, the President of the Agricultural Society of France, than whom no better authority could be found, frankly describes the situation as bad. To begin with, the hay is completely spoiled. Before this deluge commenced there had been a slight drought, but now it is impossible to dry the grass that has been cut. The cattle are feeding on it as it lies, and soon the supply will be exhausted. Ere long the peasants will be compelled to kill their animals, and meat will be at a discount. As for the corn, it cannot ripen, and the bakers will be obliged to buy home produce at a very high rate and to raise the price of their loaves. Farmers, in their turn will be confronted with the competition of the Russian and Hungarian cereals. The rains have proved beneficial to the Beet-root crop, the prospects of which would be excellent but for the untimely appearance of the little insect which preys upon it. Potatoes, on the other hand, are simply rotting in the ground. As regards the Grapes, M. Risler is of opinion that the vintage will be of inferior quality this year. He says that as matters at present stand French agriculture has already sustained a dead loss of half a milliard of francs, but that if the bad weather lasts for another month the crisis will attain dimensions which he cannot contemplate with calmness. Such a catastrophe would mean "short commons" and hardships for many. In fact, the outlook is as unpromising as it well can be.

RECENT RAINFALLS.—According to *Bell's Weekly Messenger* the amount of rain reported by the Meteorological Office on Thursday, August 2nd, was 1.26 inch measured at Brixton, while at Greenwich the amount was 1.29 inch. The average total fall for August is 2.26 inches, so that in the one day the amount measured was considerably more than one-half the average fall for the whole month. This is the fourth time since June 26th that upwards of an inch of rain has fallen in less than twenty-four hours in London and its vicinity. In July the total fall of rain at Greenwich was 7.09 inches, which is rather more than three times the ordinary average, and is 1.20 inch in excess of the largest previous fall on record in July; and since 1813 there have been but four previous years with a fall for the month in excess of 5 inches. In June and July the total fall of rain at Greenwich was 10.45 inches. There is no instance since 1813 of a larger rainfall for these two months than 8.49 inches, which was measured in 1880, and there are only thirteen years in all with the rainfall for June and July in excess of 6 inches. In all but four instances out of the thirteen these excessive rains were followed by a wet August, so that the outlook is not very encouraging. From June 26th to August 1st—a period of thirty-seven days—the fall of rain at Greenwich was 10.60 inches, whereas the ordinary total for the whole twelve months is less than 25 inches, and last year was less than 20 inches.

Writing to the *Standard*, Mr. J. Kelway, Langport, Somerset, says :—"The amount of July rain at Eltham, 'usually a remarkably dry district,' has exceeded the rainfall at Langport, which is an unusually wet one, by 0.12 inch. The rainfall here amounted to 6.62 inches in twenty-four days on which rain fell. Two of these days of rain amounted to over an inch each—1 inch on July 30th, and 1.16 on July 8th. Three waterspouts are reported to have burst in the vicinity on July 30th."

Mr. Warwick Stunt, Rochester, also remarks :—"It may be interesting to some of your readers to know the amount of rainfall we have had here the last thirty-six hours, and which has amounted to 2.66 inches. The greatest fall took place on Wednesday, August 1st, from 9 A.M. up to 3 P.M., when I registered 1.32 inch. This was probably the end of a waterspout which I am told burst in the Medway river about three miles from here."

Mr. R. GRAY observes :—"The rainfall for July at Chevening, Sevenoaks, elevation 360 feet, with a southern aspect, is 6.58 inches. It would be interesting to know the rainfall at other places for the same month."

Mr. J. B. DIMBLEBY, Memorial Hall, London Street, Bethnal Green, London, E., sends the following on "Weather Causes and Effects" to an evening paper :—"Respecting the weather cycle of nine years, will you allow me to say that what led me to its discovery was the observance of certain astronomical causes, and when I looked for the effects I found them in excessive rainfalls. The causes are—1, the moon on the same level with the earth; 2, her nodes in a direct line with Great Britain; 3, her position in perigee, or when nearest to the earth. The effects are—1852, a rainfall of 38 per cent. above the average, the wettest year on record; 1861, floods, drowning people in their houses and sweeping agricultural produce away in the north, associated with cold and a rainfall of 18 per cent. above average; 1871, 21 per cent. in excess; 1879, cold, and 16 per cent. above average; 1888, probable 40 per cent. The present year is similar to 1816, a remarkable ninth, which for cold and wet produced a famine in Paris. If this ninth-year cycle be extended, it will pick up all the wet and cold years and severe winters with much snow."

EVENTS OF THE WEEK.—On Friday, the 10th inst., the Royal Botanic Society will hold their anniversary meeting in the Regent's Park Gardens. A meeting of the Royal Horticultural Society's Committees is announced for Tuesday, the 14th inst., a show at Claycross also being fixed for the same date. On Wednesday, August 15th, shows will be held at Reading and St. Albans, while on the 16th, Maidenhead, Ludlow, Aberdare, and Abingdon Societies have their annual shows.

— AS will be seen from the WEATHER NOTES on the preceding page an extraordinary rainfall has been recorded in some parts of England, and we shall be pleased to receive further particulars of the effects on garden crops and flowering plants.

— THE Rev. F. D. Horner desires us to announce that the NORTHERN SECTION SHOW OF THE NATIONAL CARNATION AND PICOTEE SOCIETY is postponed to Saturday, August 18th, and will be held at the Royal Botanic Gardens, Manchester, under the auspices of the Royal Botanical Council.

— A WREXHAM correspondent sends us a strange example of a FASCIATED ASPARAGUS STEM. It appears to have been formed by the combination of a number of small stems, the peculiar flattened production resulting being 3 to 4 inches broad, about half an inch thick, and a length of about 2½ feet is twisted into a series of close short coils.

— THE POTATO DISEASE.—"C. O." writes : "The Potatoes in the Isle of Wight are sadly smitten with the disease, which will be a great loss to the allotment holders, who reckon to pay their rents and labour, and keep some in store for their winter consumption of the produce. It spread rapidly from the early and midseason varieties on to the Magnum Bonums, Imperators, and other late varieties. I have advised pulling the haulm to partly save the crop, as the writer of the excellent leader on the subject advised in last week's Journal. It is a question of time with some, whose labour depends on their own hands, but to employers of labour it is the most profitable that men could be put to, and not a day should be lost." It was only advised in the

article mentioned that the haulm of early varieties nearly ready for lifting should be pulled.

— ANNUAL OUTING.—We are informed that Messrs. John Laing and Sons' (Forest Hill Nurseries) employes, to the number of eighty, spent a most enjoyable day on Friday last (August 3rd) at Brighton.

— FROM Mr. W. Dean, Solihull, near Birmingham, came specimens of his AURICULA-EYED SWEET WILLIAMS, which are very distinct from the ordinary types, the ground colour being rich magenta, a large clearly defined pure white centre, and a wire margin of white.

— GARDENING APPOINTMENT.—Mr. G. Waller, for nearly three years general foreman at Billingbear Park, Wokingham, has been appointed head gardener to J. Godman, Esq., Park Hatch, Godalming, Surrey.

— THE exhibition of TUBEROUS BEGONIAS OUT OF DOORS at Messrs. J. Laing & Sons' Forest Hill Nursery will be a little later than usual this year; but the plants will be in their best condition in the course of another week, especially if the weather continue fine and dry.

— THE BROOKFIELD HORTICULTURAL SOCIETY recently held their fourth annual Cottagers' Show at Highgate, when no less than 300 exhibits were staged as against 250 in the preceding year, ample evidence that the Society's efforts are appreciated in the district. Special encouragement is given to the cottagers cultivating allotments in the neighbourhood, and a considerable improvement has already been afforded by stimulating a little healthy rivalry. The President is the Rev. C. T. Ackland, and the Hon. Sec. Mr. F. Marshall, 7, Woodsome Road, Highgate Road.

— PEACHES IN AMERICA.—It is said that 8,000,000 baskets of Peaches are expected from Delaware and Maryland this season. It will be the largest Peach crop ever gathered. Last season the same territory furnished only 1,500,000 baskets, and the whole crop, including that of New Jersey and the Hudson Valley, amounted to only 4,500,000 baskets. They are packed in neat crates holding twelve dozen Peaches, and each Peach is kept separate by pasteboard partitions. In England the outdoor Peach crop is very irregular; in some districts the Peaches on outside walls are very satisfactory, and in others the crop is practically lost.

— IN the grounds of EASTON LODGE, DUNMOW, the residence of Lord and Lady Brooke, a successful Cottagers' Exhibition was held on Wednesday, August 1st, in which over 200 competitors took part. Plants, flowers, fruit, and vegetables were largely represented by exhibits of capital quality in such a season as this. Prizes were also provided for the best cottage or allotment gardens in the seven neighbouring parishes, sixty-two being entered for competition, all of considerable merit, and in one of the parishes the gardens have the reputation of being not only the best in the county but amongst the best of their kind in England.

— REFERRING to CHRYSANTHEMUM MULTICAULE "D. S." writes :—"Unlike most of the other annual Chrysanthemums this is a very dwarf and exceedingly pretty one, growing only a few inches high with small foliage close to the ground, slender footstalks, and small rich yellow flowers, resembling a Buttercup. I sowed the seeds in a cold frame early in April and planted out the end of May, and I am much pleased with it. As a miniature Chrysanthemum this will be welcomed, and it is useful for small beds or in various other ways. Most of the taller growing kinds are beautiful, but somewhat unwieldy in windy weather, but stormy weather seems in no way to affect C. multicaule."

— "M. C. A." writes :—"I noticed in last week's Journal some notes in reference to LARGE MELONS that one of your correspondents was producing, and it occurred to me that this new departure on his part was hardly in accordance with the general tenour of his writings, in which, as far as I gather, he generally depreciates monstrous productions, and in that respect I quite agree with him. Large Melons above most fruits are, to my mind, great mistakes. I was once foolish enough to grow a few of these unwieldy things, and one, a particularly fine fruit of about 14 lbs., was carefully packed in a specially made box and consigned to the family then in town. A few days after, amongst other notes from head-quarters, was one to the effect that 'the Melon of magnificent proportions duly arrived in excellent condition, and was

much appreciated—by the servants.' As can be imagined this concluded our attempt at the production of these large fruits."

— It is with much regret that we hear of the death of Mr. J. J. JONES, of Abberley Hall, Stourport, which occurred at Carlsbad on the 5th inst. Mr. Jones took great pride in his garden and in the improvement of his estates. He had recently added Orchid houses to his glass structures, and it was his intention to have gardening represented in the best manner in the several departments in charge of his able and trusted servant, Mr. Arthur Young. Mr. Jones was a gentleman of wealth and taste, and animated with a desire to have everything he undertook well done, not withholding the requisite means for accomplishing the object in view. He leaves a widow but no family.

— CONCERNING *MIMULUS CUPREUS* PRINCE BISMARCK Mr. W. Dean remarks:—"This charming variety of a very dwarf miniature *Mimulus* was received by me from Germany in the spring, and the seed sown in April and pricked off in the usual way. Many of your readers will probably know *Mimulus cupreus*, a pretty bright rosy scarlet flower, small in size, with a dwarf habit of growth and small foliage, but very few know what a very lovely bedding plant it is. Mr. Hewitt, of Solihull, near Birmingham, who retired from the nursery business a few years ago, has a long border of it which stood out all last winter, and it has been a brilliant spot in his garden, and with fine weather will be again, but constant rain has served it as it has done many other things. Prince Bismarck is of a deeper richer colour, a superb variety, and amateurs may well note both as something to be looked after."

— "B" writes:—"A new FRENCH CABBAGE worth noting is 'Express.' I sowed a pinch of seed of this variety early in March, and nice heads are now ready for cutting. It is of dwarf compact habit, and rather larger than the Nonpareil type. Another Cabbage coming into prominence in the north is Walker's 'Imperial.' This is not so well fitted for a gentleman's table, but for market work it is most excellent, and for gardens where large vegetables are wanted it may well be worth a trial. With other novelties I had among Lettuces one named 'Balton de Bougival,' a Cos variety of large size, larger than Hick's, and turning in for use rather earlier. Those in want of a big variety should have this." [Vilmorin's Express Cabbage was certificated at Chiswick on the 11th ult.]

— THE KEW BULLETIN FOR AUGUST is devoted to a summary of colonial reports in reference mainly to the cultivation of tropical fruits. The Colonies concerning which information is published are Jamaica, Bahama Islands, Barbados, St. Lucia, St. Vincent, Grenada, Tobago, Trinidad, and British Guiana. From twenty to forty distinct fruits are named for each colony, and in several cases it is stated at what time they ripen, the amount available for export, with approximate wholesale and retail prices. Several incidental matters of much interest are also included. Thus under the Bahama Islands it is mentioned that the Pine Apple crop amounts to six million fruits, the wholesale local prices being 2s. per dozen for the pick of the fields, others ranging from 1s. 6d. to 9d. per dozen. Of the Mango over one million fruits are consumed locally.

— LEEDS PAXTON SOCIETY.—At the ordinary meeting of the above Society held at the "Grand Restaurant," Boar Lane, on Saturday July 28th, the President in the chair, and Mr. T. H. Wood in the vice chair, Mr. Gartery, Secretary of the Rotherham Gardeners' Mutual Improvement Society, read an excellent paper on the "General Cultivation of the Rose," in which he gave a lucid and full description of his system of growing this favourite flower. So thoroughly practical was paper that beyond a few questions being asked the lecturer (which were promptly answered) no further criticism was offered. On the motion of Mr. Frankland, seconded by Mr. Brown, and well supported by several of the members, who all spoke in the highest terms of the pleasure they had had in listening to the paper, a hearty and unanimous vote of thanks was accorded to Mr. Gartery for his lecture. A good collection, of Roses (considering the season) contributed by the lecturer and members, graced the table and added to the pleasure of the meeting.

— "J. R. S. C." writes, "In reference to the query put by your correspondent, 'W. T.' I may remark that the history of the 'CUCKOO-SPIT' INSECTS, FROG-HOPPERS, or CERCOPIDÆ, has had no new light thrown upon it recently. As showing the variations which occur, I may

note that though he found the tribe common this year, in this locality there are fewer than usual. We do not yet know where the eggs are deposited by this group, nor indeed precisely when, but it may be assumed the egg-laying operation is completed in the summer, and probably the eggs are placed singly. The habits of the young larva or grub are not positively ascertained; some think at first it is partly or totally buried in buds or expanding leaves before it secretes froth. There would be nothing unusual in a carnivorous fly, such as the slim emps or the more robust syrphus seizing a daddy-longlegs, as they prey upon larger and stronger insects. I presume he means by the phrase a crane fly or tipula, for this odd term is sometimes applied to other insects."

— "J. H. W.," in sending three BESS POOL APPLES for our inspection, remarks:—"After being gathered nine months we consider them good; indeed, it is the best all-round Apple we grow, being excellent both for cooking and dessert, and as a rule the trees bear well when well established. There will be few Apples in this district (Leicester) this year, the trees present such a stunted appearance, and they have been badly attacked with caterpillar. Pears and Plums are moderate, Gooseberries and Currants abundant, Strawberries very scarce and badly flavoured owing to excessive wet." One of the fruits received was quite firm and all good. We have had many similar gathered from a very large tree, but it was long before it commenced bearing. It is stated in the "Fruit Manual," on the authority of the late Mr. J. R. Pearson of Chilwell, that his father once sold the crop from seven large trees of Bess Pool for £70, yet the son considered the variety to be "anything but a profitable one to plant." Still, a large orchard tree in bearing is useful, and there are not many persons possessing one who would be inclined to cut it down, though few, we suspect, would plant young trees for "profit."

— THE PRICKLY-HEADED POPPY.—The prickly-headed Poppy, though one of our common British Poppies, affords a marked contrast to the common scarlet Poppy. It is the weakest in growth, and ordinarily the smallest of all our Poppies. Though not unfrequently met with in cornfields and on waste ground, it is scarcely so common as the common scarlet Poppy; while it does not by any means force our attention to it by its brilliancy, as that species does. It is an annual. The foliage is scanty, the leaves much simpler in form than in the common species, the segments into which they are cut being few in number. The flowers have four petals, and these, from their great length in proportion to their breadth, give the flower a very decided cross-like form, instead of the circular form that, from the greater breadth of the petals, is seen in the other species of the genus. The red is by no means so intense as in the common scarlet Poppy, and each petal has ordinarily a rather large and conspicuous dark, almost black, spot at its base. The capsule that succeeds the flower, and contains the seeds, is long and cylindrical, and has its upper half studded with bristly hairs. The plant will generally be found in flower during the months of May, June, and July. The botanical name of the prickly-headed Poppy is *Papaver Argemone*. The generic name is open to a certain amount of uncertainty. It was first bestowed on the genus by Linnaeus, and in many cases the motive that led to the adoption of the various names by the older botanists is now obscure. — (*Cassell's "Familiar Wild Flowers."*)

RHODODENDRON CULTURE.

(Continued from page 102.)

AMONG the soils which are most to be avoided are those containing much calcareous matter; for useful as it is to many plants, an abundance of it is fatal to the well-doing of Rhododendrons. It is next to hopeless to attempt the cultivation of the plant in chalky districts or where limestone prevails. I will now pass on to another kind of soil which is said not to be so detrimental to the plant, and in which it is asserted by many that it will succeed well—I mean a clay soil, but I have seldom seen a satisfactory growth in soils of this class; in fact, the places are so few where any approach to success has been made in such, that I have never recommended Rhododendrons being there tried, except in cases where they seemed to be a necessity. Clays, however, differ in their chemical qualities, and some may be more suitable than others, and may answer for the common kinds of Rhododendrons, but I do not advocate an extensive plantation on a stiff clay, and to mix clays with lime, as is often done for agricultural purposes, makes the soil less suitable. A clay not containing too much calcareous matter may be improved by mixing with it yellow sand in large quantities, as the latter often contains sufficient ferruginous matter for the Rhododendron, while a bright orange

sand too often contains more than enough. Much circumspection, and a knowledge of the character of the clay, are indispensable before acting in the matter. It is not easy to explain what are the features of a clay which may be converted into a fitting bed for the Rhododendron; one from which bricks are made is rarely suitable, especially if in burning those bricks shrink very much, but the stiff soils where the Brake Fern is found luxuriating may often be advantageously planted with Rhododendrons.

I have mentioned that the hard stone of the oolite formation, mingled with earth of a kindred description, often furnishes a singular but good soil for this plant; a not less suitable one is often met with where sandstone prevails, and I have seen plantations of this plant entirely amongst the refuse of a freestone quarry, as it was called in the north of England, differing merely in its component parts from the Bath stone so extensively used about London. This sandstone debris seems well adapted for the growth of the Rhododendron, and where it abounds the plant may be tried with every prospect of success. Indeed, I am not sure but crushed sandstone may be used with advantage in those cases where an artificial compost is necessary, or has to be added to the clays above referred to.

Other descriptions of soils might be discussed, but I have said enough to give the general reader an idea of what is suitable for the growth of the Rhododendron, or rather the soils are described in which it will thrive tolerably well, while I have attempted to point out those of a contrary description. I shall now turn to another phase of Rhododendron cultivation—one to which less attention has been hitherto paid than to soils—and that is the rearing of plants.

PREPARATION OF THE YOUNG PLANTS FOR PLANTING OUT.—Simple as this may appear, I believe it has more effect on the ultimate success of the plantation than is often allowed. It is not by any means sufficient to order a number of plants from a nursery and plant them at once; such a course has seldom been so successful as desired, and a casual glance at once explains why. In general the Rhododendron is only grown extensively in the trade by nurserymen occupying ground exactly suited to their wants, such as a good dry peat, vigorous growth being the result. Plants are ordered for some place a long distance off, and to be planted in a soil not by any means so well suited to their wants as that from which they came, and the distance being great the carriage is likely to become heavy; to lessen the expense the ball of earth attached to each plant is reduced to the smallest size consistent with the plant's living. Now, when we take into consideration the reduced size of the ball, and the indifferent soil it is removed to, we can hardly be surprised that considerable time is lost before the plants become established in their new home, and it is not unlikely that many will die under the ordeal. The remedy for this state of things, especially in the case of the common kinds, as *Rhododendron ponticum*, is to obtain a quantity of seedlings with half a dozen or more full-sized leaves on each, and plant them out in a nursery bed, in ground resembling that which they are ultimately to occupy. After having been planted about two years they will have become bushy plants, and may be taken up with balls entire, as their removal to their ultimate quarters is not a serious affair when they are on the spot, and may be said to have become naturalised to the soil and other conditions of the place. Those who plant *R. ponticum* extensively for game cover or undergrowth, I strongly recommend to adopt this plan.

A further recommendation in favour of the foregoing method is, that in places where rabbits are very numerous, few, if any, plants escape their destructive propensities, and it has often been asserted that *Rhododendron ponticum* is proof against them, but those who make the assertion have perhaps never witnessed those prolific marauders in such numbers as are met with in some localities, or they would have seen that this plant, though suffering less than many, is not exempt. I have often been led to think that where new plants from a distance are brought near rabbits they are the first to suffer, while those of home-growth escape. I suppose it is the novelty that accounts for the greater injury done; but I do not mean to assert that the home-reared plants all escape, but they certainly suffer less than imported ones; besides which, it very often happens that the latter have been growing more closely together than the others have, and a more delicate set of side branches may in some degree account for it.

As I only intend to explain the main points in the cultivation of the Rhododendron, it is not necessary to enter into details respecting the many varieties now grown. Persons who are doubtful of the soil or situation suiting them had better begin with the common ones first. The better-known Rhododendrons are likely to succeed in a soil and situation falling short of what may be called first-class; but most of the varieties generally called "hybrids," including the bulk of the named kinds, may be grown in soil such as I have described, and as a class they afford perhaps as great a display of floral beauty as anything in the gardening world, not even excepting the gorgeous Indian *Azalea* and the bedding *Pelargonium*, while as evergreen shrubs they are exceeded by few in point of long-continued beauty. *R. ponticum*, at least, may be said to be one of the hardiest plants we have in its capacity of enduring our winters, and most of the hybrids are equally so. I hope therefore where opportunity offers that the cultivation of this plant will be extended, and that groups of it will be planted in woods and other places from which cattle are excluded. For lining the sides of drives or roads through similar places no plant can be more appropriate, for where the soil is suitable, and it has had a fair start, it generally maintains itself against most ordinary vegetation. Wastes

devoted to the rearing of game might also have a few specimens of this plant, not scattered singly, but arranged in groups; and if they were looked after for a year or two at starting they would take care of themselves afterwards. It is in such wastes that they thrive best; a trial of it is there well worth making. The sites for this plant are so many that there are few persons having the means who might not find a situation in which to try it and have the pleasure of unexpectedly meeting with a clump of this plant, say at the end of May, when it is in flower.—R. J. B.

SEASONABLE PLANT NOTES.

LILIUM CANDIDUM.—To increase the stock of these in pots lift bulbs from the open borders directly they have flowered. Good sized bulbs may be potted singly in 6 and 7-inch pots, or four may be placed into 10-inch pots. Give liberal drainage, and employ a compost of good fibry loam three parts, one part of leaf mould, one-seventh decayed manure, and a liberal quantity of coarse sand. The old flower stems may be cut off close to the top of the bulbs. Press the soil moderately firm into the pots, and cover the bulbs with one inch of soil. They will do outside, but start better if they can be placed in cold frames, so that they may be protected from heavy rains until they commence rooting and growing again, which will be in a very short time. When this takes place they will be as well outside as in frames, only be careful to house them before the approach of frost. All who have not suitable bulbs can now obtain imported ones, which, if they are to do well the first season, should be potted directly they arrive. Considerable injury is done to this Lily if the bulbs are kept out of the soil for any length of time, as it is natural for it to commence growth at once after flowering.

ASTERS.—Plants from seed sown late may be lifted and placed in 5-inch pots; if five or six are placed together they are very effective for furnishing purposes late in the season. Quantities of late plants are being lifted and placed moderately close together in positions where they can be protected from heavy rains by frames. These afford a useful supply of flowers for cutting long after the general stock of outside plants have flowered. East Lothian Stocks from seed sown in April may also be lifted, but these must be placed singly in 6-inch pots. Arrange them in the shade for a few days until they become established, then grow them in an open sunny position.

CHRYSANTHEMUMS.—Early flowering varieties are swelling their flower buds rapidly, and if a few are wanted in bloom place them inside in a cool airy house where they will enjoy full sunshine. These, as well as all varieties, must be carefully but liberally watered; weak stimulants may be freely given. The plants grown for the production of large blooms will now need constant attention until all the buds have been taken. As soon as they are formed remove the lateral growths that start from the axils of the leaves near their base; these are generally three in number, and must be taken out with the point of a knife directly they can be seen. All laterals below them must also be removed as they show, so that the plant can concentrate all its strength on the production of the flower. Top-dress the plants with rich material directly the buds have been taken to keep the roots thoroughly active. Feed frequently, but do not apply stimulants in a strong state. Overfeeding does more harm than good by bringing the roots to a standstill, and flat instead of deep globular flowers are the result. Cuttings from the tops of plants that have been allowed to grow may still be rooted. Large-flowering kinds should be rooted singly in 60's and be allowed to carry one bloom only, while small-flowering varieties may be inserted five or six together in 5-inch pots. These will soon root in cold frames if shaded from the sun. Directly they are rooted place them in a sunny position.

TREE CARNATIONS.—Remove flower buds from the earliest plants as they appear, and encourage them to grow as strongly as possible. Water the plants carefully; at the same time do not allow them to suffer by becoming dry at their roots. Weak stimulants may with advantage be given occasionally. For this purpose clear soot water, or liquid formed by steeping cow manure in a tank, will suit the plants well. Vigorous plants that are not required to flower before spring may be placed into 7-inch pots at once. Use for a compost good loam, sand, and one-seventh of decayed manure. If aphides infest the plants syringe with or dip them in a weak solution of tobacco water. Layer such varieties as *Gloire de Nancy*, *Souvenir de la Malmaison*, and others for flowering in 6-inch pots early next season. Plants from which the flowers were removed in spring and transferred into 8-inch pots may now be placed into 10-inch, in which they will be flowered next season. These, if well cared for, will be imposing plants when in flower for the conservatory, in fact any position.—B.

OVERCROPPED FRUIT TREES.—Very heavily cropped trees, or any that have perfected a heavy weight of fruit, and which give signs of being overworked, will be much benefited by a good soaking of farmyard liquid manure, or failing this a liberal sprinkling of guano, superphosphate, sulphate of ammonia, or some other kind of artificial, ought to be washed in. Unless the trees are thus assisted, many of them, notably Plums and Pears, will have been or will become so much exhausted as to be unable to perfect a crop next year, even if they flower freely. Reckless overcropping and starvation at the roots is most to blame for the inability of many trees to perfect a crop every season. Properly treated, nothing but the most unfavourable weather will prevent profitable crops being annually obtained.—W. M.

THE DALMATIAN IRIS.

THIS beautiful species has been known to me under the name of *Iris dalmatica* for at least twenty-five years. I am aware that it is now

Foster has given great attention to the *Iris* family, and I feel certain he is in a position to clear up the mystery, being extremely accurate. I recollect sending a bulbous species to an authority one year, who called

FIG. 15.—THE DALMATIAN IRIS.

classified as a variety of *Iris pallida*, still it is quite double the size in flower, foliage, and height to the so-called typical species. Anyway, whatever may be its family connection it holds its own in being by far the most strikingly beautiful of the bearded section of *Iris*. Professor

the *Iris* by a well known name, and to which it certainly had no relation. The next year I sent it to Professor Foster; he at once recognised it as a scarce species, and only of recent introduction.—WINTON.

[The illustration (fig. 15) was prepared from a flower supplied by

Mr. Fred. Horsman of Colchester, and was one of the most handsome we have seen; the colour a delicate mauve and rich blue.]

THE ROMANCE OF SEED-SOWING.

EVERY country child knows the appearance of a "Dandelion-clock," and has tried to "see what o'clock it is" by the number of puffs needed to blow away the round head of soft down at the top of the flower-stalk in autumn. Equally familiar is the smaller tuft of grey down on Groundsel after flowering, although most people do not know that the botanical name of Groundsel is *Senecio*, from the Latin *senex*, an old man, given to it on account of the colour of this down. Most of us can recollect the innumerable tufts of similar material flying all over a Thistle field long after butterfly and bee have done their work among the purple flowers. We have all seen Sycamore "keys" strewing the ground in June and July, and brown Ash "keys" persistent on the parent tree when October winds have blown nearly every leaf from its hold. The bonnie autumn berries in our woods, and the fruits of Blackberry and Strawberry have been gathered by children of younger and older growth many a time and oft. How many of us ever stay to inquire why Groundsel and Thistle possess their downy tufts, why Ash and Sycamore produce their "keys," or why many of the trees and plants are dressed in fruiting time with crimson and scarlet, purple and olive? Not only in order to the uses we make of them, we may be quite sure. "Dandelion globes" and "Thistledown blows" do not exist only to tell the time of day to a four-year-old child, or "he loves me—he loves me not" to the maiden of seventeen. Ash and Sycamore have "keys" for some other purpose than to form graceful, drooping clusters in June. The fruits and berries are not solely for decoration and digestion by human gatherers. Were these their only reasons for existence that would soon terminate in all probability. All these, and many others that we could name, gladden and delight us in various ways, as do the flowers that come before each one of them; but, as with the flowers, so with down-tuft and "key," berry and fruit; they all have their several missions to perform, in order to perpetuate the very existence of their species, and to hold their own in the battle of life. Acknowledging that while they last, they are, in a thousand forms and ways, beautiful and useful, I wish to try to show the definite uses of these "common things," and of some curious and wonderful contrivances to be found in plant life all around us. To come to the subject matter of this lengthy introduction, let us look for awhile at the various methods by which, either through external agency or intrinsic power, trees and plants manage to disperse their seeds, and to secure for their offspring a suitable home, and a fit and proper environment.

The first question that naturally arises in many minds will probably be, Why try to scatter or disperse them at all? Why not let them take their chance, and simply fall to the ground immediately underneath the tree, shrub, or annual, as the case may be, there to germinate and grow up into their parents' likeness? This is quite easily answered. In the case of trees, if all the seeds fell round about the trunk they would stand a poor chance, for if they ever germinated at all, the young seedlings would get very little sun, and a great deal too much overshadow, and would be further harmed by the "drip, drip," from the branches. In the case of both trees and plants, moreover, the large quantity of young plants would choke one another in the struggle for life; indeed, this not seldom occurs with some of our garden annuals, as we can easily prove for ourselves. Again, many plants soon exhaust the earth of certain mineral materials, and if their seedlings attempted to grow in the same soil, they would fail, the parent plant having used up the chief portion of such substances.

A parallel to this is found in the fact that farmers do not grow the same kind of plant for successive seasons in the same field, but vary the sort from year to year, choosing plants that draw different materials from the soil in consecutive years. "Rotation of crops" we call it, but it is not our own invention. We took centuries to find it out. The plants and trees knew of it long ages ago, and so were led to develop the various methods of ensuring a speedy and effectual transit of their seeds to other and better soil, where they might find their needed foods in rich abundance. Of course, in certain cases—notably of some very small annuals, whose roots practically exhaust the soil but little—their seedlings find a good position at once, and manage to flourish; those growing on sloping grassy downs or cliffs, too, stand a better chance, inasmuch as their seeds fall on ground at a lower level than that drawn on by the parent plant. Examples of this are seen in our wild Snapdragons, Wallflowers, and others growing in such profusion on railway banks or on sloping limestone cliffs. For the most part, however, those plants flourish best that develop tendencies that tell in the direction of effectual dispersion of their seeds.

I must not omit mention of one thing before detailing the methods of dispersion. Seeds must not be scattered until they are "ripe" and ready to set up their own independent existence. Hence we find all sorts of devices for protection of seeds during their growth. Some are enclosed in a thick, hard shell, such as Hazel Nut, Beech Nut, Spanish Chestnut, Cocoa Nut, Monkey Pot, and many others. Some are hidden away under overlapping wooden scales, such as the cones of Firs and their allies. Some are surrounded by thick fleshy coats, such as Horse Chestnut, Almond, Apple, Cherry, and the like. Walnut has a covering which is not only tough, but bitter to the taste. Mignonette, one of the Leguminosæ, has its pod covered with stinging hairs. Some have the calyx closed over the ripening seeds, as Winter Cherry, Strawberry-

headed Trefoil, Herb Robert, and some others of the same order. The wild Rose fruits nestle inside the hollowed-out flower stalk which forms the hip, whose scarlet colour stands out in beautiful relief on the bushes in September and October. Many Clovers have the withered corolla for a covering to their seed-containing pod, and perhaps no plant better knows how to protect its progeny than Gorse, whose hair-covered pods defy wind, storm, and insect, until the seeds are fully ripe and ready to be scattered by the burst of the pods in the August sunshine.

Finally, there are some plants which by movement insure protection. The little *Linaria* of our rockeries and walls—"Mother of Thousands," as West-country folk call it, revels in sunshine, but as soon as it is fertilised, it pushes itself into some cranny or nook, hiding its seeds away until they are ripe. Dandelion keeps its stalk bolt upright during the three or four days of flower expansion, but it bends down close to the earth, and buries its flowers among the grass for ten or twelve days while the seeds are getting ripe, afterwards becoming erect once more, for a reason which we shall presently consider. Now let us see what are the agencies by which seeds are sent or carried on their journeys. There are four chief ones, besides one or two minor methods seen in only a few instances. We will take the four principal ones first of all.

I.—WATER.—Under this head I include the action of rivers and ocean currents. Comparatively few seeds are carried by water, owing to their being, as a rule, unable to withstand prolonged immersion; but it is still true that the agency of water is a very important one, especially in the form of marine currents. Many seeds are small and light enough to need no further adaptation; but in the case of the larger kinds they must not only be able to answer to the law governing floating bodies, too well known to quote here, but they must also be absolutely impermeable to water itself. The Cocoa Nut rind is woody and fibrous. Hence these fruits can easily withstand the action of sea water and protect the seed within. They may be carried for thousands of miles over the sea, and yet when stranded the seeds can readily germinate. In this way we account for the wide range of this Palm and its presence on the main coral islands of the Pacific. Many seeds and fruits have thus been carried by the great current of the Gulf Stream from Mexico to the marshes on Ireland's western coast, to the lakes of the Hebrides, and to the Norway coast. Others have gone by currents from Madeira to the Canaries and thence to the African borders.

Rivers again act in a similar manner. Seeds and fruits are brought down from the mountainous districts and deposited among the level plains and grassy meadows, and thus we can easily account for the presence of such species in what seem to us strange habitats for them. Both in marine currents and in rivers the action of water in carrying seeds to any purpose is most effectual when the direction is from W. to E., or the opposite, because then the seeds are kept pretty much within the same latitude and therefore in similar climates. Hence they will grow and flourish where they eventually settle as well as they did in their former home. Currents going from N. to S. or S. to N. take them into unfavourable surroundings, and then they mostly perish.

Some seeds are specially fitted for water transit by the presence of air bladders variously developed—e.g., those of Water Lily. Others have a smooth rind with an oily juice, such as those of Arrow Head (*Sagittaria*), of our water ditches. This peculiarity is, of course, of advantage in swampy and marshy districts, where the water dries up in warm weather, and the courses of the current vary so much.—H. W. S. WORSLEY BENISON, F.L.S. (in the *Journal of Microscopy*).

THE COMMERCIAL REALISATION OF FRUIT.

(Continued from page 105.)

EXPORTATION OF FRUITS TO THE COLONIES AND INDIA.

THE systematic packing of fruits, coupled with the practice of refrigeration, provides facilities that would enable them to be profitably shipped to the Australian and other markets of the world. The same appliances and means by which fruit can be successfully brought from the Antipodes can be employed in conveying it there. The steam vessels that bring home meats do not utilise their refrigerating machinery on the voyage out, and doubtless they would be pleased to do so. Our fruits, if shipped, would reach there at a time when the colonists have no fruit of their own, and they would readily purchase the consignments. The railways of the different colonies run from all the principal ports to the interior, and reach about 500 stations, most at bush towns, where little or no fruits are grown or otherwise obtainable. An organised export trade could be profitably carried on for six weeks or two months in each year, when our fruits are abundant. Fruits in quantity, properly packed, could be put on board the outgoing vessels at Tilbury Docks from the Medway at from 7s. 6d. to 10s. per ton. Fruits shipped in refrigerators can be insured against all risks—and therefore can be dealt with upon the ordinary commercial basis—that enables financial arrangements to be completed and carried out in connection with shipping documents.

EVAPORATED AND DRIED FRUITS.

Dried fruits are those from which the moisture has been extracted by exposure to the sun, are well known in our markets, and have been largely imported for a very long time; these include raisins, Currants, Figs, Prunes, Plums, Normandy Pippins, French Pears, American Apples, &c. The drying of fruits has not been attempted in England on a commercial scale, but frequently fruits have been allowed to remain and dry on the trees, owing to their value as at present dealt with being insuffi-

cient to pay for picking, packing, and transport; in this the county of Kent is not singular. Evaporated fruits are the product of a system of drying by means of currents of hot air—the practice has been brought into active operation in Canada and America within the past few years for the purpose of utilising crops there, and has proved to be very profitable to carry out. The process is an exceedingly simple one, and is readily applicable to all classes of fruits, from the soft Raspberry and Strawberry to the hardest kind of winter Apples. In practice the Apples are pared, cored, and sliced or quartered by a small hand machine worked by a boy or girl; they are then spread on wooden trays or shelves and placed in a close oven or chambers to which hot air is supplied from a stove or steam coil. Apricots, Peaches, Cherries, and similar fruits are dealt with in the same manner; they are subjected to a current of dry hot air in the chamber for about three hours, during which time they are deprived of the whole of their moisture, are altered in appearance, and become considerably reduced in weight. They can be easily packed, and will keep in good order and condition for an indefinite time. When required for use they simply have to be steeped in water and cooked in the ordinary way, when they will assume their original dimensions and also be found to have retained the flavour they possessed upon being subjected to the process—that is to say, that if evaporated at the orchards immediately on being plucked they will retain all the natural aroma and flavour of fresh plucked fruits, whereas, if they are dealt with after being plucked and marketed, involving a delay of several days during which they will have lost their flavour, then they will only have the flavour they possessed at the time of preparation and no more. It must not therefore be thought that stale fruit can be evaporated and will become fresh in the process, or that unsound fruits will become sound by the same means. This points out the advantages derivable from treating the fruits on the spot in proximity to the orchards where grown. The county of Kent possesses great advantages for profitably working the system of fruit evaporation owing to the large number of oast-houses that exist in every direction that could be readily converted and utilised as evaporators, and thus profitably employed in seasons where they now remain unoccupied. The improvements made to the oast-houses to enable them to be used for fruits would be of material benefit when they were required for Hop-drying. The temperature maintained in the evaporators for fruit-drying ranges from 180° to 240° Fahr., and the time occupied in drying is from two and a half to three hours, varying with the fruits, some of which contain more water than others. Green Apples weigh about 55 lbs. to the bushel, after being pared and cored the net residue weighs about 35 lbs., which quantity, after evaporation, weighs from 6 to 7 lbs. A bushel of green Apples in America or Canada is worth about 7d. to 9d.; the wholesale value of the evaporated fruit there is from 6d. to 7d. per pound, say from 3s. to 3s. 6d.; the cost of labour, fuel, &c., is about 10d. the bushel, therefore by evaporating their fruit the growers of America and Canada more than treble their value, besides obtaining a residue of 20 lbs. of paring and coreings which has a good value as a food for stock, in which form it is much appreciated. Pears turn out about 7 to 8 lbs. to the bushel, and Plums about 12 to 13 lbs.; all other fruits show comparatively similar advantageous and profitable results. In addition to its possession of the oast-houses, the county of Kent furnishes peculiar facilities for the successful introduction and practice of the system of fruit preservation by evaporation on the following grounds:—It has a large quantity of soft and hard fruits that give a long range of season for working. It has a quick communication with the metropolis, to which regular supplies of its choice fruit can be speedily forwarded as selected from the bulk. The large capacity of the oast-houses, in the centre of the fruit-producing district will, by appropriating a vast amount of fruit that has hitherto been forced on the market, make room for the produce of many more orchards than at present exist, and at the same time enable better prices to be obtained for what is disposed of.

CANNING OF FRUITS.

The canning or tinning of fruits is largely carried on in America, at Bermuda, and at Singapore, also to some extent in Australia. Fruits preserved in this form are dealt with in two ways; the first in their own juice, when they are intended for cooking purposes; by the second they are prepared in syrups of different strengths, and are then available as dessert fruits. In the New England States and in Maryland vegetables are also largely preserved, and form a valuable addition to the larders of all American homes. In the State of California dessert fruits are canned and shipped in very large quantities to all parts of the world. It will not be difficult to obtain Californian fruits of every description at any of the leading grocers of Sittingbourne. The cost and charges of tins and cases form a large proportion of the cost of canning, and this system, except for the fruit in syrup, is being superseded by the more economical method of evaporation, as that is found to need but little additional capital from the farmer over the cost of the fruit.

The boiling of fruits in syrups is carried on very extensively in Portugal and in France, and goods made up in that form command very high prices and meet with considerable sale in the West End of London, where they are in demand at seasons of the year when other fruits are not procurable. A considerable quantity of fruits are bottled by our London and some country manufacturers, but, with that peculiar characteristic that applies to the distribution of our food products, English bottled fruits are invariably made up in their own juices, and suitable only for cooking purposes. Compared to the manufactures of other nations, they have a low commercial value, and only enter into consumption where other goods are not obtainable. These are sad facts

to realise in a country whose people pride themselves upon their commercial experience, enterprise, and energy.

The crystallising of fruits by boiling them in sugar that they may be available as a sweetmeat, or for dessert purposes, is very largely carried on in France, whose goods are extensively imported and readily sold in every direction with us at comparatively high prices. This particular branch of fruit preservation is divided into several branches, each having special characteristics, such as crystallising, glacing, candying, &c., &c. The basis of all, however, is much of the same character, and does not require either extensive plant or other appliances; skilled labour is the principal element necessary to produce these goods and pack them for sale. The candying of Lemon and Orange peel is the principal branch of this industry that is carried on in this country.

(To be continued.)

SARCOCHILUS HARTMANNI.

SEVERAL species of *Sarcochilus* have been noted various times, especially at Kew, where they are well grown and frequently attract attention as amongst some of the most distinct and pretty Australian Orchids. In the "Botanical Magazine" for August an excellent illustration of the species named above is given, together with the following remarks by Sir Joseph Hooker. Being of free growth, flowering readily, and lasting well, this and other species of *Sarcochilus* are not likely to remain long scarce in amateurs' collections of Orchids. "This appears to be very near indeed to *S. Fitzgeraldi*, *F. Muell.*; but, as Mr. Fitzgerald points out, the habit is erect, and the very stout peduncles and racemes at once distinguish it. It is a native of mountain woods near Towomba, and at Cairns in Queensland, where it was discovered by Mr. E. Ramsay, F.L.S. Our plant was received from Mr. J. F. Roberts, nurseryman of Kew, near Melbourne, in 1883, and it flowers annually in the cool Orchid house in the early spring.

"Stems loosely tufted, short, stout, with very long strong aerial roots. Leaves three to five, 2 to 5 inches long, hard and fleshy, linear-oblong, tip obtuse or equally or unequally obtusely two-toothed, channelled down the middle, keeled at the back, light green. Peduncle as thick as a goose-quill, as long as or longer than the leaves, sub-erect, with a few distant fleshy ovate green bracts; raceme 4 to 5 inches long, laxly many-flowered; bracts small, triangular, persistent; pedicels a quarter of an inch and short ovary and base of perianth externally speckled with red. Perianth three-quarters of an inch in diameter, sepals and petals sub-similar, spreading, oblong, obtuse, pure white with a few red specks or bars at the base. Lip very small, saecate; fleshy, lateral lobes faintly oblong, obtuse, erect; intermediate very short, conical, obtuse; disk with a fleshy two-lobed callus."

ORCHIDS IN UNHEATED HOUSES.

It is often advised, and rightly, that it is unwise to attempt growing Orchids in greenhouses, but this, of course, refers to houses where hardwooded plants, such as Heaths, &c., are grown, which need an abundant supply of air at all seasons. During the summer however, many Orchids can be satisfactorily grown in unheated houses, and they can be kept healthy during the winter if the temperature can be prevented falling below 40°, or preferably 45°. I have a small house the roof of which is covered with a Black Hamburgh Vine, while on the stages I grow a number of Ferns with a few flowering plants, and amongst the latter are some Orchids, a few of which have flowered excellently this summer. No heat is employed during the summer months, and though our Grapes are late they both colour and ripen well, the foliage affording just as much shade as the Orchids and Ferns require. The best of the Orchids is *Odontoglossum Rossi*, which has even recovered from a rather severe freezing, and flowers each season abundantly, lasting for several weeks. *O. Cervantesi* is not quite so happy, but that also has flowered well this season. *O. crispum* I have in several varieties, and it is thoroughly at home, but not quite so hardy as the preceding. As an experiment I tried *O. vexillarium*, but though it still appears healthy the flowers will not develop, and it will have to be discarded in favour of the others. My most useful and long-lasting Orchid has been *Epidendrum vitellinum*, the rich colour of which afforded a fine contrast with the *Odontoglossums*. *Masdevallias* of the *Lindeni* and *Harryana* types grow and flower freely, and with the aid of a few *Adiantums* we have been able to make up several rather effective little groups.—H. H. M.

VEGETABLES FOR EXHIBITION.

I HAVE read your correspondent's notes under this head (page 66), and upon the whole been much interested in them; but there is one point that I take a decided exception to—namely, in reference to Globe Artichokes. I fail to see the qualifications of this to take at any time a full number of points of any one kind of vegetable. I know it is a favourite with some exhibitors, but I fail to see the merits in any particular. I should class it amongst oddities—place it in the same position in a collection as it usually is in the garden—that is, where Horseradish, Rhubarb, &c. is in the roughest part of the garden. Neither is the Artichoke a popular vegetable, so that at any time I should place many kinds before it. Indeed, I hardly think it equal to a dish of tender and good young Cabbage. Of course, my opinion may be out of the usual fixed course, still I should be interested a little further to see the opinions of a few growers on this point. There is no difficulty in growing an Artichoke. How many per cent. care for it after it is grown? Would not your correspondent himself prefer good Cabbages to it any day?

One vegetable he makes no mention of which is a most deserving one popularly—the Leek. It will stand the severest winter, and is most wholesome if properly used. Certainly it can scarcely be called a summer vegetable, but good early ones might be put on a par nearly with Celery in August. The tastes of judges it is well known vary greatly, and the Artichoke, it seems to me, is one of so little consequence that they are seldom asked for, and I should be inclined to dispute your correspondent's opinion, in a friendly way, on the point.—AN OCCASIONAL EXHIBITOR.

LIVERPOOL SHOW.

THE Liverpool Horticultural Society's Exhibition was held, as usual, in Sefton Park, on Saturday, August 4th, and Monday, the 6th, and, on the whole, was equal to those of previous years. The large tent devoted to stove and greenhouse plants has, perhaps, never been better filled, nor have exhibits been so nearly equal in so many instances. The Show was a brilliant success, but financially it was probably a complete failure, as rain fell before the judging was completed, and continued the remainder of the day. The tents in consequence were practically deserted. This is to be regretted after the heavy losses of last year, the signal failure of the spring show, and just when the Society anticipated widening its base of operations.

STOVE AND GREENHOUSE PLANTS.—In the class for twelve plants, six flowering and six foliage, three collections were staged, and the competition between Mr. J. Cypher, Cheltenham, and Mr. Roberts, gardener to A. Nicholson, Esq., Highfield House, Leek, Staffs, was remarkably close, the former gaining the premier position by one or two points. Mr. W. Finch, gardener to J. Marriott, Esq., Queen's Road, Coventry, was third. The first collection contained *Kentia australis*, *Kentia Fosteriana*, *Crotons Victoria* and *C. angustifolius*, good; *Cycas revoluta*, *Lantana borbonica*, *Erica depressa*, 4 feet through, and a mass of bloom; *Erica Marnockiana*, *Statice profusa*, *Allamanda nobilis*, *Kalosanthes coccinea*, and a good *Phænocoma prolifera*. The second contained magnificent plants of *Kentia australis*, *Cycas circinalis*, *Encephalartos villosus*, *Ixora Williamsi*, 5 feet through and full of flower, and a large profusely flowered *Dipladenia amabilis*. In the corresponding class for eight plants Mr. B. Cromwell, gardener to T. S. Tinnis, Esq., Cloveley, Allerton, was well first with grand plants, amongst them being *Croton Disraeli*, 5 to 6 feet through and a good colour; *Croton Queen Victoria*, considerably larger than the last and superbly coloured, being by far the finest *Croton* in the Exhibition. A good plant of *Gleichenia dichotoma*, 5 feet in diameter, and *Ixora Pilgrimi* were also conspicuous. Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, followed, having a fine *Phænocoma* and *Ixora coccinea*, Mr. Finch being third for creditable plants. Mr. A. Crosbie, gardener to B. Hall, Esq., Dudlow House, Wavertree, was awarded an extra third. For six plants in bloom Mr. Cypher took the lead with *Ixora Williamsi*, *Allamanda nobilis*, *Erica Thompsoni*, *E. retorta major*, *Kalosanthes coccinea*, and *Statice profusa*. Mr. Roberts was a close second, and had good plants of *Ixora Pilgrimi*, *Erica Jubeana*, and *Dipladenia Brearleyana*. Mr. W. Finch was third with much smaller examples. In the corresponding class for four plants Mr. B. Cromwell was first with neat well grown examples. Mr. A. R. Cox second, and Mr. J. Jellico, gardener to F. H. Gossage, Esq., Camp Hill, Woolton, third. For one stove plant in flower Mr. Roberts was first with *Dipladenia splendens*, Messrs. W. Finch and A. Crosbie being second and third, the former showing *Sobralia macrantha*, and the latter *Eucharis amazonica*. For one greenhouse plant in flower Mr. J. Cropper, gardener to H. A. Vlasto, Esq., took the lead with *Hydrangea hortensis*, 7 feet through. Mr. Gowen, Mossley Hill, second with a fair *Kalosanthes*, but past its best.

FINE-FOLIAGE PLANTS.—These were shown in about the usual style and numbers. For eight plants Mr. J. Jellico gained the highest award with grand examples of *Pritchardia pacifica*, *Dion edule*, *Dicksonia antarctica*, *Thunia elegans*, *Lantana borbonica*, *Croton Warreni*, *Croton Countess*, and *Goniophlebium subauriculatum*. Mr. Cypher was second, and Mr. Finch third. For six plants Mr. B. Cromwell was well first with healthy moderate sized specimens of *Gleichenia Mendelli*, *Anthurium crystallinum*, *Kentia Fosteriana*, *Croton aureo-marmoratus*, and *Phoenix rupicola*. Mr. A. R. Cox secured the second place, and had in his collection *Kentia Fosteriana* and *Croton angustifolius* good. Palms need no special comment. The prizewinners for three plants were

Messrs. A. Crosbie, Thos. Jones, and C. Roberts; for one plant Messrs. C. Roberts and A. Crosbie.

Ericas were not numerous, and those staged were below the average. Mr. Cypher was first with fair plants, Mr. A. R. Cox second, and Mr. Roberts third with small examples.

FERNS.—Particularly good were the Ferns, especially exotic varieties, while hardy varieties were scarcely up to the mark. For eight exotic varieties, distinct, Mr. Thos. Gowan was first with a splendid lot of plants that would average nearly 4 feet through them, and in the best possible condition. *Gymnogramma argyrophylla*, *Adiantum Lindenii*, *Davallia scaberula*, *Davallia Mooreana*, and *Goniophlebium subauriculatum* were conspicuous. Mr. B. Cromwell was a good second, having splendid examples of *Davallia tenuifolia Veitchiana*, *D. fijiensis* both very fine, and *Nephrolepis davallioides furcans*. Mr. A. R. Cox secured the last award. For four plants, six or seven collections were staged. Mr. J. Hughes, gardener to D. McIver, Esq., Elmwood, Woolton, Mr. Thos. Jones, gardener to W. Clark, Esq., Aigburth Drive, and Mr. J. Hurst were the winners in the order named. For six *Selaginellas* Mr. Harrison, gardener to Mrs. G. Bateson, New Heys, was first with capital well grown plants. For two Filmy Ferns Mr. J. Foster took the lead with two fine *Todeas*, followed by Mr. J. Jenkins, gardener to J. E. Tinnis, Esq., Mersey Road, and Mr. W. Finch. For six hardy varieties Mr. J. Foster, gardener to J. Brancher, Esq., was first, and Mr. P. Barber, gardener to A. Barnsley, Esq., second.

Begonias were far behind those staged a few years ago, and except the exhibits from Mr. Cox they could only have been termed the poorest of examples. His plants were young, but strong and well flowered. For six plants the competitor named was first, followed by Mr. A. Crosbie and Mr. B. Cromwell. For three, the same exhibitor was again first, the last second, and Mr. James Hurst third. For one plant Mr. A. R. Cox was again first.

Caladiums were good, and for six plants Mr. J. Warrington, gardener to J. Bright, Esq., was first, followed by Mr. J. Harrison. *Achimenes*, *Petunias*, and *Fuchsias* need no special comment. *Coleuses* were good, but too formal. Mr. Gowan was placed first, Mr. Bustard second, and Mr. T. Jones third. *Cockscombs* were good, and Mr. A. Agnew gained the chief honours, and Mr. R. Johnson, gardener to Mrs. White, Derwent Lodge, Wavertree, was first for *Gloxinias*, which were superb. Mr. T. Winkworth was second, and Mr. Agnew third.

GROUPS.—Only four were staged for the six awards offered. In the open class for a group of miscellaneous plants not to exceed 250 square feet, Messrs. R. P. Ker & Sons was the only exhibitor, and the arrangement was in their usual light and effective style, for which the first prize was awarded. In the corresponding class for one not to exceed 150 square feet there were three competitors, and Mr. A. R. Cox was successful with a neat telling arrangement of clean choice plants. Mr. J. Jellico was an excellent second, and at a first glance the most pleasing of the two, but upon close inspection the Judges' decision was found to be right. Mr. T. Jones was third with a heavier group that lacked lightness and colour. *Zonal Pelargoniums* were on the whole good. For six single varieties Mr. Gowan took the lead; for three Mr. D. McKellar was first; for four double Mr. Gowan occupied the same position, and Mr. J. Stoney for six Ivy-leaf varieties which were well done.

ORCHIDS.—The plants contributed for the six prizes offered for these plants were highly creditable to the unsuccessful competitors as well as those that gained the prizes. The competition was very keen, and the plants in every instance healthy and well flowered. For four plants Mr. J. Cypher took the lead with *Cattleya crispa* having six fine spikes; *C. Gaskelliana pallida* was equally good with the same number of spikes. *Saccolabium Blumei* was striking with three spikes, while *Cypripedium caudatum* had two fine flowers. H. Tate, Esq., (gardener, Mr. J. Edwards), was second, and had a fine dark variety of *Odontoglossum Harryanum* with three spikes. Third, Mr. R. Johnson, gardener to Thos. Slatters, Esq. For one plant Mr. W. Tunnington was well first with *Oncidium Lanceanum*; Mr. J. Edward second with *Odontoglossum Harryanum*, having a fine spike of ten flowers; third, Mr. R. Johnson for *Miltonia spectabilis* having twenty flowers.

Table plants as usual were light and of a very suitable size for that purpose. For six plants Mr. C. Evans, gardener to Willwood Maxwell, Esq., Holmfield, Aigburth, was first with *Pandanus Veitchi*, *Dracæna gracilis*, *Croton aigburthensis*, *Croton Chelsoni*, *Dracæna albo-marginata*, and an *Aralia*. Mr. J. Agnew was second, and Mr. J. Bounds third, both showing well. There was a large number of entries in this class.

CUT FLOWERS.—The prizes for these were well contested, especially those offered for stove and greenhouse varieties, but the display of Roses did not quite equal expectations, for they were not of such good quality as we have seen them at this Show. Of forty-eight Roses, distinct blooms, no less than six collections were staged, and the first and second were very close. Messrs. Harkness & Sons, Bedale, secured the premier position with fresh and bright, but rather smaller blooms than those which gained the second award. The names of the whole of the varieties in this collection have been given several times this season, that they need not be repeated here. Messrs. A. Dickson & Sons, Newtonards, and Messrs. R. Mack & Sons were second and third winners. For eighteen blooms of Teas, Hybrid Teas, and Noisettes, three collections were staged; the same exhibitor was again successful, and had good *Souvenir d'un Ami*, The Bride, Rubens, Madame Caroline Kust-r., Madame Willermoz, Lady Mary Fitzwilliam, Francisca Kruger, David Pradel, Alba Rosea, Catherine Mermet, Niphetos, Madame Cusin.

Princess of Wales, Souvenir de Paul Neyron, Grace Darling, Innocente Pirola, Souvenir d'Elise, and Madame de Watteville. Mr. J. B. Hall, Larkwood, Rock Ferry, was a good second, and Messrs. R. Mack third. For twenty-four blooms three collections were again exhibited. Mr. T. B. Hall secured first honours with a capital lot; Mr. H. Pewtress, gardener to A. Tate, Esq., second, and E. H. Stoll, Esq., The Lindens, Fulwood, Preston, the remaining prize. For twelve blooms the same competitor was again to the fore amongst seven exhibitors. T. Raffles Bailey, Esq., Breck Hey, Liscard, second, and Mr. W. Hall, St. George's Mount, New Brighton, third, all showing well. Eight boxes were staged for twelve blooms of any dark variety. Messrs. Harkness and Sons took the lead with superb examples of Ulrich Brunner, followed by Messrs. A. Dickson & Sons with Marie Baumann, and Messrs. R. Mack & Sons third with the same variety as shown in the first collection. For twelve blooms of any light kind no less than nine competitors competed for the three prizes offered. Messrs. A. Dickson & Sons was well first with magnificent blooms of Her Majesty; Messrs. Harkness and Sons second with Merveille de Lyon, and Messrs. R. Mack & Sons third with La France, very neat. For the most tastefully arranged box of Roses, not less than twelve varieties, Mr. T. B. Hall was first with a very effective arrangement of dark and light blooms, which contrasted admirably with the groundwork of *Adiantum cuneatum*. Second, A. Tate, Esq., very neatly arranged, but the intermediate coloured flowers rendered the contrast less effective than was the case in the preceding exhibit. The remaining exhibit needs no special note, for the blooms were poor and crowded together.

Stove and greenhouse cut flowers were probably never shown in larger numbers or in more excellent condition; they were one of the most attractive features of the Exhibition. For eighteen varieties four collections were staged. Mr. J. Cragg, gardener to A. Heine, Esq., Birchfield, Fallowfield, Manchester, was well first with large bunches of *Odontoglossum Lindleyanum*, *Cattleya crispa*, *C. velutina*, *C. Gaskelliana*, *Allamandas*, red and white *Lapagerias*, *Ixora*, *Dipladenia*, *Eucharis*, *Stephanotis*, and *Bougainvillea*. Mr. P. Blair was a good second, and had very fine *Odontoglossum Alexandræ*, *O. Pescatorei*, *Cypripedium bellatulum*, *Oncidium macranthum*, *Disa grandiflora*, *Dendrochilum filiforme*, *Epidendrum vitellinum*, and *Masdevallia Harryana*. Mr. B. Cromwell was third, and had splendid spikes of *Stanhopea insignis*. In the corresponding class for twelve varieties Mr. J. Bound took the lead, followed by Mr. G. Jenkins and Mr. Hurst. Five collections were staged. Hardy herbaceous cut flowers were much the same as in previous years. For twenty-four varieties Mr. W. Bustard was first with an imposing collection, Mr. J. Watson was a good second, and Mr. J. Warrington, gardener to T. Bright, Esq., third. For twelve varieties no less than eleven exhibitors staged, and the winners were Messrs. J. Foster, D. McKellar, and P. Barber. For eighteen Carnations Mr. R. Brownbill, Ravenswood, Rock Ferry, took the lead with capital blooms. For twelve double Dahlias Messrs. A. Dickson and Sons secured the chief position with excellent blooms. For twelve bunches of single varieties Mr. J. Jellico was placed first.

Bouquets.—The schedule only provided two classes for these, but the competition was good in both. The exhibits throughout were highly praiseworthy and far above the average; in fact, better have not been seen at any of the previous exhibitions held by the Society. For two bouquets in the open class Messrs. Perkins were well placed first with splendid examples, Mr. Cragg was an excellent second, and Mr. Geo. Cashel of the Liverpool Horticultural Society a good third. Orchid blooms were liberally used, and *Pancretiums* rendered the first two really charming. In the corresponding class Mr. Cragg was first, Mr. Blair second, and Mr. Todd, High Street, Woolton, third. For one vase or epergne for table decoration Mr. Cragg was easily first with a light arrangement.

FRUIT.—In a few instances the examples staged excelled those exhibited at any previous exhibition held by the Society. On the whole the exhibits were a little below the average of past years, but when the unfavourable season is taken into account the display was an excellent one. In the class for eight dishes, distinct kinds, not more than two varieties of Grapes, Mr. R. Dawes, gardener to the Hon. Mrs. Ingram, Leeds, was accorded the premier position with very good Madresfield Court and Muscat of Alexandria Grapes, a fair Queen Pine, Reading Hero Melon, Royal George Peaches, Lord Napier Nectarines, and remarkably fine Brown Turkey Figs. Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, was a good second, having fine Elruge Nectarines and Bellegarde Peaches. The Grapes were good in bunch and berry, but the Black Hamburgs were rather short of colour, and the Muscat of Alexandria scarcely ripe. Mr. J. Edmonds, gardener to the Duke of St. Albans, Bestwood Lodge, Notts, was third, having good Black Hamburg Grapes and Duke of Edinburgh Strawberries. In the corresponding class for six dishes, Pines excluded, Mr. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, Liverpool, was first with Madresfield Court and Muscat of Alexandria Grapes, the former being really fine in every respect, very large and highly coloured Bellegarde Peaches, Elruge Nectarines, and a good Melon, La Favourite, the weakest dish being Strawberry President. Mr. D. Lindsay, gardener to Sir T. E. Moss, Bart., Otterspool, was second, and had fine Muscat of Alexandria Grapes and Bellegarde Peaches. Third, Mr. J. Stoney, gardener to Sir Thomas Earle, Bart., Allerton Towers, Liverpool.

Pines were better than they have been for the past two or three years, and were staged in greater numbers. For two fruits, Mr. P. Blair, gardener to the Duke of Sutherland, Trentham, was first with good Queens; Mr. G. Walton, gardener to F. H. Sykes, Esq., Cringle House,

Cheadle, second; and Mr. W. Tunnington, gardener to Mrs. McIver, Calderstone, third. For one fruit, Mr. P. Blair was again first with the same variety as in the preceding class; Mr. J. Bennett, gardener to the Hon. C. H. Wynne, second; and Mr. Elsworthy third.

Grapes were not quite so good or shown in such large numbers as previously, although the successful competitors staged wonderful examples of Black Hamburg and Buckland Sweetwater. In the class for four bunches, distinct, Mr. G. Middleton, gardener to R. Pilkington, Esq., Rainford Hall, St. Helens, was deservedly first with good Muscat of Alexandria, Black Hamburg, Buckland Sweetwater, fine, and Madresfield Court, rather short of colour. Mr. J. Stevenson, gardener to W. W. Pilkington, Esq., The Hazels, Roby, was a good second, having very fine Black Hamburgs and Madresfield Court. Mr. T. Elsworthy secured the remaining award, the bunch of Buckland Sweetwater in this collection being remarkably fine in both size of bunch, berry, and colour; four collections were staged. For two bunches of Black Hamburg Mr. J. Stevenson was well ahead with perfectly finished examples. Mr. P. Barker, gardener to G. Raynes, Esq., Rock Ferry, followed with larger bunches, but scarcely so even, and they lacked colour slightly towards the points. Mr. R. Brownbill was the other successful competitor with good-sized bunches with large berries, but rather short of colour; eight collections were staged for the three prizes offered. For two bunches of Muscat of Alexandria there were five or six entries staged; Mr. G. Middleton took the lead with finely finished examples; being good in bunch and berry; Mr. J. Stoney was second with good bunches and the largest berries of any exhibited, but the bloom was very much damaged. Mr. W. Pratt was placed third with creditable examples scarcely ripe. For two bunches of black Grapes Mr. J. Bennett took the lead with Alnwick Seedling, large bunches superbly finished, but the berries were small. Mr. J. Stevenson was second with Madresfield Court, large bunches and berries of an enormous size, but short of colour. Mr. W. Wilson, gardener to H. Cunningham, Esq., was also successful with the same kind; five exhibitors staged in this class. For two bunches of white Grapes Mr. J. Bennett was again to the fore with grand Buckland Sweetwater; Mr. W. Oldham, gardener to J. Beecham, Esq., second with Duke of Edinburgh, scarcely ripe, but in other respects very fine; third, Mr. T. Elsworthy with the same kind as staged by the first-named exhibitor. Several of the exhibits of the remaining five competitors were also good.

Peaches.—A few dishes were above the average, but on the whole they were below both in quality and numbers. Only ten dishes were staged in the two classes devoted to this fruit. Mr. W. H. Divers, gardener to J. T. Hopwood, Esq., Ketton Hall, Stamford, took the lead with very fine Royal George, followed by Mr. J. Bennett, showing the same kind; and Mr. Dilworth, gardener to W. G. Holland, Esq., Liscard Vale, with good Bellegarde, but short of colour. In the corresponding class Mr. T. Elsworthy was first with Bellegarde shown in his usual style, Mr. J. Stoney second with Grosse Mignonne, and Mr. D. Lindsay third with the same kind as secured for the first prize. Only some twelve dishes of Nectarines were staged for the six prizes offered. Mr. J. Bennett took the lead with Pine Apple, followed by Mr. P. Blair with the same; while Mr. Eaton, gardener to J. Pilkington, Esq., Roby, was third with rather small fruit. Mr. T. Elsworthy was first in the corresponding class with large highly coloured fruits of Elruge; Mr. J. Hurst, gardener to W. B. Bowring, Esq., Beechwood, Aigburth, second with Pine Apple, and Mr. J. Barker third with the same.

Melons were above the average both in appearance and quality. Some seventeen fruits were staged in the two classes devoted to them. For one green-flesh Mr. W. H. Divers was first with a well-netted, handsome fruit of Ketton Gem that was pronounced to be of excellent flavour, as may be gathered from the fact that it beat Dickson's Exquisite, staged by Mr. J. Barker, and which gained the second award. Mr. Pratt was third with Longleat Perfection. For one scarlet-flesh Mr. R. Dawes secured the premier position with Scarlet Hybrid, Mr. G. Lyon, gardener to J. H. Kenion, Esq., Rock Ferry, second with Scarlet Premier, Mr. T. Moorhouse, gardener to B. Brocklehurst, Esq., Sandsfield Park, West Derby, third.

Hardy Fruits.—Considering the season these were good. For one dish of Strawberries five exhibitors entered. Mr. R. Dawes was first with large fruits of President, Mr. J. Lambert, gardener to Col. Wingfield, Onslow Hall, Shrewsbury, second with the same kind, and Mr. T. Winkworth third with Myatt's Prolific. For one dish of Cherries Mr. W. H. Divers was first with Bigarreau, Mr. R. Dawes second with Elton, and Mr. Lambert third. Nine dishes were staged. For a collection of six dishes, distinct, Mr. Hannagan, gardener to R. C. Naylor, Esq., Horlton Hall, was first with good dishes of Raspberries, Red Currants, Cherries, Strawberries, and Black Currants; second Mr. Ed. Gregg, Arrowbank, Birkenhead; and third, Mr. J. Stoney. For a basket of fruit tastefully arranged only three competitors exhibited. Mr. J. Stoney took the lead with the most tastefully arranged collection, Mr. T. Elsworthy was second with finer fruit but less tastefully arranged, and Mr. P. Blair third with a collection in a tray or box.

VEGETABLES.—These throughout were excellent, and the competition in every class was most spirited. Four collections were staged in the open class for twelve distinct kinds, and Mr. J. Lambert was well first with a grand lot, having very good Sulham Prize Celery, Snowball Turnips, Autumn Giant Cauliflower, Lyon Leeks, Globe Artichokes, Paragon Beet, Seville Longpod Beans, Cucumber Telegraph, Tomatoes, Prodigy Peas, Intermediate Carrots, and Chancellor Potatoes. Mr. J. Stoney was a good second, and Mr. H. Forder (gardener to Col. Cornwallis West, M.P., Ruthin Castle), third. In the corresponding class for

the same number of dishes, Mr. A. R. Cox was first; Mr. J. Stoney an excellent second; and Mr. J. Littlemore, 173, Welling Road, Aintree, third, five collections being staged. For six dishes, prizes given by Messrs. Sutton & Sons, Reading, Mr. J. Lambert was first, and staged Sutton's Seedling Potato good, New Red Intermediate Carrot, and Maincrop Marrowfat Pea. Second Mr. Stoney, good Sutton's Prizetaker Leeks, Tomatoes Perfection, the Carrot named above, and Prizetaker Potatoes. Third, Mr. J. Walton, gardener to F. Tobin, Esq., Old Hall. For six dishes of Peas Mr. J. Stevenson was first with Duke of Albany, Duke of Connaught, Telephone, the Duchess, Stratagem, and Telegraph. Second and third, Messrs. T. Winkworth and J. Lambert in the order named. For three dishes the winners were Mr. W. E. Owen (gardener to Sir Rd. Sutton, Combermere Abbey, Salop), Mr. W. H. Divers, and Mr. W. Hasker, Bromborough Pool, respectively. For two dishes Mr. P. Blair took the lead. Potatoes were excellent. For six dishes Mr. J. Lambert staged decidedly the finest examples, but at the time of taking our report no first had been awarded, owing to the Judges thinking that two of the dishes staged for round varieties were not so. Sutton's Seedling being one and Chiswick Favourite the other, but a long variety were staged for the latter. Mr. H. Forder was placed second with International Kidney, Veitch's Perfection, Snowdrop, Vear of Laleham, Sutton's Thirty-six, and Adirondack. Third, Mr. T. Winkworth. Six collections were staged. For four dishes five collections were staged. Mr. J. Lyon, Fir Grove Cottage, Whiston, was first with The Dean, International Kidney, Snowdrop, and Early Regent; Mr. B. Cromwell second, and Mr. W. Hasker third. For two dishes, Mr. J. Bennett took the lead, followed by Mr. W. Bustard and Mr. E. Gregg. For three dishes of Tomatoes some splendid dishes were staged amongst the four collections. Mr. G. Lyon was first with grand Hackwood Park, Trophy, and Harefield Golden Gem. Second, Mr. W. Ireland, Prospect Vale, Wallasey; and third Mr. W. Morris, gardener to H. Tyrer, Esq., Aintree. For one dish Mr. R. Dawes took the lead with Jubilee; Mr. W. Ireland followed with Perfection, and Mr. J. Edmonds third. Eight brace of Cucumbers were staged. Mr. J. Stevenson was first with grand fruits of Prescott Wonder, Mr. W. E. Owen and Mr. J. Elsworth second and third in the order named.

Tomatoes in pots were not so good as they were last year, although they were creditable for the season. Mr. J. Stoney was again successful this year, and although confined this season to one plant in a pot he had allowed his to form three leads from just above the surface of the soil. Mr. J. Jenkins was second, and Mr. J. Fell, gardener to Mrs. J. Campbell, Mersey Road, third.

MISCELLANEOUS EXHIBITS.—These were numerous. Messrs. W. & J. Birkenhead, Sale, Manchester, contributed two groups of hardy and exotic Ferns, young clean healthy plants. Messrs. R. P. Ker and Sons, Aigburth Nursery, an excellent table of stove foliage plants and Ferns, which included highly coloured Crotons and most of the noteworthy plants of recent introduction. Conspicuous was *Dracæna lineata* variegata, or as it is named, Droucetti, a narrow-leafed variety with a white margin; *Croton Aigburth Gem*, a hybrid between *C. Neumannii* and *Rodeckianus*, for which a first-class certificate was awarded. This variety has narrow leaves and much of the character of the last named parent, with some of the rich colouring of *Neumannii*, which was also raised by Mr. Ranger in the Aigburth Nurseries. Messrs. Dicksons, Limited, Chester, contributed a very handsome collection of similar plants, amongst them *Begonias* were freely intermixed. The Liverpool Horticultural Company, Garston, had a similar group, and two splendid circular groups of Tea Roses. Messrs. Cannell & Sons, Swanley, sent boxes of double and single Tuberous *Begonias*, which were very striking, having travelled well; also six plants of *Begonia Octavie* with its pearly white double flowers, for which a first-class certificate was awarded. Mr. G. Downes, Lodge Lane, sent pans and pots of Ferns suitable for various forms of decoration. Mr. E. G. Reid, 34, Pelham Grove, Sefton Park, exhibited his prize plan for the new public park at Ramsay and others, as well as drawings of Orchid flowers. In October this enterprising landscape gardener anticipates starting a class for gardeners and under gardeners to teach drawing three hours weekly, for the modest sum of 5s. quarterly.

Implements were few in number, Mr. P. B. Harkin, Dulton Street, exhibited samples of Bamboo canes of suitable sizes for all purposes, Orchid baskets, and his ornamental teak tubs. Mr. Jos. Bramham showed his Allerton Priory boiler; Mr. J. Webster, Wavertee, a small span-roofed greenhouse; Messrs. F. & J. Mee boilers, &c.

Never since the Society started have the varied arrangements been better carried out, which is highly creditable to all who have taken an active part in its management. The Society will to some extent be re-organised, we understand, and we hope that the success which it deserves will again attend the exertions of the horticulturists of Liverpool.

SOUTHAMPTON SHOW.

AUGUST 4TH AND 6TH.

ANOTHER most successful show must be chronicled for the Royal Horticultural Society of Southampton, which was held as usual in the beautiful grounds of the Society in Westwood Park. The Exhibition in question must rank as one of the best yet held by this Society; competition was in all cases most spirited, and the results very satisfactory. The arrangements were similar to other years, the plants and groups occupying two immense tents, which were connected so that a view could be obtained of the whole at once. A separate tent was set apart for table decorations, bouquets, &c., while another very large one was devoted to fruit, cut flowers, and vegetables. The arrangements

reflected much credit upon the Committee, of whom Captain Gibbs is Chairman. The indefatigable Secretary, Mr. C. S. Fuidge, was as usual in his place, and therefore the whole went smoothly, as it always does when he is at the helm. The Committee, Judges, and principal exhibitors lunched together in a marquee on the ground, the Mayor (Mr. H. Coles) in the regrettable absence of the President, W. H. Myers, Esq., occupied the chair.

PLANTS.—These were shown in larger numbers than usual, the general good quality being maintained throughout, while the competition was keen. The great class in which the most interest was displayed was for twelve stove or greenhouse specimens, six to be in bloom, and six foliage, distinct, for which the handsome prizes of £18, £15, £12 were offered. Four competitors entered their exhibits, making an imposing display, being staged as they were up one side of the large tent. The premier award was given to Mr. J. Cypher, Cheltenham, by the weight of his flowering plants, although the second prizewinner, Mr. Lock, gardener to W. B. Cleave, Esq., Newcombe House, Crediton, had the best foliage plants, *Latania borbonica*, not extra large, but perfect; *Kentia Fosteriana*, very fine; and *Croton Queen Victoria*, good, were his best foliage specimens. Especially good was *Erica Parmenteriana rosea*, *E. ferruginea major*, fresh and freely flowered; *Allamanda nobilis*, and *Kalosanthes coccinea*. Mr. Lock had *Latania borbonica* of huge size, magnificently grown and coloured; *Croton Warreni* and *Williamsi*, the former a perfect fountain of colour; *Erica amula* and *Stephanotis floribunda*, both freely flowered. Mr. E. Wills, gardener to Mrs. Pearce, The Firs, Bassett, Southampton, was awarded third honours for most creditable plants. For the same number of plants, under the same conditions as to variety, but open to gardeners only, £10, £7, £5, were offered. Here Mr. J. Amy, gardener to the Hon. Mrs. Elliott Yorke, Netley Cliffe, Southampton, succeeded in winning first honours with a capital dozen, including *Cycas revoluta*, a perfect plant in every way; *Latania borbonica*, *Allamanda Hendersoni*, 6 feet in diameter, magnificently flowered; *Bougainvillea glabra*, and *Rhyncospermum*, very large. Mr. N. Blandford, gardener to Mrs. Haselfoot, Moorhill, Bitterne, was a good second. *Allamanda Hendersoni* was grand, *Bougainvillea glabra* fresh, and a good specimen of *Lasiandra macrantha floribunda* were his best. Mr. J. Curry, gardener to Lieut.-Col. Pepper, Salisbury, was third. Six stove and greenhouse plants in bloom, distinct, open class, £5 was the first prize, which Mr. Wills succeeded in obtaining. Second Mr. H. James, nurseryman, Norwood. Third Mr. Blandford. For the same number of foliage plants Mr. Lock was first; *Crotons Disraeli* and *Johannis* were magnificent in colour. Second Mr. Wills, *Phoenix reclinata* being the best. Yet another class for nine miscellaneous plants was provided, £6 being the first prize, which fell to Mr. Molyneux, who had excellent specimens of *Latania borbonica*, *Croton Queen Victoria*, and a good plant of *Trachelium cœruleum*. Mr. W. Thompson, gardener to Captain Bolland, Blighmount, Millbrook, was second.

For a miscellaneous group arranged for effect, occupying a space of 120 square feet, Mr. Wills was easily first with a bright lightly arranged group, the foliage and flowering plants being evenly balanced. Graceful Palms were at the back, while a base of Maidenhair Ferns occupied the middle and front, from which rose *Dracænas*, *Crotons*, *Orchids*, *Heaths*, *Celosias*, *Hydrangeas*, and *Gloxinias*. Mr. J. James was second, his group showing too much green foliage and not enough of colour. Mr. J. Amy was third. For a collection of Orchids there was only one entry, but this produced a capital effect at one end of the tent. Not large but healthy plants were they, coming from Mr. T. Osborne, gardener to J. J. Buchan, Esq., Southampton, the most noteworthy plants being *Cypripedium bellatulum*, *Oncidium Lanceanum*, *O. Jonesianum* quite happy-looking growing on a tile, *Cœlogyne Massangeanum*, *Cattleya Dowiana*, *Cypripedium Veitchii*, and *Cattleya Schofieldiana*. Mr. Osborne was also first for a single specimen Orchid with *Dendrobium Dearii*, three spikes. Mr. Wills second with *Calanthe veratrifolia*. For six specimen *Crotons*, distinct, Mr. Lock was easily first with plants all well coloured. Mr. Wills second with a poor lot. *Begonias*, single and double, were well shown, Mr. Blandford being first in the former class, while Mr. G. Bushby was first for the latter, as he was also with four Zonal or Nosegay *Pelargoniums*; six *Coleus* with beautiful pyramids, four *Fuchsias*, and for six *Selaginellas*. Messrs. Oakley & Watling, nurserymen, Bevois Mount, Southampton, staged the best miscellaneous collection of nursery stock; second Mrs. Kingsbury, Bevois Mount, Southampton. Mr. Osborne had the best six *Achimenes*; for six *Fuchsias*, and single specimen also, freely flowered they were and 7 feet high; six *Cockseombs*; for one specimen plant in flower with *Cypripedium Sedeni* with twenty spikes; and for six *Gloxinias*, stout and erect were the flowers. With a capital plant of *Croton Chelsoni* Mr. Lock took first prize for a single specimen foliage plant, and for six hardy Ferns; while the first honours for six exotic Ferns fell to Mr. Wills with healthy large plants of *Davallia Mooreana*, *Microlepia hirta cristata*, *Nephrolepis davallioides furcans*, and *Davallia polyantha*. Mr. J. R. West, gardener to J. R. Wigram, Esq., Northlands, Salisbury, had the best *Celosias*, naturally trained freely flowered specimens. In a brisk competition for six table plants Mr. Molyneux led the way with even neat suitable plants; Messrs. Wills, C. J. Waite, and Amy following in the order named. Amateurs' groups, vegetables, and cut flowers were capital.

FRUIT.—Although not so abundant as in some past years, the general quality was good throughout, the competition being keen. The white Grapes, as is generally the case this season, showed a want of colour; black Grapes in some instances indicated the effects of the

recent bad weather, although some were very fine. There was a good show of Melons, but in a few instances only were they of high flavour. Peaches and Nectarines were good, being highly coloured, if not large. Hardy fruits were well shown. For six dishes of fruit, the varieties to be distinct (Pines excluded), four prizes were offered, the handsome sum of five guineas being the first, which brought five competitors. Mr. H. W. Ward, gardener to the Right Hon. Earl of Radnor, Longford Castle, Salisbury, was easily first—Muscat of Alexandria, shapely bunches with good berries and good colour; Black Hamburgh, medium sized bunches of good colour; fine Hero of Lookinge Melon; large Goshawk Peaches; rather green Pine Apple Nectarines and Brown Turkey Figs were his dishes. Mr. W. Allen, gardener to Sir G. Russell, Bart., M.P., Swallowfield Park, Reading, was second, having good Black Hamburgh Grapes and Melon, with well coloured Violette Hâtive Peaches and Lord Napier Nectarines. Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, was third, Madresfield Court, Buckland Sweetwater, and Pine Apple Nectarines were his best dishes. Mr. J. Evans, gardener to Lady L. Ashburton, Melchet Court, Romsey, being fourth. Five competed with three bunches of black Grapes, the best coming from Mr. C. Warden, gardener to Sir F. Bathurst, Clarendon Park, Salisbury, who staged good sized clusters, even berries, and well finished. Second, Mr. W. Allen, whose bunches were rather loose, with fine berries and good colour. Third, Mr. C. Curtis, gardener to J. S. Dixon, Esq., Hollybank, Hythe, with large bunches and berries, but not well coloured. For three bunches of white Grapes, Mr. E. Molyneux was the only competitor, staging good Buckland Sweetwater. For two bunches of black Grapes Mr. E. Molyneux was an easy first with Madresfield Court, only wanting a trifle more colour to make them perfect. Mr. W. Sanders, gardener to J. East, Esq., Longstock House, Stockbridge, was second. For the same number of white bunches Mr. C. Curtis led the way with large Foster's Seedling, moderately coloured. Mr. J. Allen, gardener to Captain the Hon. V. Montague, Wherwell Priory, Andover, was second. The best single bunch of black Grapes came from Mr. C. Molyneux, who again staged Madresfield Court of capital quality; Mr. J. Evans being second with Black Hamburgh, fine in bunch, berry, and colour; Mr. Warden was third. Mr. C. Curtis, with Foster's Seedling, and Mr. J. Allen, with Muscat of Alexandria, took the honours as placed for one bunch of white Grapes. For one Pine Apple, Mr. G. Lock, gardener to W. B. Cleave, Esq., Newcombe House, Crediton, was first with Smooth Cayenne of good size, Mr. Ward following with a fair Queen. The best scarlet flesh Melon came from Mr. J. Evans, a small Read's Hybrid, with Turner's Scarlet Gem; Messrs. W. & G. Drover, nurserymen, Fareham, was second. Seven competed with one green flesh Melon, Hero of Lookinge from Mr. Ward taking first honours; Mr. W. Sanders being second with the same variety. Mr. G. Garner, gardener to Mrs. Bradyll, Amberwood, Christchurch, third. For one dish of six Peaches nine staged. Mr. C. Curtis was first with Royal George, richly coloured; Mr. J. Allen, second, with large Late Admirable. For one dish of six Nectarines ten staged, Mr. G. Inglefield, gardener to Sir J. W. Kelk, Bart., Tedworth, Marlborough, with Elruge, beautifully coloured, but small; Mr. Molyneux, second, with Pine Apple; Mr. C. Curtis third. For six dishes of fruit, outdoor growth, distinct, Mr. J. Evans led the way with Gooseberries, Red Currants, and Strawberries, all fine; Mr. R. West, gardener to J. R. Wigram, Esq., Northlands, Salisbury, was a close second; third, Mr. W. Sanders.

VEGETABLES.—The competition in all classes was keen, and the produce staged was of remarkable excellence. For twelve distinct varieties, two kinds of Potatoes allowed, round and kidney, seven competed. Mr. C. J. Waite, gardener to Col the Hon. W. P. Talbot, Glenhurst, Esher, was first, staging in his usual style, his best dishes being Webb's Giant White Tripoli Onion, Webb's new Kinver Cauliflower, new Intermediate Carrot, long and clean, Webb's Stourbridge Glory Potato, a long variety of good shape; Reading Perfection Tomato, extra good, and Ne Plus Ultra Scarlet Runner Bean, fine dish. Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, was a close second; Early Puritan Kidney Potato, clean and good; the Duchess Pea, of fine colour, extra large; Standard Bearer Celery, and Tomatoes were his best dishes. Mr. T. Wilkins, gardener to Lady Theodora Guest, Inwood House, Hurstbridge, Blandford, was third with smaller produce, but neat and good. For nine varieties eight competed. Mr. F. J. Cox, gardener to R. K. Wyndham, Esq., Corhampton House, Bishops Waltham, led the way with the Turner Hybrid Tomato, Duke of Albany Pea, and White Elephant Onion, all of first quality. Mr. Molyneux followed closely, and Mr. J. Allen third. For six varieties, the prizes offered by Messrs. Webb & Sons, there were eight entries, Mr. C. J. Waite being again first, his exhibits being similar to those in the larger class; Mr. Pope and Mr. T. Wilkins being second and third. For the best nine specimens of Sutton's Reading Perfection Tomato, the prizes being offered by this firm, seven competed, Mr. C. J. Waite securing first honours with large, even, well ripened fruits, Mr. T. Annals, gardener to T. J. Shenton, Esq., The Glen, Golden Common, Winchester, being second, Mr. G. Inglefield being third. For one dish of Tomatoes Mr. W. Joy, nurseryman, Shirley, staged splendid Hackwood Park, and was easily first. Mr. Waite and Mr. Cox followed in the order named among twelve entries. For four sorts of round and four sorts of kidney Potatoes, six of each, nine competed. Mr. R. West was first with tubers of capital quality, being clean, of even size, Mr. Bresee, Sutton's Seedling, and Chancellor being the best. Mr. W. Sanders followed close, Mr. H. W. Ward being third, he also staging good quality.

CUT FLOWERS.—For the most elegantly dressed table with flowers suitable for six persons, five competed. Mr. G. Lock was awarded first honours with a well arranged table, three epergnes gracefully yet not heavily filled with appropriate flowers, amongst which were intermixed long, narrow, gold-coloured Croton leaves hanging from the summit of each stand, which produced a decided effect, the specimen glasses being lightly filled with Stanhopeas and Anthuriums, and Ferns. Second, Miss Flight, Cornstiles, Twyford, Winchester, the base of her centre epergne being rather too heavy, while the placing of the purple Beech leaves on the cloth around the epergne added still more to its heavy appearance; the four corners of the table were also rather crowded. Third, Miss Stratton. The best decorated epergne was from Mr. J. Cypher, nurseryman, Cheltenham, with a splendid arrangement, the base particularly so, and the flowers of the choicest, *Francoa ramosa* and the foliage, long and drooping, of *Russelia juncea*, being effectively used along with Orchids and other choice flowers. Mr. J. R. Chard, nurseryman, Stoke Newington, and Miss B. Flight being second and third respectively. The most tastefully arranged basket of flowers, open only to ladies, Miss B. Flight led the way with a choice arrangement, followed by Miss Hobby, Freemantle. The same two competitors were placed in the same order for a basket of wild flowers and grasses, the first prize one being charmingly arranged as to colour. For the most elegant ball bouquet Mr. J. R. Chard was first with a rich arrangement, of Orchids principally, Messrs. Perkins & Sons, Coventry, being second. The latter reversed their position for one bridal bouquet with a splendid arrangement, Mr. Chard being second for one not so light in arrangement. For six buttonhole bouquets Messrs. Perkins again took first with extremely neat and choice arrangements, principally Orchids, Mr. Chard being second. For twelve bunches of cut flowers, distinct, Mr. Evans was first with a choice collection, followed by Mr. H. James, nurseryman, West Norwood. For twelve varieties of hardy herbaceous cut flowers, Mr. Molyneux was an easy first with a splendid box, chief amongst them being Phlox Max Kolb, *Rudbeckia laevigata*, *Trachelium caeruleum*, *Lychnis Flos-Jovis*; Mr. B. Ladhams, florist, Shirley, and Messrs. J. Cheal & Sons, nurserymen, Crawley, Sussex, being second and third respectively. The best double and single Pelargoniums were staged by Mr. G. Busby, gardener to F. Willan, Esq., Thornhill Park, Bitterne. For twenty-four blooms of Roses, distinct, Messrs. Keynes, Williams and Co., The Nurseries, Salisbury, was first with flowers full and rich in colour, Beauty of Waltham, Alfred Colomb, Charles Lefebvre, and Marshal P. Wilder being most noteworthy, Messrs. Perkins & Sons being second. For twelve blooms of Roses, distinct, gardeners only, Mr. W. Clements, gardener to H. J. Gibbs, Esq., Foord, near Salisbury, and Mr. W. Neville, gardener to F. W. Flight, Esq., were first and second respectively. The best Carnations and Picotees, twelve of each, were staged by Mr. J. Ribbeck, 5, Bevois Terrace, Southampton.

The following exhibits were staged not for competition:—A double crimson Begonia from Mr. Wills, which received a first-class certificate, compact in growth, with full solid blooms. Two boxes of Roses from Messrs. Keynes, Williams & Co. Messrs. Cheal & Sons, Crawley, Sussex, had two boxes of Pompon and single Dahlias of good appearance. The new seedling Potato Webber's Early White Beauty, which has already received a first-class certificate from the Royal Horticultural Society, as its appearance merited (it is said to be of excellent quality and very early), was shown by Mr. F. Webber, Tonbridge. Messrs. Cannell and Sons, Swanley, obtained a certificate of merit for cut blooms of double and single Begonias, also several plants of a very fine double white Begonia Octavia, a full Camellia-flowered kind of excellent quality. Messrs. Lucombe, Pince & Co. staged fine Carnations and Picotees, also forty-eight blooms of Rose Niphetos. Mr. Rogers, Red Lodge Nursery, had a capital collection of 150 plants, representing the best of his collection of hardy shrubs, arranged effectively at one end of the tents. The effect was good.

KITCHEN GARDEN.

SOWING AUTUMN ONIONS.—All who take an interest in Onions know the Giant Rocca and Tripoli types, seed of which is sown in autumn to afford bulbs in spring and early summer. They are most useful at that time and for exhibition purposes. On or about the 12th of August is our date for sowing the seed. We have tried it both before and after that date, but never found any answer so well as the 12th, as the plants become a good size before the winter, and very few "bolted" in spring. The latter is important, as we have known whole beds of autumn-sown Onions run to flower in April and May and never bulb. The soil for these Onions should be well manured and fully exposed to the sun. To prevent worms or grubs doing damage sprinkle a good quantity of salt in with the manure before digging, and if the soil is so dry that it will not stick to the feet tread the surface very firm after digging, but before sowing the seed broadcast or in rows. If in the latter sow 10 inches apart, and in all cases cover with soil to the depth of 1 inch, as it keeps the plants firm at the collar throughout the

winter. Apart from these Onions furnishing good bulbs in spring they also supply useful green ones for salad from November onwards, and where they are much used in this way a large quantity should be sown.

ONIONS BULBING.—The present is a poor season for Onions bulbing. We have never known them so backward. Some years ago we had spring Onion bulbs measuring 11 inches round on July 20th. At the present time we should have difficulty in finding any to measure 6 inches round, and judging from the spring Onions we have lately seen at shows this deficiency is general. We must not think of harvesting the spring Onions this year in August, but it may be necessary to allow them to grow until the end of September before they are large and matured. The latter condition is important. Where the stems are strong and upright twist them over a little to expose the bulbs to the sun. The bulbs of the Onions sown last autumn, especially Trebons, are very fine now. We have them 20 ozs. in weight, with no signs of splitting; but where they are going in this way the whole should be drawn and laid in the sun to dry. Do not lay them on the soil or a wet spot, but place them on a dry base, such as a walk.

CUCUMBERS IN FRAMES AND IN THE OPEN.—Open-air Cueumbers are not the success now they were last year; fruits are few and long in swelling, and in some instances they have failed altogether. Plants in frames have also been slow in bearing of late. The heat is gone from the manure beds, the sun has not been sufficiently powerful to forward them, and if immediate attention is not given them there may be a blank in the Cueumber supply. In any case frame Cueumbers should have extra attention, and if the old shoots are removed from the plants, a little surface dressing applied to the roots, and a good lining of fermenting material round the frame, there will be abundance of autumn Cueumbers in spite of the weather.

MATERIAL FOR MUSHROOM BEDS.—To have Mushrooms from November onwards the first bed should be formed in September, and material should be collected forthwith. Horse droppings are the best of all. If there are only one or two horses it will take a fortnight or three weeks to get sufficient. The manure should be put under cover in an open shed daily to keep it from rain, and turn it over daily to dry and sweeten it before making up the bed.

WINTER SPINACH.—There is no more useful vegetable in the garden in winter than Spinach. When a good plantation of it is well up and in abundant leaf by November it may be gathered from almost daily throughout the winter, and professional cooks can use it in such a variety of ways that it is never tiring. Fork a piece of ground from which Peas, Potatoes, or any crop has been cleared, open drills 15 inches apart and 1½ inch deep, and sow the seed rather thin, as it germinates so freely as a rule that thick sowing is a mistake.

LEEKs.—These may well be classed amongst the most useful of all winter vegetables. They will bear any amount of severe weather. Nothing in the way of cold or bad weather will injure them, and they are in season from November until May. Cooked and served like Asparagus they are really delicious. Early Leeks for shows are very well, but it is the main crop for the kitchen that is the most important, and it is not yet too late to plant a quarter for winter and spring use, but planting should not be delayed any longer.

GREENS GOING BLIND.—We notice many Savoys and Broccoli are losing their centres this season. It happens with us every year, but in some seasons is worse than others. This is a bad one, and unless cultivators examine their quarters and fill up the deficiencies with good plants the autumn may come and find them with plants well furnished with outer leaves, but minus the important centre. We have gone through this experience, but avoid it always now. We have also noticed plants are more apt to go blind in July than afterwards, and if all plantations are made good at once they may not require further attention.

PEAS.—Midseason varieties have furnished a long succession of pods this year. They did not fill very rapidly, but the abundance of moisture at the roots has kept them going. There is no object in keeping them, however, when once the crop has been gathered, and immediately this has been secured clear them away and fill up the ground with other crops. Save the best of the stakes, and as late Peas require extra support some of the stakes drawn up now should be put to them.

FRUIT FORCING.

FIGs.—*Early Forced Trees.*—The second crop is ripening fast, and watering at the roots must be diminished and syringing discontinued. As soon as the fruits are all gathered the trees may have a good washing with the syringe or garden engine to free the foliage from red spider, otherwise a circulation of dry warm air should be maintained in the house until the foliage begins to fall naturally. If the trees are infested with scale they may be syringed with soapsuds, adding a wineglassful of petroleum to every four gallons, kept thoroughly mixed whilst being applied with a syringe by stirring briskly with a broom handle or alternate squirts of the syringe into the vessel.

The earliest forced trees in pots may be placed out of doors in a sunny position, allowing them sufficient water. They must not, however, be placed outdoors until the wood is well matured. If the wood is unripe let them remain under glass, keeping them rather warm by day with moderate ventilation, and throw the ventilators open at night. Exposure to the atmosphere after the wood is sufficiently mature will harden it, which is of great importance, especially to Figs. Young trees in pots from cuttings in the spring, and which are intended for fruiting in the second or third year of their growth, must still be attended to in pinching off the tops of strong shoots to form the foundation of a symmetrical head in their first year's training.

VINES.—*Midseason Houses.*—The heavy rains, low temperature, and sunless weather have been against Grapes acquiring bloom and colour rapidly, but they have swelled well and are larger in berry than usual. A low night temperature, or 60° to 65°, will assist Vines carrying heavy crops, by giving them rest in the colouring process and in gaining bloom, it being accompanied by moderate ventilation, allowing a steady rise by day with abundance of air.

Muscats in the last stage of ripening will need fire heat to keep up a day temperature of 75° to 80°, 85° or 90° from sun heat, and 65° to 75° at night; light being essential to their fine amber colour, it may be desirable to stop the laterals somewhat closely. If the weather be very bright it may be advisable to draw a double thickness of herring-nets to break the fierce rays of the sun, and so prevent excessive evaporation, which is neither good for the foliage nor the Grapes. Make sure that there is no deficiency of moisture in borders, giving if necessary a thorough soaking in the early part of a prospective fine day.

Late Houses.—For such varieties as Lady Downe's and Muscats, which are liable to be scalded and have not completed stoning, a rather dry and warm atmosphere must be maintained through the night, with free ventilation by day. Inside borders must be attended to, and when necessary have copious supplies of water; and where the Vines are carrying a full crop of Grapes some stimulant, as a fertiliser of some approved kind, sprinkled over the border and well washed in, will be of advantage. Keep the laterals regularly stopped, not allowing them to be made to the crowding of the principal foliage, or in such quantity that they must be removed in great bulk at one time.

Ripe Grapes are keeping colour well, but in bright weather afford shade from powerful sun. Gentle fires will be necessary to admit of a free circulation of air, and if the wet weather continue outside borders should be covered with some material, spare lights being preferable.

Vines in Pots.—The canes of those intended for early forcing should be in the last stage of ripening, but if by reason of the cold sunless weather they are not ripening freely, fire heat may be applied, maintaining good ventilation, and supplying no more water than is needed to secure the proper maturation of the buds that are to afford fruit. Any Vines that have the wood thoroughly ripe may be placed in the open air against the south aspect of a wall or fence, to which the canes can be secured to prevent damage by winds. The roots must be protected from heavy rains either by laying the pots on their sides or some other means must be employed. Although all lateral growths are to be checked the old foliage must not be removed, but allowed to fall naturally.

Early Forced Vines.—These will have the wood thoroughly ripe, and should, the old foliage being retained, have the laterals cut away and some of the long shoots shortened, deferring the final pruning until the foliage is nearly gone. If, however, the old foliage is partly lost allow some lateral growths to remain to appropriate the sap, and so keep it from starting the buds relied on for furnishing next year's crop. Remove the old mulching and surface soil and fork it from amongst the roots, taking the advantage of raising any that are deep and laying them in fresh material nearer the surface, supplying good loam, with which has been incorporated about a fifteenth of crushed bones and wood ashes. The uppermost roots ought not to be covered with more than 2 or 3 inches of soil, and a moderate watering being given they will push into the new soil freely, whilst there is yet foliage upon the Vines, which will enable them to break strongly and give a good account of the manurial matter furnished in liquid form or from water passing through mulchings of rich lumpy material. When partial renovation or lifting is deferred until the leaves fall the start is not nearly so satisfactory as when performed whilst there is foliage on the Vines. Where the Vines are enfeebled by continuous early forcing and it exerts a deteriorating influence through their having to make their growth and perfect the crop under disadvantageous circumstances, continuous early forcing being a great strain on the energies of the Vines, it is most desirable to ease them occasionally (about every seven years) by a year's rest, during which they should be allowed to make rather more growth, every encouragement being given to a thorough recuperation both of the roots and Vines, if necessary thinning the old spurs or rods, and encouraging others in their place, whether it be shoots for spur pruning or canes for long pruning, as young parts allow of a freer access of sap, and the Vines consequently are regenerated by new parts supplanting, very much better and quicker results being effected by the process of partial lifting and a year's rest than making fresh borders and planting young Vines. The only thing important is to allow the young growths plenty of light, so as to insure thoroughly solidified wood and plump well-developed buds.

PLANT HOUSES.

Cinerarias.—Place these into larger pots as they need root room until they are in those in which they are intended to flower. Give the plants plenty of space, so that their foliage can develop naturally instead of being drawn up weakly. Plants that are crowded during the earlier stages of their growth are certain to lose their lower leaves by the time the flower spikes are advanced. This can be prevented by standing the plants from the first sufficiently far apart, so that light and air can freely penetrate amongst them. These are often grown too soft by keeping the frames close and overshadowing them. Large quantities will now be ready for placing into 6-inch pots, a very suitable size in which to flower dwarf strains; in fact, they are more useful for decoration in this than in larger pots. If a few large plants are desired they must be potted from the first without checking them. It is a mistake to allow the pots to become too full of roots before transferring the plants into others, whether required for large or moderate sized specimens. Later

plants may be lifted from boxes and placed into 60's. Those still in seed pans may be transplanted into boxes 2 inches apart. A fair percentage of leaf mould may be used amongst the compost in the early stages of the plant's growth. When in their largest pots good fibry loam should form fully three parts of the compost, the remaining part being composed of sand, leaf mould, and decayed manure.

Calceolarias.—Where these plants are appreciated as late in the season as it is possible to have them a little more seed may be sown. The earliest will be large enough for pricking out singly into pans or boxes. These may be placed about 1 inch apart, and when they have filled this space they can either be potted singly or placed into boxes until they are large enough for 3 or 4-inch pots. They do equally as well subjected to this treatment as when they are placed in small pots to start with.

Celosias.—Place the earliest plants into 5-inch pots and supply each one with a stake. Keep them close for a few days until they are rooting in the new soil, and then give them plenty of air to insure firm sturdy growth. Any plants in a rather backward state may be pushed on gently, but be careful not to draw them up weakly, or they will be liable to damp off just above the soil.

Mignonette.—Standards intended for winter and spring flowering should be placed, if not already done, in their flowering pots without delay. Train the plants on their trellises at the same time, and encourage them to make strong growths by admitting abundance of air to them. Remove the flowers as they appear, and dispose the shoots as they are made evenly over the trellis. Sow seed in 6-inch pots. Place the pots in cold frames and shade until germination has taken place, then admit air liberally.

Hydrangeas.—Take good cuttings from outdoor plants and root them at once. If taken where the wood is soft they will root quickly under handlights in any warm house where they are shaded from the sun. In making the cuttings it does not matter about cutting them to a joint, for they root just as freely from the stem. Directly they are rooted place them in cold frames for a few days to harden, and then fully expose them to light and air.

Violets.—Those intended for pots and frames are growing rapidly, as the past weather has been favourable for them. Remove all runners that the plants may form, and if dry weather sets in soak the soil with water and syringe freely to keep them free from spider. When attacked by this pest syringe the plants with a weak solution of sulphur.

Early-flowering Bulbs.—Roman Hyacinths, Paper White and double Roman Narcissus can now be obtained. The former may be placed thickly together in 5-inch pots, and the two latter in 1 inch larger, unless required solely for cutting in large quantities. With this object the bulbs should be placed in boxes. If the soil is in a suitable state for moisture no water will be needed before they are buried in ashes or other similar material outside.

THE BEE-KEEPER.

GENERAL MANAGEMENT OF BEES.

It was stated recently in a contemporary that it was advisable to lessen the size of the brood nest on the commencement of the flow of honey, as the bees would after this manipulation store more honey in supers. This advice is contrary to what is sought by most apiarians, and hinders the bees from storing much surplus honey, while it is sure to bring about swarming; in fact I used to practise this system to induce it, and scarcely ever failed. Much has been written on the advantage of having empty combs for obtaining a large harvest of honey, and I have explained how and when they should be made and used on the top of a hive to advantage. Instead of reducing the size of the body of the hive at the commencement of the honey flow, it ought to be enlarged if an extra harvest is desired. The Stewarton system again comes to our aid, and what we have practised for long is to give an extra under box filled with fresh combs or full sheets of foundation, then, if the honey is plentiful, large gatherings are made. If any bee-keeper has not tried this plan, let him do so, and compare the results of the two systems. The former prevents swarming where all is normal, and gives the bees great resources for ready storage, and if there is any truth or advantage in the saying, "that bees have first to store their honey below then carry it aloft before it is honey proper," then this system gives it, but I do not believe it, neither do I know any more than any other bee-keeper when the honey flow will commence. But I believe firmly that the nearer the bees are to the field of labour the greater will be the ingathering. Only one mile from my bees is a bee-keeper who works his bees as

I do, and similar hives, only he is close to many Plane trees, has this year already taken 42 lbs. of surplus honey from each stock. While there they appear to have gathered little more than what will be required for their own use, and filled supers with combs and some honey which will have to be fed back, as I seldom get supers pure enough if longer in being filled than a fortnight. Unless in very fine weather, all my hives have excessive numbers of bees, which at the end of the season will be of no use to me, as nuclei will take their place shortly, but for the untoward weather would all have been formed, whereas I have only a third of what is required yet.

All my present stocks will go to people in want of bees; but for them what other use could I put the bees to than the brimstone pit, a more merciful and profitable way of disposing of them than allowing stocks to die through bad management. Perhaps after everybody has learned the simple art of bee-keeping the problem will be solved how best to dispose of surplus bees and some use found for them. There is no one more against the practice of sulphuring bees than I am, but I do not, like many, attribute my success to keeping surplus bees in autumn, however much I advise those to do so who have an early but short honey season.

QUEEN REARING.

What ought to have been done in May and June will this year have to be performed in August and September, when if a few fine days occur, will serve our purpose for next year better than if the season had allowed us to finish that work earlier, as the queens with youth on their side will perform their work more satisfactorily for us next year, and lessen the surplus bees to be given away or destroyed. When our breeding queens are kept in one of the "best hives," it is an easy matter to exchange a frame of brood, even although supers are on, and give it to a queenless stock, which after ten days or less is divided into nuclei, each box having four shallow frames. After these are nursed for some time, I either tier or put them into a full-sized divisional box, placing it on a box or feeding-back stand where all the odd pieces of honeycomb are put for them to clean out. As the bees increase, I either give an additional box with comb foundation, or select the finest combs from my "condemned stocks" and build up all my nuclei with them, extracting the honey from the purest only, while the drone comb is melted down along with the rest after all the honey has been extracted by steeping it in water for mead-making, as a superior mead is obtained than from pure honey. After all this work is performed, by the end of September or the beginning of October, the hives are all levelled, and thoroughly covered and protected from wind and water, not to be disturbed again until the bees are crowding the hive, when they may either swarm, or I give them supers, as is most suitable, according to the season, always putting the empty one uppermost, unless when small supers are employed. Then I put the four empties two above each other at the coldest part, while nearly completed ones take that place on the top that the bees were finishing first and quickest. Suspended sections are easily managed, and full ones are removed while empty ones take their place. I doubt not but after a short time these sections will be in more repute, as they are in accordance with rational bee-keeping.

"The Best Hive" will be described, and instructions given how to make it in an early number, so that any amateur with but few tools can make them for himself. With some slight alterations it is now greatly improved on the first ones sent out, while it retains all the properties of the simple tiering hive, and can in that way be moved about from place to place in its single yet simple and perfect form.—A LANARKSHIRE BEE-KEEPER.

"A LANARKSHIRE BEE-KEEPER'S" HIVE.—I wrote several weeks ago stating I was anxious to obtain the cheap hive so highly spoken of by "A Lanarkshire Bee-keeper." I have procured one, and am perfectly satisfied with it. I have not the least doubt but that I shall get better returns from it than from the hive I have in use. I wish to express my thanks to "A L. B. K." for obtaining it for me. I hope to let you know the results another season.—R. A. CLARK, *Kent*.

TRADE CATALOGUES RECEIVED.

James Carter & Co., 227 and 238, High Holborn, London.—*Choice Bulbs.*
 Dobbie & Co., Rotbesay.—*Flowers and Vegetables.*
 William E. Martin, 20, Market Place, Hull.—*Dutch Bulbs.*
 William Paul & Son, Waltham Cross.—*Catalogue of Bulbs and Winter Flowers.*
 Cooper, Taber, & Co., Limited, 90, Southwark Street, London, E.C.—*Bulb Catalogue.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Exhibiting Stocks (*J. S. L.*).—For the purpose of exhibiting a stem with side branches is eligible, as also are stems without side branches, the judges then determining which represents the best culture.

Worms in Lawn (*Largis*).—As you are particular about having a reply in the "first issue," we can only say soak the lawn well with perfectly clear lime water. We are just going to press. Letters to which full replies are expected should reach us on Thursday, Friday, or Saturday.

Rose Buds (*Amateur*).—It is impracticable to state with any degree of certainty the time that elapses from the first appearance of a flower bud to its being fit for exhibition: it may be a month or more, according to the kind, and the conditions, favourable or otherwise, to its development.

Rose Leaves Discoloured (*Idem*).—The discoloration on the upper surface of the leaves is evidently due to the smoke, we having experienced similar deposits on the foliage of Roses when growing them in the vicinity of a large manufacturing town before the Smoke Nuisance Act came into operation; but in your case it is more pronounced, due probably to the sulphurous vapour and gases from the burning coal pit refuse, which, as we know from experience, is very prejudicial to vegetation, particularly when the fumes are brought to it by a strong wind whilst the atmosphere is moist.

Grapes (*H. B.*).—The Grapes sent in a paper box were smashed, and the juice almost turned the letter accompanying them into pulp. Only a portion of it can be read. The Grape in question is apt to be spotted, and extreme care is requisite in ventilation. So far as we can see you do not describe your practice in regard to temperature or ventilation.

Crossing Primulas (*J. E.*).—In fertilising short-styled Primulas with pollen from those having short stamens it will be necessary to divide the corollas in both cases, carefully removing the anthers from the flowers that are intended to produce the seed. A small camel's-hair brush is convenient for removing the pollen from one flower to another. If the plants are placed out as suggested seed will be readily obtained, but you cannot ensure any particular cross being effected. It is immaterial whether the plants have previously flowered or not.

Preserving White-hearted Cabbages (*A. A.*).—The best plan we have seen tried was to take up the plants, or cut them down level with the ground when the heads were quite dry, and cover them, stems, heads, and all, in dry bog earth. We have also tried the same in burned charred rubbish, but not with such good effect. They will keep a good while in a cool, dry shed, with their stems stuck in soil; of course, the place in all cases must be dry.

Insect Eggs on Rose Leaves (*T. H. G.*).—The eggs appear to be those of the Lackey Moth, *Bombyx* or *Clisiocampa neustria*, though it is not usual to see them at this season, but the caterpillars are probably late in hatching this year. They are small, nearly black, and very hairy, and do not appear to be particular as to food, as they eat the foliage of forest, fruit, and Rose trees, though not usually doing great damage to the latter. Search for the rings of eggs and crush them with your knife.

Disputed Prize Money (*H. D.*).—If you are paid the money in

one class, we should think you would have no difficulty in recovering it in the others; and according to your statement we fail to see a valid reason for withholding a penny. The "other side" might possibly, however, put a different complexion on the case. In the absence of that, and if your employer and the head gardener support you, you appear to be on firm ground. You can have the card returned if you send us a stamped envelope directed to yourself.

Muscat Grapes Shrivelling (*William*).—A temperature of 80° to 85° in the day by fire heat alone is excessive, and calculated to induce premature shrivelling. We should lower the night temperature to 65°, the top ventilators not being quite closed, and not force it much above 70° in the day with fire heat solely, but it may rise steadily to 85° with sun heat. You do not describe your method of ventilation, nor indicate the weight of the crop; it may possibly be too heavy for the Vines.

Cottagers Exhibiting (*J. R. W.*).—At exhibitions of garden produce in which classes are provided for cottagers they ought to be framed on an equitable basis; and beyond all question under gardeners in gentlemen's establishments have an undue advantage over labouring men and cottagers who are not employed in gardens. No objection can, however, be sustained this year if the rules are complied with; but action can be taken to amend the rules, or make classes fair for all before the next exhibition.

Pruning Roses (*K. O.*).—The very weak and the very strong wood of all Roses should be pruned in July, not in October or November. After the first flush of summer bloom is over every Rose ought to be "regulated," which means the same as the summer pruning of Currants and Gooseberries. The very weak wood of all Roses ought to be cut out at the end of October, and all the unkindly and weak Roses you see here and there on standards ought to have their annual winter thinning before October has passed. All moderate Roses to be pruned in March, and all very strong ones not till April.

Successional Peaches (*J. M.*).—As you have Early Beatrix, Royal George, and Noblesse on the front trellis, and three very excellent varieties they are, we may state that Bellegarde ripens about the same time as Royal George and Noblesse, or only a few days later. It is a very excellent Peach. Perhaps Barrington would best meet your requirements, or Belle Bance, a variety of Grasse Mignonne, but larger and later by a fortnight. To succeed the Barrington, Walburton Admirable is a large good Peach, and Sea Eagle is also large and excellent. Stirling Castle is only a form of Royal George, and very fine, being hardier, and good in every respect.

Oil Stoves in Peach House (*J. W.*).—The fumes from petroleum-heated stoves will not injure the Peach blossom and embryo fruit, care being taken to insure thorough combustion, and to use the best or crystal oil, though two or even three stoves might not answer your purpose in such a long house. It is very desirable to remove the roof lights where they are moveable, and expose the trees fully from the leaves falling until the bloom buds are swelling and showing colour in spring, when the lights should be replaced. Failing being in a position to remove the roof lights, ventilation should be given to the fullest possible extent through the winter. The Chrysanthemums will not do the Peach trees any harm provided they do not shade them before the leaves have fallen, and the house is not kept close and warm for them.

Melons not Swelling (*Puzzled*).—Melons not swelling to a good size is often a consequence of the soil being too loose so that the roots ramify through it quickly and produce rampant growth. Melons, however, have not swelled to their usual size this season, due, we think, to the dull cold weather, which has not been favourable for the elaboration and assimilation of the food supplies, therefore they are expended on growth instead of concentrated on the fruit. We can only suggest that the soil be made firm, so as to cause resistance to the roots and check exuberant growth, and the foliage be kept rather thin so as to effect the thorough solidification of the growth, causing it to transmit supplies of elaborated and assimilated matter to the fruits, upon which not only depends their size but their weight and quality.

Mushroom Spawn (*Miltrack*).—We remember answering a question on this subject some time ago, but we do not think it was sent by you. The mycelium in old Mushroom beds varies exceedingly. Some we have seen used successfully by persons able to select the best portions; but failures are far more numerous than successes, otherwise the practice would have become general long ago, whereas exactly the reverse is the case. The thickest and most prominent threads—the strongest-looking of the spawn—are the most likely to be chosen by the inexperienced, and the most likely to fail. If you use it, proceed experimentally. It is not nearly so reliable as the best brick spawn, and if what you have had has proved satisfactory, you cannot do better than procure more from the same source. When the mycelium is used from beds, larger pieces are inserted than of brick spawn.

South-east Wall for Vinery (*W. C., Gloucestershire*).—The wall covered with a house similar to the other part used as a Peach house would no doubt enable you to grow good Grapes. The foliage would not be particularly liable to scorch, provided due attention were given to ventilation in the early part of the day, and reducing correspondingly early in the afternoon, so as to utilise the sun heat. For the early house four rows of 4-inch pipes—i.e., two flows and two returns, and to grow and keep late Grapes well they require to be started in good time and assisted with fire heat in the early stages and at ripening; indeed, in a cold season like the present it is necessary to employ it right through;

therefore, we advise an equal quantity of piping for the late as for the early house, it being more advantageous to have a gentle warmth in the pipes than, by having little piping, be under the necessity of heating the surfaces highly to secure the requisite temperature.

Grapes Scalded (A. B. C.).—The Grapes sent are what are popularly described as being scalded, due, it is said, to the sun shining on them before the moisture deposited on the berries in the night is dissipated. But that theory is not sustained in the examples before us, for there are shrunken berries all round the bunch, and in parts where the sun could not reach. The injury, instead of being the result of excessive heat, we believe is caused by a moment of extreme cold, which always accompanies evaporation, and the more active this is the greater the degree of cold, and the more likely the tender cuticle of the fruit to be injured. The atmosphere of the house has been too damp, coupled with, we suspect, a too low night temperature; though you do not say a word on the temperature that has been maintained, nor the system of ventilation practised—indeed, you leave us to guess everything, except your having Ferns in the house. Grapes can be grown with a few plants in the house very well if care is exercised in watering and ventilation, at the same time maintaining proper temperatures. The colder a damp house is at night the greater the deposition of moisture on the fruit, and the longer the ventilators remain closed in the morning the wider they are usually opened, and the greater the outrush of air and moisture, including evaporation from the fruit; then follows the collapse in the form of shrinkage. Raise the night temperature 5°, whatever it may be now, not entirely closing the top sashes, admitting more air by degrees early in the morning, keeping the increasing heat under your control, and further injury may be averted. Are you not overcropping the Vines? The lateral bearing the fruit is very weak indeed, and the stalk of the bunch too. The majority of the leaves in the box we suspect were not taken from the Vines bearing the chilled fruit, and if our surmise is right it is a little curious you should have put them in and said nothing about it, as they might have misled, the character of the leaves affording a better index of the condition of Vines than does a half-grown bunch of Grapes.

Broccoli Dying (W. N.).—Your plants are attacked with the ambury, a disease known as club root and finger and toes. As you have been a gardener so long you may consider yourself fortunate in not having been troubled with a case before. It is a very bad case, judging from the examples sent, and the evil may not be easily eradicated. Cabbage and Broccoli plants are frequently infected with ambury in the seed bed, which infection appears in the form of a gall or wart on the stem near the roots. This wart contains a small white maggot, the larva of a weevil. If on the gall and its tenant being removed the plant is again placed in the earth where it is to remain, unless it is again attacked, the wound usually heals, and the growth is little retarded. On the other hand, if the gall is left undisturbed the maggot continues to feed upon the alburnum, or young woody part of the stem, until the period arrives for its passing into the other insect form, previously to which it gnaws its way out through the exterior bark. The disease is now almost beyond the power of remedies. The gall increases in size, encircles the whole stem, and prevents the sap ascending, consequently sufficient moisture is not supplied from the roots, the leaves wither, and the plant dies. The ambury usually attacks these crops when grown for successive years on the same soil. This is precisely what might be expected, for where the parent insect always deposits her eggs, some of these embryo ravages are to be expected. The ambury may usually be avoided by frequent transplantings, for this enables the workman to remove the excrescences upon their first appearance, and renders the plants more woody, the plant in its tender sappy stage of growth being most open to the insect's attacks. Late plants often escape when early ones succumb. Plant any you may have, after cutting off any small excrescences, dipping the roots as advised on page 111 last week. Give the ground when vacant a good dressing of gas lime as there advised, but it must not be cropped for three months afterwards. If you cannot wait so long, or procure gas lime, give a still heavier dressing of ordinary lime, and you may crop the land a week or two afterwards. The whole garden should be limed.

Phylloxera on Vines (King's Weston).—We had no difficulty in finding both insects and eggs on the roots of the Vines you sent us. They are seriously attacked with phylloxera, and can never be expected to do any good until that pest has been eradicated. The Vines should be cleared out at once, for to retain Vines in the condition in which yours are is only a waste of time, and no treatment, however good and skillfully applied, will insure a satisfactory crop of Grapes. The only proper course open to you is to burn the Vines, roots as well as tops. The whole of the soil must be cleared out and burnt, so that the destruction of eggs and insects that may be attached to small roots amongst it will be certain of destruction. The soil should then be carted away some distance. The whole of the drainage should be removed, but before doing so give it a thorough soaking with boiling water and salt, a strong solution; failing this thoroughly saturate the drainage with a strong solution of petroleum, say half a pint to each gallon of water that may be necessary. This done, wash every particle of soil out of the walls and pillars upon which the pipes are resting; in fact, every part of the house in which it is thought possible insects or eggs may be secreted, not omitting the wires, pipes, and woodwork of the house. This done, the base of the border must be thoroughly saturated with the same solution. Then go over the brickwork again, syringing thoroughly into every crevice a solution of muriatic acid and water, a 3-inch potful of the acid in each gallon of water will make a sufficiently strong solu-

tion. Be careful to keep this acid off your clothes or boots, for it will burn them. After this we advise all the brickwork to be pointed with cement. To save labour every hole and crevice can be filled up if the cement is mixed in small quantities, very thin, and applied with a white-wash brush. When this has set wash the pillars and all the brickwork with boiling hot lime. The house should be well painted. If you have other Vines near it may be necessary to destroy them also, but that is a matter that must be decided on the spot. At any rate the house should be kept from Vines, at least for a season. Use it for other purposes. If you have convenience raise Vines in another part of your garden and grow them in pots for a year before planting. But in spring place a young Vine in the house you have been cleaning, and examine with the aid of a glass its roots at intervals of a month to see if they are perfectly free from phylloxera. The extermination of this pest depends entirely upon doing the work thoroughly, for half measures will only end in failure and disappointment. Do not use the old drainage again, but cart it away and put down fresh drains. No fault whatever in this matter can attach to you, for Vines under the charge of many good gardeners have fallen a victim to this pest. Some of the grubs on your Cauliflowers were the same as those referred to, and others resembled the larvæ of a weevil. We should say your land requires a heavy liming. The name of the flower sent is *Lythrum salicaria*.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*G. C.*)—The specimen was a poor one, and had suffered greatly in transit; but it resembles *Dietamnus Fraxinella*. (*W. R.*)—*Odontoglossum crispum*, a good variety; 2, *Masdevallia Harryana*. (*H. S.*)—*Erigeron asper*. (*R. O. M.*)—*Campanula Trachelium*.

COVENT GARDEN MARKET.—AUGUST 8TH.

HARD TIMES.

SWEET are the lessons of adversity when turned to good account, and many a farmer will have reason to bless rather than curse the hard times through which we are passing, when the struggle is ended, and he is once more launched upon the smooth waters of prosperity a wiser and better man. For we hold that it is not a mere question of capital as to whether a man is passing successfully or not through this great crisis in agriculture, but rather the possession of ability in farm management, the gift of adaptation in his practice so as to "meet the times," holding his hand in that which he proves to be unprofitable, and striving where there is a margin of profit to add to it by every possible improvement in culture and general practice.

More than once at public meetings for discussion of the agricultural depression have we pointed out as a healthy and inevitable outcome of it, that superior farmers were not only holding their own but were gradually rising to higher things, not altogether as the poet sings, "On stepping stones of their dead selves," but rather by an intelligent grasp of the situation and its remedy. This is the better class of men into whose able hands the land must eventually fall, and however worthy others of the old easy-going school may be, it is inevitable that they must fail. It is not to the legislature or anything outside that we look for relief, but rather to downright earnest effort on our own part to obtain more and better produce out of the land, and more of the middleman's profits in the disposal of it. So far as is possible producer and consumer must be brought together and the middlemen avoided, but this cannot be done without intelligent co-operation among farmers. Is it not a disgrace and shame that so many middlemen find it worth while to attend every market of importance to come between producer and consumer? Very few farmers have to avail themselves of special market trains in comparison with middlemen, and yet we not only see crowded carriages on such trains, but prosperous wealthy middlemen travelling in first-class carriages upon the profits which fall so readily into their hands. We make no unjust reflection upon them, for they are perfectly justified in doing all the business they can, but we do wonder that an effort is not made to prevent hard won money from falling so easily into their possession. We may surely take a lesson from them in perseverance, tact, energy, and all that goes to build up the character of a keen man of business.

To come to particulars of improvements in farming we may turn first of all to Wheat. "Surely the depreciation in value of one commodity only—namely, Wheat—should not be sufficient to ruin British agriculture!" said an able writer in the pages of a contemporary recently. Nor has it, we reply, for not only has agriculture taken a turn for the better, but in Wheat growing generally there is a marked improvement. Writing from the very centre of the great corn growing district of East Anglia, we are able to say that throughout Suffolk the Wheat crop is excellent, not only in its promise of a yield of remarkable abundance, but in the evidence of the exercise of care in the selection of pure seed. Some of the very best crops of Wheat we know of are on farms where sheep folding is largely practised. Sheep and corn farming have long been united, and the union will become even stronger in the immediate future, for under skilful management it has proved more profitable than corn growing by the aid of any other manure ever can do; while the sheep are "growing into money" the land is being stored with fertility. Very different is this practice to that of a long fallow with frequent ploughings and a heavy dress-

ing of farmyard manure. A long fallow should really be regarded as a necessary evil when, and only when, land is foul with weeds, and not as an indispensable necessity to rest land. Of many a field of Wheat, if the corn is well harvested, we may venture to say the yield will be five quarters and upwards; and we know that under good management such results are fairly profitable. We pay very little heed to published returns of corn averages, for we know they are false and misleading. There are really no means in existence of obtaining a reliable return of the quantity of corn grown per acre. The Board of Trade returns may give the number of acres under Wheat, but unless each farmer were to give the exact quantity of Wheat threshed by him, how can it be known what quantity is grown? So-called market returns are published, but they are altogether unreliable. We may mention one market in particular of which a report is published of the total quantity of corn bought and sold, where certain merchants assert they have made no return for years, and we are strongly of opinion that without an Act of Parliament we shall never have precise information about this matter.

WORK ON THE HOME FARM.

Of the progress of work there is really very little to say, for farm work of all kinds has been hindered so seriously by wet weather that it has been practically in a state of stagnation. Haymaking has been prolonged beyond all precedent, and much hay has been spoilt, especially upon marsh lands, which have been flooded, and in several instances the hay carried away by the water. Early winter Peas kept for seed have sustained much harm too, and much Trifolium and Clover saved for seed has been spoilt. The seed became full grown and almost ripe, the mowing had to be done, rain followed persistently day after day, and much of the seed started into growth.

Corn generally has suffered, much of it having been beaten down by heavy rain. We have seen winter Oats down as level as though a roller had passed over them; much Barley is also lodged, but Wheat so far has not suffered in this way. We have in drives seen several fields of Wheat with the ears of a very dark hue. Mildew is spoken of by farmers as inevitable if the weather continues so cold and wet. Well, we are not wont to play the part of an alarmist, and if only bright hot weather sets in now we may hope for an abundant yield of excellent corn. But if we do not have the much-desired change from abnormal cold and wet to bright skies and real summer weather, the summer is likely to prove most disastrous. Wheat has already risen to the profitable rate of 40s. a quarter, and sheep have gone up in price at a rate which has induced much rash speculation. If only Wheat could be kept at such a price with a good harvest before us there would be an end to hard times for farmers. An advance in price, however, generally leads to an increase in corn importation, and we may expect a glut of foreign-grown Wheat in our ports very soon.

Dairy farmers may be congratulated upon an abundance of food upon pastures such as they have not had for many years. They ought to have a well sustained yield of milk, and there can be no excuse for them if they fail to produce first-class butter and cheese this summer. Late broods of turkeys have suffered where the young birds have been allowed to run much into the long wet grass.

REMARKS.

29th.—Morning fair and cool, fair afternoon, rain from 6.30 to 9 P.M.

30th.—Foggy early, then fair. Thunderstorm with rain at 3.35 P.M., and rain at intervals till nearly midnight.

31st.—Fair throughout, but only faint gleams of sun.

1st.—Rain began at midnight and was heavy from 7 to 9 A.M. again about noon, and 4 and 8 P.M., with thunderstorm and 0.99 inch of rain between 10 P.M. and 1 A.M. on 2nd.

2nd.—Slight rain very early, fine after 6 A.M., and throughout the day.

3rd.—Very misty morning, then fine throughout, with a well marked solar halo in afternoon.

4th.—Dull morning, fair day but not bright.

A rather wet week, with temperature below the average.—T. S. TOMES.

NOTES AT KEW.

A WET season suits the light shallow soil of the Royal Gardens, Kew, much better than a dry one, and when it is followed by a period of bright summer weather such as we have experienced within the past week, trees and outdoor plants of all kinds look as fresh in August as they do in May or early June. It would seem that the public have fully learned to appreciate these beautiful gardens, for on last Bank Holiday it is said that nearly 60,000 persons visited Kew, far outnumbering several of the metropolitan popular places of amusement, and this, be it remembered, without even a band to furnish an attraction. The visitors who crowd these gardens at holiday time are certainly not all botanists or even horticulturists, but the numbers afford a satisfactory indication of how widely spread is the taste which finds gratification in the contemplation of well-kept gardens and their numerous occupants. The public sense of the benefit they derive is best indicated by their behaviour, and it seems almost impossible that such an army could invade a garden and leave so few traces of their presence; indeed a couple of days afterwards no idea could be formed that Bank Holiday crowds had occupied the grounds, all was as neat and gardenesque as the most exacting could require.

No unprejudiced person can visit Kew occasionally without being struck by the fact that repeated efforts are being made to not only increase the usefulness of these gardens, but also to add to their popular attractions, and the steady continuance of this policy will always entitle the directorate to a liberal allowance from the public purse. But I commenced this letter with the object of giving a few notes upon what especially attracted my attention in a hurried run through the gardens recently from the Richmond entrance to the Kew Green gate. The houses, with one exception were carefully avoided, because the heat outside was quite sufficient, and there was plenty to see without subjecting oneself to a vapour bath. In the arboretum alone an afternoon might be profitably spent, but I could only give a brief glance at a few shrubs or trees on the way. Near the recently opened refreshment house and the winter garden are several beds occupied with Leguminous shrubs, and amongst them *Colutea arborescens* var. *haleppica*, is now the most noticeable. The flowers are small, but numerous, of a peculiar bright orange-red colour, quite a fashionable tint at the present time. The old form of *C. arborescens*, the European Bladder Senna, which has been cultivated in this country for over 300 years, has yellow flowers, and the variety *haleppica* from Aleppo has been grown here for about 130 years, but has been ranked by many as a distinct species. They have both been in flower for some weeks, and last extremely well, the flowers being followed by bladder-like pods.

We have not too many large-leaved trees in gardens, and it is strange that the American Hickory, *Carya alba*, is not more frequently planted. Judging by its success at Kew this *Carya* is not very particular either as to soil or situation, and it would undoubtedly thrive as well in scores of suburban gardens as it does there. Even in towns it might be worth a trial, and too few experiments are made with a view to increasing the number of trees available for town gardens. The leaves are somewhat suggestive of the Walnut on a large scale, pinnate, with broad oval substantial pinnæ, and though not very closely branched the tree would be good in a small state for shade. In dry hot seasons we often see the golden leaved varieties of trees and shrubs in their

best condition, but this season they have been mostly rather deficient in colour. *Catalpa aurea* seems to be one of the exceptions, as, despite the long continued rain, it has coloured well, the broadly developed leaves having assumed a fine golden tint, and specimens 3 or 4 feet high look remarkably well. The Guelder Rose, *Viburnum Opulus*, is loaded with berries rapidly becoming of a bright red colour, and there will be plentiful stores this autumn in most gardens for those who use these berries in various decorations of flowers, fruit, or foliage. *Olearia Haasti* is a New Zealand shrub, the merits of which are perhaps scarcely known, although it has been before the public for about sixteen years. It would, no doubt, be found unreliable as regards hardiness in some districts of England, but against a wall or in nearly all the southern counties it would be safe except in severe winters. At Kew it is grown in both ways, several fine bushes in a border near the roscery, and another against a wall, very little difference being noticeable in the health or floriferousness of the plants. Compact bushes 3 feet high have a good appearance in the borders. The leaves are small, shining bright green; the flowers white, in corymbose heads produced in great numbers, and very fragrant. As a white-flowered Honey-suckle, *Lonicera japonica* is worthy of notice, the flowers large with broad lobes, pure white when first opened, turning yellow with age. The fragrance is especially powerful and pleasing, the growth strong and the leaves oval.

The general bedding in front of the Palm house and down the Long Walk has not had time to recover from the rains, but several simple designs are displayed that will be better developed in a week's time. In the herbaceous ground and on the rockery the continued wet weather has suited the stronger growing plants admirably, and a varied effect is produced in colours and habit. The rockery is particularly attractive, and certainly improves every season, as it becomes better furnished, the sites adapted for certain plants are ascertained, and as much naturalness as possible is introduced. One little nook where a miniature waterfall descends from a rocky ledge and escapes through a bed of marsh or moisture-loving plants is charming, because there is no irksome artificiality. In the background are large clumps of *Spiræa palmata* with feathery trusses of rosy flowers; in front of these, and similarly luxuriant, are masses of *Spiræa lobata* after the style of the preceding, but having graceful plumes of white flowers. Then comes a grand clump of the old garden favourite, the Bergamot, *Monarda didyma*, which has an abundance of its bright crimson flowers in close whorls tier above tier. The foreground is occupied by a vigorous plant of *Rodgersia podophylla*, the spacious leaves of which serve the useful purpose of concealing the outlet of the water from the "fall." This plant affords a fine artistic study in bold foliage characters, and though only 2 or 3 feet high it is by no means framed on a puny scale. The leaves are 2½ feet in diameter, five somewhat triangular divisions radiating equally from the apex of the petiole, 9 inches across in the broadest part, deep green, becoming reddish as they mature. It is very telling in the waterfall nook, and evidently likes a moist situation. Upon one of the higher "rocky ridges" bordering this recess is a stately *Yucca* with a flower stem 10 feet high, towering above the surrounding plants and completing a pretty little picture that is so free and natural that one is tempted to think it is not a designed arrangement.

An excellent system is adopted on this rockery, and has been frequently commended, the same idea being carried out in the arrangement of the plants in the greenhouse and other structures. This consists in grouping a number of plants of one kind together, thus showing their character very much better, and producing more beautiful floral displays than when small plants are dotted about singly. Of course there are some plants which are seen to more advantage singly than in groups, but this refers chiefly to those of strong growth or some peculiarity of habit which does not admit of associating a number together. Some plants are also of a gregarious habit, naturally growing in clumps, clusters,

patches, or even extensive tracts. Occasionally a single specimen will develop to unaccustomed proportions, but general effect has often to be considered, and this is best accomplished by the grouping method. One example of the style is afforded by a plant that is not well known in gardens, though it might usefully take the place of several other plants of the great Compositæ family. This is *Ursinia anthemoides*, a Cape plant, which has also been ranked under the genus *Sphenogyne*. The flower heads are 1½ to 2 inches in diameter, with narrow, spreading, even, bright yellow ray florets, and a narrow shining black zone at their base surrounding the central tubular florets. The leaves are finely cut in a bipinnate manner, slightly glaucous, and the plant is 12 to 14 inches high. It is both showy and graceful, and no doubt would be found useful for cutting. An allied plant, *Ursinia pulchra* (*Sphenogyne speciosa*) is similar, but the flower heads are somewhat larger, the leaves being green, this apparently being the same species as that labelled *Ursinia speciosa* in the herbaceous grounds.

The strange-looking plant with an equally strange name—*Statice Suworowi*—covers a little plot of ground in one of the recesses, its long close cylindrical spikes of rosy flowers twisting and curling about like so many floral snakes. It cannot be said to be beautiful, but it is peculiar, and is worth growing for the distinctness of its characters. *Calceolaria mexicana* has a good-sized recess-bed devoted to it with capital results, the slender graceful habit and foliage, with the abundant delicate pale yellow flowers, giving it an admirable appearance. It has also been tried in the flower garden, not in the formal beds in the broad walk, but near some by-walks, and with satisfactory results. The leaves are pinnate and serrate, the stems reddish, the flowers with proportionately large lower lips and very pale clear yellow.

In the "Herbaceous grounds," that is, the department where the hardy plants are arranged in their natural order, flowers are very numerous, and nearly every bed would furnish ample material for an article. I can, however, only give passing attention to a few. The great Compositæ family is as usual in the summer months strongly represented by flowering plants, but one specially arrested attention as little known in gardens yet likely to be of considerable service. It is *Calendula pluvialis*, which the label also informs us is the same as *Dimorphotheca pluvialis*, popularly known in some gardens as the Cape Marigold, and in the matter of euphony there is no doubt that the adopted generic name will be preferred to the discarded one. Botanists we know have grave responsibilities in assigning plants to their correct position, or in giving them new names, but it is unfortunate that they seldom pay much regard to the elegance of the names bestowed, and so we get such terrible titles as *Ostrowskya* applied to a beautiful plant that will certainly become a favourite in gardens, yet we can only expect the name to be distorted and misspelled. In M. Godefroy-Lebeuf's paper "Le Jardin" for the present month the illustration of *Ostrowskya magnifica* recently published in the *Journal of Horticulture* is reproduced (without acknowledgment, by the way) and in some remarks accompanying the figure it is said "In France they will never say *Ostrowskya*, they will commence by saying *Otrokya*, then they will suppress the O, and will finish by selling the plant under the name *Trokia*," and most will admit that the abbreviation would be an acceptable one. But I was starting to say something about the Cape Marigold, which is an annual that deserves to be as widely known as the common Marigold, for it grows readily in any ordinary soil, seeds sown in early spring producing plants that flower freely at the present time. The flower heads are 2 inches in diameter, the ray florets substantial, white on the upper surface and purplish beneath, the central florets yellow, with a slight purplish zone at the base of the ray florets. The plants are 12 to 15 inches high, rather compact in habit, and the number of flower heads produced should render them useful for cutting.

Still wandering amongst the beds of Compositæ, some so-called Everlasting Flowers are noted, such as *Antennaria margaritacea* with numerous small white flower heads and whitish leaves; the

elegant *Helipterum roseum*, with narrow glaucous leaves and pale to deep rose flower heads; *Ammobium alatum grandiflorum*, with strangely winged stems and white heads of flowers, and the indispensable graceful *Rhodanthe Manglesi*. All these are excellent for cutting and drying, together with *Helichrysum bracteatum* in many varieties. The double *Achillea Ptarmica* is a useful garden plant, the flower heads small, neat, and pure white, capital for cutting. *Crepis rubra*, with pale rosy blush flower heads, in the style of the Cornflower, is also worth a place.

Turning to another family, the Phloxworts—*Polemoniaceæ*—very attractive are the graceful little annual *Gilias*, mostly Californian plants that are not too frequent in gardens. Several species are flowering, but four of noteworthy merit are the following: *G. micrantha*, 6 inches high, small bright yellow flowers and short linear leaves; *G. tricolor*, 18 inches high, flowers white edged rose, a central zone of deep purple, and a yellow base, the leaves pinnate; *G. androsacea*, flowers white or faintly purple tinted, petals spreading, leaves long, linear, and hairy; and *G. capitata*, flowers small, blue, sessile, in dense umbel-like heads, leaves pinnately divided. This plant is much taller than the others, running up to 2 or 3 feet.

But these notes will occupy sufficient space for one week, and will keep a little in reserve for another letter.—MERTON.

CABBAGES FOR SPRING.

THE production of Cabbages in quantity, and as early as possible in the spring, being important with us, though sometimes difficult of accomplishment, has tended to increase the interest with which I have read "A Kitchen Gardener's" excellent remarks thereon, also the succeeding judicious observations of Mr. G. Hilton, and in support of the latter's contention that seed must be sown earlier than August to suit some districts and seasons, I beg to offer one or two instances of my own experience.

I may state that our seasons are comparatively backward, the position being an elevated one (600 feet above sea level) fully exposed, with a shallow soil resting on a cold clayey subsoil. Our usual practice had been to sow about the 25th of July, and then to plant out as soon as the seedlings could be obtained large enough for the purpose. Circumstances, however, have twice occurred causing a deviation from this rule, the first being in 1885-6, when in July of 1885 we planted late spring-sown Cabbages on a rather poor quarter for autumn cutting. These came on badly, only making extra large plants by winter, when it was decided that they should be cut for use on any occasion that other greens ran short. In the result they were allowed to stand through the winter, which had been severe, and had dealt hardly with the ordinary plantings, and I then observed to my surprise that they looked like forming hearts, so they were left, and we had 3000 splendid Cabbages a month earlier than our neighbours. About 1 per cent. only bolted.

The second instance occurred last year. The drought and the flea had conspired against the usual July sowing to such a degree that I could only count upon five thousand instead of twelve thousand plants. In this dilemma I turned my attention to April-sown plants, which owing to the same reason had remained small, standing thickly together. With my previous experience I did not hesitate to avail myself of this welcome supply, and the result this spring has been a magnificent bed of luxuriant Cabbages, not one in 500 of which bolted, but formed grand shaped hearts, such as compelled the admiration of those who saw them.

This year I reasoned that with such a continuous excessive rainfall it would probably require a longer season than usual to prepare the plants for their autumn quarters. I therefore sowed early in June. The seeds germinated very slowly, and the process of development into the rough leaf took a long time, so that the plants are still somewhat small, and are giving promise of being ready for planting by the end of this or the beginning of next month. I choose Battersea always to stand over the winter.—R. CATT, *Metropolitan Asylum, Caterham*.

WET WEATHER FLOWERS.

VIOLAS.

RAIN falling almost daily for weeks, and often heavily, rendering the month of July one of the wettest ever known, has afforded an opportunity for testing the wet-resisting power of outdoor flowers, and it would be interesting and useful if correspondents in various parts of the country would make known those that have been the

most satisfactory during the present season. So far as we have seen *Violas* have been in the ascendant, and it is a little surprising that these hardy dwarf-growing flowers are not more extensively grown. They are represented in the purest as well as the richest of colours. A row of the white *Mrs. Gray*, margined with a dwarf very dark *Lobelia*, at Swanmore, produced an admirable effect. *Ardwell Gem* has been a sheet of soft yellow throughout the rainy period, *Dean's True Blue* has not failed to assert its power over the elements, and the lustrous richness of *Archie Grant* has impelled almost everyone to ask for cuttings who has seen it. These are not mentioned as superior to all others, for it is possible there are varieties still better, and it is certain there are many not less beautiful but differing in colour.

Violas are grown more extensively in the north than the south, the northern climate no doubt suiting them; but is there not something in culture and management? Very satisfactory displays have been produced in the southern and midland counties, not this year alone, but every year, though it is equally true there have been many failures. These could be traced to two causes—natural unsuitability of soil, such as that of a thin, poor, gravelly nature, or errors in propagation and planting. The method of preparing and planting tender bedding plants seems to have become so firmly impressed on the mind as to suggest that in the estimation of not a few cultivators all plants intended for flowering in lines or masses during the summer must be prepared much in the same way, and planted at the same time. Raising *Violas* from cuttings in spring and planting them in May, as has been the case with thousands, is not the way to succeed, but to fail.

It should not be forgotten that *Violas* are hardy plants, and that they should be treated as such; although, like some others, *Carnations* for example, young plants are often the better for a little protection from inclement weather, but cold frames suffice, and thousands pass the winter without their sheltering aid. We have seen an acre of cuttings inserted in the autumn at Swanley, or, to be more exact, cuttings inserted a few inches apart in depressed rows 9 or 10 inches asunder over an acre of ground, and the following year the plants covered with flowers throughout the summer. The soil is of a heavy nature, which is what *Violas* like; but if the same plants had been planted with tender bedding plants after the middle of May they would have practically ceased flowering before half the summer were over, if the weather were by any means hot and the ground dry.

But *Violas* also grow with great freedom and flower continuously in comparatively light soil, provided it is deeply worked and enriched with cool manure, that from cow stables preferably, and stout young plants are inserted in March or as soon as the ground is in good condition for planting and the weather favourable for steady growth. Old plants are unreliable. They flower early, but not over a long period; and young plants that have been "nursed and coddled" in boxes, then divided and planted as if they were so many *Lobelias* at midsummer, will similarly fail, except in seasons like the present, which we cannot always expect, neither do we want. Plants raised from cuttings in September, and in March hardy and sturdy, bristling with suckers, will flower all the summer if a fair chance is afforded them. The great point is to have the roots actively working in deep fertile soil before the hot weather of early summer sets in, and then in dry districts to mulch the ground between and around the plants with cocoa-nut fibre refuse, leaf mould, or short decayed manure, giving them a heavy soaking of water occasionally; then they will be like *Calceolarias*, flower the more freely the hotter the weather becomes. No amount of sun will hurt either provided the roots are cool and moist, and this can usually be secured by working the ground deeply, manuring it well, planting early, and mulching early too, also freely.

There was never a better season than the present for commencing the culture of *Violas*. The plants are in full free growth and the ground moist. A dozen or two planted now in a suitable position, moist and cool, and well tended, would afford cuttings by the autumn, and a good stock could soon be raised. The best growths for striking and making the most satisfactory plants are those that spring from the base of the plants, or just within the surface of the ground, the stems solid and the growths flowerless, resembling *Watercresses*. Larger growths with hollow stems are not nearly so good, yet we have observed those chosen by men who have been told to "help themselves" to a few cuttings. They may strike them or they may not. They will fail if not inserted deeply, and then will not make compact, healthy, free and long flowering plants. As a rule the inexperienced do not insert *Viola* cuttings deep enough; an inch above ground is ample, and 2- or 3 inches, or even more, within not too much, as young growths that are wanted start from the parts in the soil. These are the mere outlines of culture of a beautiful and too much neglected class of plants, and perhaps some successful grower will fill in such details

that he thinks may be serviceable. There is no doubt of the attractive force of *Violas*. It was difficult to get near some well arranged stands from Mr. Dobbie at the Crystal Palace Rose Show, so keen were the visitors to inspect the flowers.—*EXPERIENTIA DOCET*.

For some years I have grown *Violas*, and have also endeavoured from time to time to call attention to their value in gardens generally, no matter on how great or how small a scale. I am pleased to see my friend, Mr. Dean, still as enthusiastic as ever among these favourite flowers, for there are few men who have striven in so many ways to bring the *Viola* to its present popularity as he has done. It is with much interest that I read the remarks concerning these flowers at page 113, and it is with even greater pleasure that I fully endorse what is there said of them. While we have our *Begonias* in a miserable plight, and *Carnations* and *Picotees* decaying ere they have had an opportunity of expanding their welcome blooms, and *Roses* in many cases as bad, the bedding *Violas* have never been finer. Particularly effective has been a favourite of mine, *Ardwell Gem*; it is the best of the light yellows, and fully illustrates the value of *Violas* when they reach the age of twelve months. The plants in question occupy what I regard as my front garden, devoted principally to *White Tobacco*, *Gaillardias*, *Geums*, *Iceland Poppies*, *Tuberous Begonias*, dwarf *Roses*, *Alstroemerias*, and *Lilium candidum*, growing much in their own way, and affording very pleasing results. *Ardwell Gem* was planted in this mixed assembly in June, 1887, and the patches of it are now 2 feet across, and have carried many hundreds of blossoms from the time they began flowering this year, which was in the latter part of February last, apart from what they did last season. As though they realised that they were doing better than the *Roses* they have clambered among the thorny branches, and thus produced a most natural and charming picture. Not only, then, as bedding plants by themselves may these *Violas* be grown and seen to advantage, but as carpets for other plants, and *Roses* in particular. Unhesitatingly do I reiterate the sentence contained in the last issue of the *Journal*, "Why do we so seldom see them in our public parks and gardens?" Are the managers of these gardens ever going to rest content with those of the cornuta section, while we have so many grand bedders possessed of equally grand constitutions, and, so to speak, almost incessant bloomers? Take for example a bed of standard *Roses*, what could be a more appropriate carpet for them than *Violas*? Can any other plant be mentioned as likely to prove more floriferous or more generally attractive and lasting, and withal so hardy and enduring, as these *Violas*? If additional effect in early spring was considered necessary, this could easily be supplied to *Hyacinths* or *Tulips* dotted over the bed. Take a bed of dwarf *Roses* planted thinly, and with such *Violas* as *Ardwell Gem* or *Countess of Kintore* amongst them, we have a permanent bed quite unique. *Violas* planted in this way as carpets need not be planted annually, since plants of twelve or eighteen months form a perfect sheet of blossom early in the year. All that is needed is to cut the old plants over closely in autumn, point the ground between them, and mulch with decayed leaves and manure. *Violas* generally look best after a good shower of rain; such being the case they have this year been exceptionally fine, and it is impossible to over-rate their good qualities.

For long ribbon borders many varieties are especially well suited, and of these *Mrs. Gray*, *Ardwell Gem*, *Queen of Lilacs*, and *Cliveden Purple compacta* are among the best. Some of the more compact growers are *True Blue*, quite a gem in its way, admirably suited as an edging to silver-leaved *Pelargoniums*, so dwarf is it, a fine blue withal, and possessing a good constitution, renders it among the most useful in the shades of blue. One of the prettiest effects I have seen this year was brought about by planting *Violas* between rows of *Pyrethrums* in beds; the rich and varied colours of both groups formed collectively one of the most beautiful pictures I have seen. Both were in grand condition in June, and the *Violas* still continue to do service. For a bold, rich, deep violet blue we have none to compare with *Archie Grant*; it is a handsome flower, well formed, wonderfully robust and free, and produces its flowers on stems 6 inches long. Such an one as this may be brought into excellent use in mixed arrangements of plants, and is also highly effective in the foreground of well-kept shrubbery borders.

To the list of whites given on page 113 I would add *Jefferyanum* and *Champion*. The first is a medium-sized flower, very free and continuous, while the latter is the largest white known to the writer. It is excellent for early work, and partakes of the style of *Pilgrig Park*; but has not so much blotch as that variety. There is another white which has been certified this year, and is named *Snowflake*. I do not see any improvement in it. It possesses the habit somewhat of *Pilgrig Park*, though dwarfer, whilst its flowers

are more closely allied to Mrs. Smith, though quite distinct. When all our whites have been tried, we have none to compare with Countess of Hopetoun, which is excellent in all respects, and likely to stand the test of time. Of golden yellows Bullion and Golden Prince Improved are remarkable for their profuse free blooming qualities. The Queen of Spring types I have not yet grown so well here in Middlesex as I have done in the midland and northern counties, and I intend testing what older plants will do for me in this respect. The young plants do fairly, but they lack the size and freedom to which they are prone in and around Birmingham for instance, so I intend leaving this year's plants or a portion of them to flower next season, and see if any improvement is made. Mrs. Baxter and Countess of Kintore are both excellent. Sir Joseph Terry is a deep velvet black, while Duchess of Albany, Dawn of Day, Skylark, and Spotted Gem are great favourites. One variety in particular needs more than a passing word of praise—it is Bronze Queen, than which we have few *Violas* destined to become more popular by reason of its most distinct and useful colour—a rich bronzy, shining chestnut. Those who possess this variety should make the most of it, for some of them will be in greater demand. Two other varieties which I had lost sight of I have procured again this season; they are Crimson Gem and Forerunner. Both varieties are first-rate bedders, of good form, and compact. The predominant colour of the first is defined in its name, while Forerunner is a rich violet or indigo blue shade, quite distinct. Any or all of these are calculated to produce a display in either large or small gardens of which no other plant can boast; nor does any hardy plant provide such a continuous wealth of bloom at so trifling a cost or with so little attention as these *Violas*, facts alone which cannot but bring them into their right position in the floricultural world. I can only advise the would-be cultivator to closely follow Mr. Dean's advice as to their culture and propagation if they court success. With regard to the brown aphid, which is rightly regarded as "a terrible enemy," I find a solution of quassia and softsoap very effectual in their destruction; but in this, as in most things, prevention is better than cure. And here, again, the reader will do well to follow Mr. Dean's advice, and keep his plants freely watered—an item which growers generally have not regarded as desirable at present this summer.—J. H. E.

TOMATO FAILURE AND DISEASE.

LAST season was unusually favourable to the growth of Tomatoes in the open air, the crops in many instances fully equalling what are annually grown in America, at least so I was informed by those competent to express an opinion in the matter. As a consequence more plants were prepared and put out this year than at any previous time, and as a great failure is the inevitable result, let the weather in August be what it may, the disappointment will be all the greater. Recently I saw several large breadths of ground, both sheltered and exposed, covered with Tomato plants, or enough to produce many tons of fruit, and these at present are not furnished with any crop. Strong plants were placed out, these being either staked or trained up wires, and kept disbudded, or rather cleared of all side shoots, but the flowers fell as fast as they formed, and if any set it will be in August instead of June. Those against walls throughout the country are not in a much better plight. Any that are furnished with fruit had these set before they were planted, and even against extra warm walls or the fronts of forcing houses the crops are very light. As yet I have seen none affected by the Potato fungus, but a good per-centage of plants have sickly foliage, or such as delicately constituted Potatoes have that are rooting in a cold and wet soil.

Under glass the crops are far from being satisfactory, the greatest difficulty being experienced in effecting a good set. The flowers were weak and pollen scarce, and the majority turned yellow and fell. To add to the tale of woe a comparatively new and very destructive disease has shown itself in places where many large houses are solely devoted to Tomato culture. This is known as *Cladisporium fulvum*, and as yet no remedy has been found other than removing the leaves as fast as they are affected. Perhaps I ought not to call this a remedy, as it is very certain when all the principal leaves are removed from a plant the fruit cannot attain either to a good size or good quality. At the fruit-growing establishment above alluded to, which is situated in Gloucestershire, and many miles away from any other Tomato houses, I inspected several span-roofed houses not less than 100 feet long wholly devoted to Tomato culture, and to all appearance not one plant out of the many hundreds grown were free from this destructive disease or fungus. It was sad to see such a number of long naked stems, and sadder still to think there is no known remedy. In Guernsey and Jersey the *Cladisporium* was very destructive last season, but in spite of various precautions it is still

worse this year, fruit as well as foliage being badly diseased. Evidently it is spreading through the country, and I am afraid the Tomato industry will receive a shock from which it will not quickly recover. This is much to be regretted, not only on account of the loss to the growers, to many of whom one or two failures may mean ruin, but also because of the check to the fast increasing love of and demand for Tomatoes.

At a recent meeting of the Scientific Committee of the Royal Horticultural Society, Dr. Masters suggested dusting the affected leaves with a mixture of sulphate of copper in fine powder and precipitated or newly slaked lime, this having been found efficacious as a remedy for mildew in the French vineyards. It has already been tried by a gentleman who owns several vineyards in the south of France, and is also much interested in wholesale Tomato culture in this country. Sulphate of copper and lime do check the spread of mildew, but it appears to be powerless against the more rapidly destructive *Cladisporium*, unless sufficient of it is used to destroy the leaves as well as the fungus on them. Diseases of fungoid growth are very hard to check, and especially so in the case of foliage that is not hard and smooth. This season is undoubtedly very favourable to the spread of mildew-like diseases not only among Tomatoes, but also Grapes, Melons, Cucumbers, and other fruit trees or plants. There is no remedy for the Potato disease, and I am afraid never will be; but in some seasons we escape infection, and the *Cladisporium* may be only a temporary visitation.

Some diseases are constitutional, and may be perpetuated by seed saved from affected plants. Each time I have raised Melon plants from seed supplied by a friend a disease has manifested itself in the foliage. At first large yellow spots appeared, these soon spreading, apparently eating away the hairs and upper surface of the leaves, and the plants had to be destroyed. No other Melons before nor since were similarly affected, and I am firmly convinced the disease was in the blood or constitution of the plants. It was not one, but several varieties apparently possessing strong constitutions that were affected. I shall be told the *Cladisporium* is spread by means of floating spores, but all the same I cannot help thinking it may be spread by the medium of tainted seed, or else how did it reach such an out-of-the-way and healthy open district as the western counties? As a large Guernsey grower stated in a letter to me, there is a fortune awaiting anyone who can devise a remedy for the *Cladisporium*, but although I have had sent me specimens of infected foliage in various stages, as well as diseased fruits, I liked the look of it so little that I would not keep it long on the place, or try to communicate the disease to our plants, with the idea of conducting a series of experiments. If it comes naturally I may then make the attempt, but it is doubtful if the honour and profit of the discovery will fall to my lot, or indeed to that of anyone else, or it would have been forthcoming ere now.

At the present time (August 2nd) there is prospect of more settled weather, and plenty of hot sunshine may yet do much to improve matters, more especially in the case of healthy plants that have set few or no fruit. Those grown in the open cannot, under any circumstances, be expected to produce and ripen many fruits, but those against sunny walls and under glass are more likely to do better. Many have erred in neglecting their plants. When it was seen no fruit was setting no further trouble was taken with them, and as a consequence the main branches are breaking down and a thicket of side shoots sprung up. No greater mistake could have been made, and it ought to be rectified, as much as possible, at once. All superfluous growth ought to be cut clean away, leaving only the main branches or leading shoots and a few strong side shoots where they can be laid in without crowding. This will encourage the formation and setting of a few strong clusters of fruit, and if the shoots are stopped beyond the second of these all will swell rapidly. The earliest may ripen on the plants, many more may be cut and ripened under glass, and the small green fruits can also be utilised for making into pickles.—W. IGGULDEN.

COLOGNE EXHIBITION.

AN International Horticultural Exhibition was opened at Cologne on the 4th inst. under the patronage of the Empress Augusta of Germany, Her Imperial Majesty being represented on the occasion by the Minister of Agriculture, accompanied by a brilliant suite of high military rank. The place where the Exhibition is being held, for it is to remain open till the end of September, is the Flora Gardens, a public resort of the inhabitants of Cologne, where horticulture is fostered under the care of the distinguished Director, Mr. J. Niepraschk, a name well known among the horticulturists of Europe. These Flora Gardens are on an extensive scale, beautifully laid out and planted with great taste and skill, surpassing even the Royal Botanic in the Regent's Park, which is the admiration of so many. The design was executed twenty-five years ago by Dr. Lenne of Berlin, and carried out by the Director,

M. Niepraschk, and it was to celebrate this twenty-fifth anniversary of its foundation that this Exhibition was held. A grand banquet was given in the conservatory, which was well attended.

Like most of the exhibitions on the Continent which are intended to extend over a lengthened period, this was no exception to the rule of being unprepared on the day of the opening. Besides the exhibition of flowers, which was held in the glass houses of the establishment, there were long ranges of sheds surrounding an open field of about three acres in extent, which formed an annex to the garden, and was devoted to collections of implements of horticulture and agriculture, machinery, heating apparatus, and, indeed, the usual class of articles which are met with in similar exhibitions in this country. The field was well laid out with winding walks, and its surface occupied with clumps of specimen Conifers, standard and dwarf Roses, ornamental trees, and flowering shrubs. Mr. Charles Van Geert of Antwerp had a very choice collection of specimen Conifers. On the opposite side of this from the machinery was a department representing vegetable products, such as grain, dried fruits, beverages, including the famous Lager beers of Germany and the noted wines of the Rhine, cider, perry and mead, and there was also a large exhibition of honey and bee-keeping apparatus.

The exhibitions in the houses were not of a very high order. Two good but not large collections of Orchids, and some ornamental foliaged plants from Ghent, along with a large quantity of marketable-sized plants, constituted the leading feature, but there was no attempt at an exhibition of specimen plants such as we are familiar with. One of the most gratifying incidents connected with the opening was the presentation of an artistic silver vase to M. Niepraschk by his students, with whom were associated Dr. Wittmack of Berlin as representing German horticulture, and Dr. Hogg of London, as the representative of the Royal Horticultural Society, both of whom felicitated M. Niepraschk on the happy event, as being not only the celebration of the twenty-fifth anniversary of his directorship, but also of his marriage.

In the evening of the opening day there was a display of fireworks in the gardens, and fortunately the weather was fine, but for several days the rain came down in unpleasant earnestness, which interfered much with the preliminary progress of the Exhibition, and reminding us of our own experience at Birmingham, when the tents could only be reached by walking on planks. The Exhibition will, as we have already said, be open till the end of September, during which the objects exhibited will be both numerous and varied.

A WEEK'S WANDERINGS. IN THE ISLE OF WIGHT.

"WHERE'S Orchard now, and what is he doing?" is an inquiry that has been heard by several readers of these notes during the past six months. Mr. C. Orchard having been engaged as a gardener most creditably and successfully in the neighbourhood of Croydon and Kingston-on-Thames for many years, became well and widely known, and by his willingness, or rather alacrity, to lend a helping hand to his fellow workers or to further any good cause in which they were interested, became highly respected. He was, moreover, and still is, one of the notabilities in the Chrysanthemum world, and there can be few men, if any, who have a more intimate acquaintance with the several varieties and their peculiarities than he has. He was also a pioneer in the cutting-down system near London for grouping, and no more effective arrangements of the plants have been seen than as produced by him at the Kingston National and other shows. Therefore it is that Mr. Orchard became so well known and so popular that interest was manifested in his whereabouts and present occupation. It was known he was somewhere in the Isle of Wight, but by no means known what he was doing. So I thought I would go and see.

It was said last week he was discovered in a delightfully situated house overlooking the bay of Sandown, but that was not quite exact. The "Dark Pasha," for he is no Elaine, was first found prospecting on the pier at Ryde. He seemed to be expecting the steamer from Stokes Bay—Mr. Molyneux arranging that I suspect, for he advised that route from Swanmore, not telling me that I should be met. "Had you come to Portsmouth," observed Mr. Orchard, "I would have met you there, and we could have crossed by one of our steamers to Bembridge, and gone on by our railway to Brading. It would have cost nothing, as I have got a pass for you till the end of the month, and it can be renewed." The words "our" steamers and "our" railway sounded a little strange out of the mouth of a gardener. Some gardeners have a "trap" at disposal I know, if only a vegetable cart with a hamper to sit on, though at least one of my friends in the craft has a carriage and groom; but a gardener with a huge steamer, also a railway at command, was quite a novel idea. I thought of an episode in the movements of a duke and a doctor, and how much better off I was than they were. I think I may tell the story, for it is true. A certain doctor not unknown in the horticultural world, and a noble duke whose name is honourably and deeply engraven in the records of history, went to see a garden, and when they arrived at the station found nothing but a cart with a board across. Without any waiting for the carriage they requi-

sitioned the cart and jogged across the country, enjoying the trip immensely. There is nothing like a novelty for making people contented while it lasts.

But to hark back. The steamer and railway sequel only dawned on me by degrees. When my friend tried to explain things I thought he was joking. To my inquiry as to what he was doing, I was told I should "see in the morning." His answer to the request for the size of his garden was "about 800 acres;" that to what they grew in it, "Oh, 400 or 500 acres of grass, 200 or 300 acres of nothing, 4 or 5 acres of vegetables and flowers, besides, ducks, chickens, rabbits, and 4,000,000 oysters." But I should "see in the morning." Well, I did see stretching out before me a narrow level tract of land about two miles long, the railway skirting one side of it, connecting the station near us with the distant steamers. In this great flat tract were bare patches of blowing sand, a far greater extent of waving meadows, with stacks rising slowly between the showers, the garden towards the end, the oyster tanks shimmering in the sun, and next the sea, on a spur of land, the "Royal Spithead Hotel." Then I began to comprehend. The sea is eating away the land in many places in the Isle of Wight, but here it has been driven back and held back, and what was a dank and noisome morass will soon be rich firm grazing land, and this with the harbour formed by throwing a huge embankment, which forms a broad road, across the valley, developing trade and traffic, will be the reward of the promoters of the great enterprise. The land thus reclaimed is under Mr. Orchard's management. It is his duty to secure the crops and make the still barren patches productive, to supply the hotels with vegetables and flowers, and generally to look after everything that is

FIG. 16.—MR. ALDERMAN COLDWELLS, J.P.

not of an engineering nature for his chief and head of the whole huge concern—the harbour, the hotels, the railway, and steamers—Mr. J. C. Coldwells, once a gardener, and with a gardener's instincts still, and now and for a long time an alderman and a magistrate.

Mr. Orchard appears to have nothing to do but ride to and fro in his train and look after his men; but having a high sense of duty he is not the man to let anything go wrong or be lost through inattentiveness. He contrived to get some hundreds of tons of hay in splendid condition—by far the largest bulk and of the best quality I saw in the island. He does not do what some haymakers do in showery weather—spread the grass all over the ground, and prevent it (the ground) drying, but works on the wind-row system—that is, clearing broad strips of ground to dry, then throwing the grass on them lightly, and the strips from which it is removed dry in turn. The quicker the ground is dried in this way and the hay turned back the quicker it is made; and it is a fact that he secured tons in excellent condition when much spread all over the land from which the moisture could only escape by rising up through the hay, and of course not drying, it was spoiled. This is no new plan, but a good old one regularly practised in some districts but not in others. Sheets and pulleys have also been a profitable investment in protecting the stacks in the process of building. So many persons, including gardeners, are interested in haymaking that these remarks may be permissible.

It is astonishing to see the freedom with which not only grass and Clover but garden crops grow in this sea bed of sand. When dry it blows in clouds, and for a time not even weeds will grow in it; but when the salt is drained out and the excess of sulphur dissipated, verdure follows. The upper part of the valley, or that most distant from the sea, has been reclaimed for generations, and no finer grazing land can be found. Animals thrive astonishingly on the herbage, probably because the sand is rich in phosphates. It is as poor to look upon as can

be imagined, yet in the fenced garden Peas are growing as luxuriantly in this bed of sand as if they were in turfy loam trenched 2 feet deep. And it is the same with Cauliflowers, Cabbages, and allied crops, while roots of all kinds—Carrots, Turnips, Beet, Potatoes, are of exhibition quality. Yet no manure of any kind is applied to the land or sand. Individual roots of Parsley exceed 2 feet in diameter, and a beautifully curled and crested leaf plucked off was 10 inches long, not measuring the bare stalk, and 9 inches across. All kinds of flowers that have been planted grow in the same remarkable manner. A respectable armful of Sweet William flowers could be cut from a root, a last year's seedling. It is long since I saw such a display of these good old border plants. The colours of many were extremely rich and the trusses enormous. Stocks and Asters luxuriate, and even Roses grow well in this sterile looking sand. Visitors to the hotel are loud in praising the beauty of the flowers and the quality of the vegetables, the latter they say excelling any had elsewhere. It is certain there must be something good in this sand, or so much that is excellent could not come out of it. I have seen no parallel to this culture except in a field of sand at Knowle Hill, Chertsey, in which Mr. Thomas Sharpe grew splendid crops of the finest of Strawberries year after year without any manure. He probably grows them still unless he has made his fortune and retired from business. Strawberries will yet be seen growing in the old sea bed at Brading, but Mr. Orchard says he must have the bare places covered first, or the sand blowing from them, as it does at times in clouds, would make the fruit gritty; yet it is in the same kind of sand that the crops above named luxuriate. Trees have been planted, forming copses, and have grown with equal satisfaction, but they do not root deeply. There appears something below too strong for them, and the roots, of Poplars especially, run along the surface, some of them scarcely buried, like tightly stretched waggon ropes; and there is one of the finest of fences running across the head of the harbour. It is of Furze or Gorse (*Ulex*) from seed sown by Mr. Coldwells three or four years ago, and the plants allowed to grow undisturbed; it is a perfect hedge for an exposed position.

The gardening experience of the manager in chief of this great undertaking has doubtless been of immense service, and his strong common sense and knowledge, acquired by practice in ground work, has enabled him to overcome engineering difficulties of no mean order, and to combat the waves successfully, and make a tranquil harbour in which craft of various sizes ride safely. Mr. Coldwells is his own engineer, and has a practical man to carry out his plans, just as Mr. Orchard carries out all other details on the estate relative to land improvement, and cultivation. It will be of interest to give a brief outline of the career of one of the most successful men of the day who has risen from the gardening ranks. Let it be said at once that Mr. Coldwells is not a good gardener spoiled. Prosperity, I sometimes think, has made men uncomfortable when in the presence of their once fellow labourers. They seem scarcely to know what to do with them. To ask them into the dining room would perhaps be making too "free," yet to send them to the kitchen would appear "cold." I have had some curious receptions in my time. It was evident my "hosts" scarcely knew what to do with me. I suppose I always was a little difficult to deal with; but servants' hall or dining room or some sort of a compromise between the two is all the same, though what I least like is the troublesome compromise. There was no nonsense of this kind at Brading. "Come along," says Mr. Coldwells, "we must cross the harbour to my house, and then I am going to run to Ryde in the yacht. Will you go?" "Go, yes; the sea is a little rough, but if it is safe for you it will be safe for me." A boat was hailed for a ferry over; but before we were half across the harbour the water rushed in, rising higher and higher. "The cork's out," shouted the man, but it could not be found. "Pull, or we're in for it," shouted the captain. A third gentleman in the boat turned white, and I felt so, but said nothing. "Pull, pull, your best," was the next shout, "or in we go; can you swim?" I began to think I had done writing, but a few more frantic strokes and we were safe. "The man must be a fool to put off in a boat like that," was the first and not unnatural remark; but we were soon calm again and commenced botanising.

Mr. Coldwells' marine residence is situated on what is called the St. Helens Duver, a large extent of sand hills and hollows clothed with grass, with clumps of Furze here and there, also many wild flowers, all having sprung up after the waves were driven back and further encroachments defied by the strong sea wall. The Duver forms the links, said to be the best in the kingdom, of the Royal Isle of Wight Golf Club. The large hotel is the great rendezvous of the Golfers, and they have a pavilion on the ground. Growing out of the bare sand the Sea Holly (*Eryngium maritimum*) was conspicuous by its blue spiny crowns, the Great Sea Bindweed (*Calystegia soldanella*) was attractive by its large barred flowers, the Evening Primrose (*Oenothera biennis*) has established itself, and banks and bracs are carpeted with the golden and white Stonecrop (*Sedum acre* and *S. album*). The Sea Pink (*Armeria maritima*) forms part of the turf, which in the autumn is studded with the Autumn Squill, *Scilla autumnalis*. It is curious that all these plants, and many others, should have sprung up in such numbers in the old sea bed, which is now as dry as a rabbit warren. Such are the surroundings of Mr. Caldwell's residence; his other home is at Croydon.

He served as head gardener in situations in Essex, Middlesex, and Surrey, and speaks interestingly of his early career. When a lad he joined the Stoke Newington Gardeners' Society, which held fortnightly meetings, at which essays were read and discussion on them encouraged. The late Mr. McElroy was a member, and Mr. Taylor, who wrote a

treatise on the Chrysanthemum. At one of the meetings a Mr. Lamb exhibited Chrysanthemum blooms in a Dahlia stand, cut from plants secured to a wall and protected from frost and wet by an overhanging board. They were the first blooms so staged and caused a sensation. The only named flower Mr. Coldwells remembers was Annie Salter, and this for a very good, if somewhat old-fashioned reason—he "knew a pretty girl of that name." From this stand of blooms sprung the Stoke Newington Chrysanthemum Society. Mr. Coldwells has been an exhibitor at and judge of flower shows, and he established a branch nursery for Messrs. Pridham & Sanders of Croydon, he subsequently became manager of the Croydon Irrigation farm, and eventually bought a partnership in a large outfitting business, which he greatly developed. Having an active mind he took part in public affairs, and for years has been an eloquent advocate in the cause of temperance. He has taken great interest and worked successfully in the preservation of footpaths, open spaces, and commons. He has sought by long endeavour to improve the habits and elevate the minds of the working classes. He was an active member of the Croydon Local Board of Health and largely instrumental in obtaining a charter for the town, of which he became one of its first aldermen and a magistrate. I once had the pleasure of hearing Mr. Coldwells speak at a dinner after one of the Kingston Chrysanthemum shows, and can understand his power in debate. I did not know who he was then, but there was no mistaking his being a gardener. Finding him in the Isle of Wight was a surprise. He is a magnate of land and sea there, the man for a great enterprise, and who succeeds in everything he undertakes. But perhaps his greatest trial is before him, in a Parliamentary contest. Though a political nondescript I hope I am loyal to my craft, and if I had the casting vote in two constituencies and could put genuine gardeners, a Whig and Tory, in, I would do so, then ask them to dance the Tullochgorum. Thinking some readers might like to see the portrait of a gardener who has made such an advance in life, I ask for the insertion of that of Mr. Alderman Coldwells.—A WANDERER.

RESULTS OF RAIN.

I do not know whether others have noticed it, but it is worth observing in respect of Rose plants the wonderful amount of wood they have been and are making. Notwithstanding, or rather in consequence of, the constant rainfall, I have had and am having, now in the middle of August, such blooms as I can never remember at this season. Many are coming truer than ever before, and for clearness of colour quite exceed the July Roses. I doubt not other people are recognising the same. If the wood can only ripen it can hardly be doubted but that there will be excellent material for next season. As a compensation to other and disastrous results, it would seem as if this summer soaking has a valuable effect upon the growth of trees and bushes. I observe a second blooming upon Reine Marie Henriette and others of very unusual excellence.—A. C.

ROSE HER MAJESTY.

I WILL excuse Mr. W. R. Raillem making any apology to me in behalf of Her Majesty. I think it must have been some other friend whom he bantered in his pleasant way on the occasion of Mr. Bennett winning the gold medal with Her Majesty. That was the first time I saw the variety, and then and there took a dislike to the Rose individually and collectively, much to the surprise of my friend Mr. Curtis of Chatteris, who went into ecstasies over it. But to show how I respect the opinions of others whom I deem wiser than myself, when the Rose came into commerce at last I bought six extra sized plants in pots of Mr. G. Paul, and turned them out into the open ground in May. They did not bloom that season, 1886. I budded from them, and have now about a dozen plants, but have not had more than three or four blooms this year. I have plenty of mildew on them. The habit of the Rose, though vigorous, is ugly, and no Rose in cultivation as an exhibition Rose has so many or such thick thorns. Would the most gushing young man (I am elderly) venture to present a bloom of Her Majesty to his tender rosy-fingered Aurora? He would be a barbarian. No, I do not like Her Majesty, but just tolerate her for the chance now and then of getting a bloom such as Mr. E. B. Lindsell showed at Darlington. Alas! I was not there.—F. H. G.

P.S.—I think the Rose I so praised was Queen of Queens, but that Rose too has quite disappointed me.

ROSES IN WINTER.

THE production of Rose blooms from the time they fail outside up to Christmas had only passing notice on page 429, last vol. The declining months of the year may safely be regarded as the most difficult in which to maintain a supply of blooms. But this may be accomplished if free-flowering, good growing varieties, such as Safrano and Isabella Sprunt, are chiefly relied upon, and plants prepared for yielding blooms at that period. I cannot say that blooms could be profitably grown from a market point of view, because it is next to an impossibility to produce

those that would possess the requisite colour and size to be saleable during those months. For home use, however, delicate buds in quantity may be had if a house is devoted to their culture. Few flowering plants will yield a return that will be more highly esteemed.

Two courses are open for the attainment of this object. The one is to grow the plants exclusively in pots, and the other in pots up to a certain stage, eventually to be planted out. For years we followed the former, but prefer the latter, not solely on principles of economy, but because the plants that will be recommended for the purpose have youth and vigour on their side. Young plants worked in spring or rooted from cuttings are suitable for this purpose. Plants on their own roots are decidedly the best, because they push up more freely from the base, although the former may be resorted to if wood for cuttings is not available. If the plants are to be grown in pots they should have the treatment described for young plants up to the middle of September, when they may be allowed to make growth and form buds. For planting out, cuttings must be rooted in February, and potted twice, first into 3-inch and finally into 5-inch pots. If the plants are grown in heat until the middle of June they should be gradually hardened, and placed afterwards in cold frames with a fair amount of ventilation until the end of July or early in August, when they should be planted out. From that time small Melon houses or similar structures can be set at liberty, and are admirably suited for the purpose. Some of the soil in which Melons have been grown can be removed, and leaf soil moderately rough may be added to nearly one-half, with about one-seventh of horse droppings or decayed manure. A few wood ashes may be added; they will do no harm, but the reverse. Old Melon soil is only given as an illustration. If good loam can be used it is preferable, but it is not necessary—in fact, the short time they are intended to occupy this position soil that has produced another crop will answer the purpose very well indeed. The soil need not exceed 6 or 7 inches in depth.

A large number of Roses can be planted out in even a small structure, as the beds may be filled to start with, and the more turned out the greater the quantity of flowers that will be produced. Planting moderately thick without unduly crowding is advised. The plants should be turned out without breaking their roots, and in ten days or a fortnight they will be rooting freely in the light soil surrounding them. Keep them close for a time after planting, and then carefully but liberally ventilate until the middle of September. As the temperature decreases both by day and night admit no air to the plants. The plants will grow freely, and push up strongly from the base by the end of October. If the temperature at night is kept about 55°, they will continue growing, and flower profusely up to Christmas; in fact, we have had them continue until the end of January, when it has been a pity to remove them, for the blooms have then increased in size and colour.

What is to be done with the plants afterwards depends upon circumstances. If the house is wanted and blooms from other sources are ready to meet demands, they should be kept cool to harden them, when they may be lifted and stored in frames to be planted outside in February. If it is decided to pot them, they can be lifted with fairly good balls of roots, placed at once into 7-inch pots, and stood in a cool house or cold frame. Under any circumstances frost should be kept from them for a time. They should rest until the middle of March, and then be pruned closely back, nearly level with the surface of the soil, and allowed to break into growth under cold frame treatment. These plants need not be followed further, for they can either be grown for culture in pots to flower again in the autumn, or, better still, for flowering in spring the following season. To save the labour of raising young plants, they can be retained in the 7-inch pots and planted out again for flowering up to Christmas, but should not be kept after the second year. Persons wanting blooms at that period, and not having prepared for the purpose, may purchase worked Roses now in 5-inch pots, and plant them out as detailed.

Rose blooms can be had from plants established in pots if they are started early in the season, so that a good growth is well matured by the middle of June, when they may be repotted if they need it, and the thin puny growths removed by the middle of August. The plants will then break into growth, and have formed quantities of flower buds by the time it is necessary to house them. By close genial treatment indoors the plants soon break into growth, even while producing the flowers that are set outside, and flower freely up to Christmas. But when plants are confined in pots for several years, and subject to flowering at that period, they soon become weak, and need a season's complete rest to recruit them. How to recruit exhausted plants will be more fully dealt with in another contribution.—WM. BARDNEY.

THE CHISWICK APPLE AND PEAR CONFERENCE.

A SCHEDULE and circular of the Conference to be held in the Royal Horticultural Society's Gardens at Chiswick, October 16th to 20th this year, have just been issued. The schedule enumerates thirteen classes for Apples, one each for fifty, twenty-four, and twelve varieties, with four others for twelve and six varieties of dessert and culinary varieties respectively, the others being for Apples from cordon, bush, or pyramid trees, standards in orchards, Pear trees on pyramid stocks as grown and sent to market, and for new varieties. To Pears ten classes are devoted, arranged in a similar manner, but the largest class is for thirty-six varieties. No mention is made of prizes or medals.

In the circular the following particulars are given:—

"In consequence of the great success of the Apple Congress in 1883,

and the Pear Conference in 1885, and in order to bring up the reports then published to the present date, the Council of the Royal Horticultural Society has decided to hold another Conference on Apples and Pears in the Gardens at Chiswick, from the 16th to the 20th of October next. In the previous conferences it was held desirable to secure the representation of every variety of these fruits in cultivation, whether valuable or otherwise, so as to arrive by comparison at an estimate of their worth. This having been done, and duly recorded in the published reports, it is not now considered necessary to go over the same ground again. In the present Conference it is proposed to invite the exhibition of such varieties only as find favour, or may be considered thoroughly worthy of cultivation.

"One object of this Conference is to illustrate by facts and examples the present state and future prospects of commercial fruit culture in this country. It is consequently desired that contributors should endeavour as far as possible to furnish samples of fruit that are in favour in the markets of their several localities. All fruit growers are invited to exhibit, and the more widely the collections are procured (within the limits of the schedule), the greater the interest the exhibition will create. It is very desirable that every collection should be accompanied with as much information as possible with regard to soil, exposure, and physical condition of the districts in which they have been grown; for which purpose the accompanying forms are enclosed. All fruits exhibited should be distinctly labelled with the name or names under which they may be known, and as the specimens sent are strictly for examination, they must necessarily be at the disposal of the Committee if required.

"Persons willing to contribute papers bearing upon the subjects in hand are requested to communicate with Mr. Barron at an early date, stating the particular subject they are prepared to treat of. Arrangements for reading or publishing papers will be made by the Committee. All packages should be addressed to Mr. A. F. Barron, Royal Horticultural Gardens, Chiswick, and must be delivered on or before Monday, the 15th of October. Exhibitors staging their own fruit may do so on the 15th or on the morning of the 16th, to be ready for the inspection of the Committee. Notice of intention to exhibit must be given not later than Wednesday, 10th of October, stating the class or classes in which it is intended to exhibit, or the amount of space that will be required. All exhibitors will be admitted to the gardens free, and will receive a certain number of tickets, according to the extent of their exhibits. It is recommended that heavy packages be sent by goods train."

MAKING IMPROVEMENTS.

ON reading the article in No. 2073 (June 21st) of the Journal on the "Duties and Difficulties of Gardeners," many thoughts flitted across my mind. I thought of old associations, and many incidents of early life came vividly before me. Thoughts of old friends, successful friends, and unsuccessful friends. Some appeared to flourish and thrive go where they would. On the other hand, some always seemed to find uncongenial surroundings; although they appeared to strive hard and keep on the road to prosperity, yet there always seemed to be a something to frustrate their endeavours. That the article by "An Old Servant" contained some trenchant and practical sentences must be readily admitted; but the genial ring which pervaded it, and the excellent advice given throughout, made it most instructive and readable. At the same time not a few gardeners were "hard hit," and I for one have not the least objection in stating that some of his thrusts went straight home. But to return to the heading of my paper. After nearly thirty years' experience in the busy world of horticulture I have had some ups and downs, and have seen many who were considered good men fail, and even fall, when a few moments' serious thought would have saved years of toil and trouble. Some have failed at one obstacle and some at others; some from being too precipitate, and some through want of energy; whilst not a few have blundered on the subject of this paper—"Making Improvements."

It is a fact tolerably well known that in many instances on a gardener taking charge of a new situation he is not slow to find, or at least attempt to find, fault with his predecessor, and his inauguration of his new office is marked by a continued agitation for alterations, or, as he is pleased to call them, improvements, when at the same time his employer is very reluctant that the existing state of things should be materially disturbed. With elderly persons, more so than with younger ones, a disposition is often evinced to retain all the old associations of their homes as long as possible, and I think in such a case a gardener should do all that he can towards keeping the place in a satisfactory state on the old lines to which his employer has become attached. I was in charge of an old garden some years ago, and not being satisfied with one part of it, I had the temerity to suggest an improvement, but was met with a mild rebuke that has lasted me to this day. It was an intimation that when the owner wanted improvements of the nature suggested, which involved cutting down trees and planting, he would take me into his confidence and say what he wanted, as he added, "I shall most likely have to pay." It may be readily inferred that if I

thought improvements necessary after that I was careful not to express such thoughts to my kind and considerate old master, with whom I stayed till the day of his death.

It is doubtless a mistake for a gardener to insist on so-and-so being done, especially when he finds his employer is opposed to it. Better to go on in a quiet way and make the best of existing arrangements than to be perpetually grumbling. Many vacancies have been caused by a few words spoken without sufficient thought on the resources at the command of a gardener being of such a primitive nature. On taking charge of a new situation it should be a gardener's business to find out, by casual conversation with his employer, or by direct questions, whether or not alterations are desired, and then act on the answer returned, and from which useful hints may often be derived. A continual grumbler is likely enough to become a trouble to an employer, and sooner or later the partnership will be dissolved, when by a little thought and tact on the gardener's part he might have had a comfortable home and creditable employment for many years. I have in the course of experience observed many changes made in gardens; many have been decided improvements, and are at the present time standing proofs of the gardener's ability. But there are cases of the opposite character. Fine trees, ornaments to any place, and splendid shrubs, specimens that many would give much to possess, have been destroyed, all for the sake of making a change and producing a new effect that did not approach in dignity the old.

Fine old trees and specimen shrubs are not the production of a day, and I know of few subjects in gardening that require and are deserving of more serious thought than the destruction or preservation of such. Alterations and improvements in any department are not matters to be trifled with, and all such should be carefully thought out in detail before operations commence. That there are many gardens where much improvement is needed I am well aware, and it may be that the owners of such are equally aware of the fact, and also probably aware where the expense of such improvements will fall. Moreover, the owner of an estate has lived a long life and become so accustomed to his home surroundings that the gardener would meet with a poor reception in case he advanced any improving ideas. But, after all, as has been said, gardeners and servants should try and do what is right and in accordance with the wishes of their employers. If improvements are desired in the gardener's charge he should set about them in the best way that he possibly can. If, on the contrary, he finds that such changes are not agreeable he should not be continually finding fault on that score, but try and make the best of existing circumstances, and he will then be more likely to gain confidence and feel himself secure in his home.—ANGLIAN.

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 461, last vol.)

BEFORE quitting the subject of Roman influence on English horticulture exerted during the centuries when our island was a province of the mighty empire that has never had a successor, a few more facts may be noted which have some bearing upon the history of horticulture in these islands. That there followed a period of depression after Rome gave up the sovereignty is certain, but if the men went many of the plants they brought here remained and propagated themselves far and wide, till after generations wondered how they had arrived and from whence they came. As the Grape is the principal berry of Italy, even to the present day, doubtless this was one of the first fruits introduced by the Romans, and they had many varieties, some vaguely described as thick-skinned and thin-skinned, long-berried and round-berried, and it is at least probable that some of the vineyards well known in the Middle Ages, and which have left their impress in the names of places, were composed of Vines descended from Italian stocks. And the Vine was cultivated with much attention, almost enthusiasm, as was the Olive. If the Romans experimented with the latter in England their success would be limited, though Miller asserts that trees placed against a warm wall at Kensington grew well and produced fruit in 1719. And there are Olives which have stood the open air many years in the mild climate of Devonshire.

It would seem that the principal fruits introduced during the Roman period were the Almond and Fig from Syria, the Citron from Media, the Peach from Persia, the Pomegranate from Africa, the Apricot from Epirus, the Cherry from Pontus, Apples, Pears, and Plums from Armenia. At least one kind of Apple, perhaps more, grew in Britain previously. Of these only a part would, if exposed, yield fruit, owing to the coldness of our winters, unless the climate was more equable formerly, as some argue, but the evidence is shadowy, except that the extent of forest and marsh was much greater than now; our climate was certainly more moist, perhaps hotter in summer. Of Apples it is reckoned that the Romans

knew about twenty-five kinds; of Pears more, thirty-five or upwards, distinguishing those suitable for eating and for cooking. Their Plums are classed as black, white, and mottled, there being several varieties of each, one evidently our Prune. At least eight kinds of Cherries, one too tender when ripe to bear carriage, another small and hard-fleshed. Only the black Mulberry was known to the Romans, and no varieties of the Peach or Apricot are mentioned. Of Chestnuts they had six sorts. The Walnut was valued for its fruit, called sometimes the "food of the gods," and they cultivated a kind of Filbert, the fruit of which they ate baked or roasted. Strawberries the Romans seem to have had, but the heat of Italy did not suit them; history fails to tell us whether they took under cultivation the British Hauthois. The Quince and the Medlar were grown, but not particularly esteemed; our other fruits were unknown. In their kitchen gardens the Romans had many plants familiar to us, afterwards forgotten in England through ten centuries nearly, except where a few of them happened to be cultivated by the monks. Our leguminous vegetables, our esculent roots mostly, the Brassicas, the savoury Alliaceous tribe, various salad and sweet herbs, were not only grown by them, but they received the personal attention of the Roman gentlemen, whose kitchen gardens were sometimes almost extensive enough to be called garden farms. Prominent favourites were the species of Gourd, which occupy a position between fruits and vegetables, such as the Cucumber and the Melon. It was one of the odd superstitions of both Greeks and Romans that these plants disliked the presence of the female sex, hence women and girls were cautioned to keep away from the beds where they were growing. But on the other hand, women might be of some use, for it is stated by Democritus that when a plot of land is infested with caterpillars if a woman go round it three times barefooted, and having her hair hanging loose, they will die. I wonder whether it has occurred to anyone to try this "insecticide" during this prolific caterpillar season. Evidently the Roman gardeners had great faith also in the doctrine of lucky and unlucky days, and even hours; thus they advised that Beans should be gathered just before dawn, and Vines always pruned at night if the crop had been a failure. Then there were notions current as to what operations should be performed in the increase of the moon, and what in its decrease. Perhaps these might not be altogether so foolish as may appear at first, for I have spoken to gardeners who think the moon has some influence upon vegetation; but it would require careful and repeated observations to ascertain about this. Fond as the Romans were of flowers, while their sway extended over Britain they had not many species so far as we can tell, but they were grown freely. Lilies, Hyacinths, and Roses were prominent, also some showy Composite plants of doubtful identification, perhaps our Aster and Marigold; with Rose bushes the walks were often bordered, and they were also grown in clumps. As there rose a demand for Roses out of season Pliny says the gardeners hastened their development in spring by the application of warm water to the roots. The passion for a profuse display of Roses is stated to have come from Egypt, where at entertainments people strewed their rooms with the entire flowers (or the petals) to the depth of more than a foot. No scientific arrangement of plants was attempted by the Romans in any of their gardens, but they were accustomed to place plants used for medicine or flavouring in beds by themselves, apart from other species.

Curiously enough the departure of the Romans from Britain did not finally extinguish the influence of Italy upon our horticulture, as after an interval this was renewed by the doings of the ecclesiastics, amongst whom there was always a good percentage of Italian foreigners. This occurred in two ways—firstly, by the diligent cultivation of a variety of plants in the monastery gardens, where the pursuit relieved the tedium of cloister life, and many species were kept up from century to century which were well-nigh unknown to the outer world; and secondly, through the visits paid to England by a peculiar class of religious men, the palmers, about whose history most of the dictionary-makers show themselves ignorant. We get the clue to it from the fact that some hairy caterpillars were called by our ancestors "palmer worms," because they seemed to be always wandering about. A pilgrim went a specified journey and returned; a palmer spent his life in going from place to place, and often carried a branch of Palm, but as old historians tell, he also not unfrequently brought to these western lands seeds or fruits obtained while he wandered in hotter climates, and described the plants he had observed there.

The three Saxon tribes dwelling on the shores of the North Sea who sent parties of emigrants to Britain in the fifth century were not likely to favour the advance of horticulture at first. In one particular, indeed, they followed in the footsteps of the Romans, for they were diligent growers of corn, and it was still largely produced in Britain, where, under Roman management, the island had raised so much grain that it was sent to countries on the

Continent. But of flowers and fruit the Saxons took no heed, if they cultivated some of the common vegetables, their leaders thinking that any of these peaceful arts would lessen their warlike enthusiasm, hence they had devised a law that those who tilled lands should exchange them with others at the end of each year, a plan which was decidedly unfavourable to outlay or improvements. It is probable the Saxons introduced from Germany one or two heads of Cabbage or Kale, these vegetables being favourites with them. The old Saxon name for February means "Sprout-Kale," referring to the fact that about this time the sprouts formed on the winter stems were fit to cut. The love of Brassicas amongst the Germans is still further exemplified by the circumstance that in Scotland, where many of them settled, the people have even to this day remained steadfast to vegetables, which has given the country its repute of being the "land of Kale."—J. R. S. C.

ANTIRRHINUMS AND PENTSTEMONS.

THE former are much later than usual, and scarcely so good as during a hotter season, but the Pentstemons are very fine, both as regards the spikes and the size and colour of the flowers, a showery summer evidently suiting them well. Both ought to be lightly supported by stakes, and if the old spikes are removed as soon as the flowers are shabby this favours a better supply of flowers from side shoots. The surest way of perpetuating any superior varieties is to propagate by cuttings, these striking readily, and may be easily wintered. Short flowerless shoots may be slipped off the old stems near the ground and at once dibbled into handlights set in a cool and somewhat shady position, or say at the foot of a north wall. They ought to be kept rather close, shaded and watered as required, and when rooted have the lights kept off them. If rooted early, or before September, the plants may be placed out and wintered in the open borders, or better still, in beds, but those struck much later ought to be treated more like *Calceolarias*, being wintered under glass, given plenty of air, and protected from severe frosts. These may be planted out early in the spring and will flower strongly during the summer. Many beautiful varieties of both *Antirrhinums* and *Pentstemons* may be obtained from a packet of seed of each, or seed may be saved and at once sown in preference to waiting till the spring, when so many other plants require the room and attention. It should be sown on the surface of a pan of previously moistened fine sandy soil, and be lightly covered with more of the same. Set either in a handlight or on the ground in a cool position, and covered with a square of glass, the seed soon germinates, and when large enough to handle the seedlings ought to be dibbled out thinly in boxes or pans of fine light soil. They soon become large enough to transfer to the borders, the better plan, however, being to keep at least half the plants under glass, or where they can be lightly protected and taken care of during the winter.—W. I.

THE COMMERCIAL REALISATION OF FRUIT.

(Continued from page 127.)

JAMS.

THE manufacture of jams furnishes a valuable outlet for a large quantity of fruits, but for the small farmer it forms the lowest remunerative outlet for fruit. It is a system that is attaining considerable proportions in a few districts, but they are so few that they are as a drop in the ocean of our fruit supply, and the total quantity of the crops absorbed in this direction is remarkably small and must remain so. To make jams profitably requires capital and experience, both to produce the article and to dispose of it. To produce the goods on a large scale an outlay is necessary for sugar, jars, labour, cases, &c. To make a sale for a quantity it is necessary to educate the public with a knowledge of the quality and character of the particular goods, and this involves an immense expenditure of money, time, and labour, a matter that no farmer can carry through upon its legitimate basis for an ordinary crop. Unless a farmer is prepared to do this work and incur the incidental expenditure, he must be prepared to send his goods into the ordinary outlets of commerce, and then they enter into competition with the so-called jams or fruit preserves that are made up and sold to the public at low prices, which the trade know, that although they bear the name of almost all fruits, are simply made of Apples, and very poor Apples too, the different flavour of the fruits being supplied by chemicals, the "seasoning as does it," very much on the principle of Sam Weiler's sausages. Coming into competition with that particular class of goods, the small farmer engaged in jam operation stands but a poor chance of making a profit. Should, however, a body of farmers club together to make jams, the very fact of their organisation would give their goods a standing and value in the market, although they might find that the same labour and expense incurred in preparing the same goods as high class dessert fruit and sweetmeats would result in much speedier and more profitable sales. Crystallised and glace fruits retail at from 1s. 3d. to 2s. the lb. They do not absorb so much sugar as jams. Evaporated Apples sell wholesale at 6d. per lb., equal to 3s. 6d. per bushel,

they are retailed at 10d. per lb., equal to 5s. 10d. per bushel. At 10d. per lb. the prices range with green Apples to the consumer at 1½d. per lb., so that it will be seen that there is an abundant margin of profit for those engaged in their manipulation.

WHAT TO DO TO MEND MATTERS.

The one essential step necessary to create an improvement in the present unsatisfactory condition of things is for fruit growers to combine in their own districts, and form a union for the provision of a regular supply of fruits that may be prepared and realised under the supervision of themselves, and by the direct control of their own representatives and managers. Such organisations should take the shape of the co-operative societies that the working men of the country have formed in every direction, which have proved simple in formation and effective in working. It may be safely said that the lines that the industrial classes have drawn for their co-operation to buy may be rendered equally available for the producers of the nation, who should co-operate to sell. It must be borne in mind that the co-operative stores in each district are perfectly self-contained, conducted, and localised, so that the management of each society is entirely in the hands of those of the members in the locality. Yet each of these stores is affiliated with a central organisation composed of the delegates from each society, that effectively purchases in bulk all the goods that the societies require in detail. To such an extent have these organisations grown that they now number 1450, and the aggregate purchases made by their members last year exceeded the enormous sum of £32,000,000. This immense concentration of buying power that the working classes have created for themselves is something for the producers of the country to look forward to, and they should make every effort to secure the share in that trade that is available in their direction. Desires have been generally expressed of the necessity of producers and consumers getting more within touch, and middlemen done away with as much as possible. The problem has been frequently tried, and failure has been the inevitable result. The solution of the problem will be found in this direction: Producers must co-operate to sell, and when they have their organisation formed on the same lines as consumers they will be able to approach each other officially, ascertain each other's requirements, and much trade will be the result.

To refer practically to the subject which we have met to consider, I may say that the fruit farmer must largely gain by the co-operation and assistance of commercial experience, as from the nature of his crop benefits are obtained in every direction by the organisation which is the outcome of it. The season for each particular kind of fruit is very short, and markets in every direction require incessant watching to note the changes that take place. Fruits vary in character, quality, and condition greatly, and particular kinds can be best dealt with in different directions. Again, a sudden change of weather will in one night so affect a large quantity of fruit that it must be immediately dealt with or its value is lost, while a few days' bright sunny weather may quickly ripen a crop and bring it so forward as to render it necessary to market it immediately, when by glutting the market its value is materially depreciated. These are contingencies that it is necessary to provide against, and only by commercial organisation and combination can this be done effectively and with profit; but no individual farmer can possibly provide against these contingencies by himself, for if he provided against the whole he would require an enormous organisation that his own crop could not profitably utilise continuously, and if he secured himself against a portion of the contingencies the chances are, that as the unexpected always happens, circumstances would arise against which he was not prepared. Then, again, the bulk and weight of fruit is enormously great compared to its value, and the cost of its transport is extremely heavy in comparison with the amount realised. Commercial experience and organisation would offer facilities for beneficial arrangements being made for the conveyance of fruit to its destination that isolated working could not command, and it would also enable a simpler and more direct system of distribution to be carried out. It may be noted that every saving effected in this direction, being an addition to the profits and tending to the advantage of the grower, the larger the combination the greater are these benefits likely to be.

(To be continued.)

ARTIFICIAL MANURES.

THE latest remarks of Mr. Coombe on the above familiar subject came as an agreeable surprise to me; the tone maintained was distinguished by moderation and reason, the writer having evidently satisfied himself that a judicious combination of science, practical experience, and close observation must form the keystone to future horticultural successes. My desire for a ray of light to disperse the darkness in which I have for some time been groping to find out the way in which your correspondent would put his theories into practice, has met with a generous response, and not only a ray but a perfect flood of light has been given which is highly satisfactory in many respects. My opponent in describing his mode of procedure in preparing suitable plant food shows us that his methods differ but little from those usually practised. Instead of a host of mysteriously wonderful and minutely proportioned compounds, we have simply placed before us the usual potting materials, such as loam, leaf soil, lime, sand, charcoal, and (mark the elastic term) artificial manures. We are also treated to the candid admission that in compounding these mixtures for plant food, if the mind is well stored with knowledge, it matters little whether gained by scientific research or experience and observation. Exactly, this is the point I have been

endeavouring to uphold throughout this discussion, by showing that although I fully believe in the great help science is towards the attainment of the object we have in view—viz., that of producing the best results by the simplest means, yet we must not set too high a value upon mere scientific knowledge, for the simple reason that unless scientific research is conducted with mathematical precision from beginning to end, its teachings are often misleading. Now, this cannot be done in ordinary practice, but must be left to special investigators to find out how far it is really essential to supply to plants the constituents of which they are built up; practical men will then not be slow to seize upon that knowledge and turn it to good account.

Mr. Coombe seems to have taken a decided objection to my use of the words minutely and nicely proportioned combinations, but at the same time admits that a properly proportioned combination would be a minutely proportioned one in a certain sense, but not in the way I have tried to maintain. Now, he has already given us an idea of the way in which he would find out what is a properly proportioned combination for particular plants—viz., by analysing the ashes and thereby calculating how much potash, lime, phosphoric acid, &c., is contained in a given quantity; these are some of the principal constituents, but in addition to them there are numerous other elements present in varying degrees in each particular plant. Now, the question is, How far is it necessary to supply these minor constituents with increased results? I believe it is quite possible to, from a scientific point of view, to manufacture a food containing all the elements, exactly proportioned as in plants and fruits, but as some would have to be given in a soluble and others in an organic form this proportion would not continue so for long, unless the soluble constituents were repeated at intervals, for reasons I have previously given, that certain elements are fastened up by the soil, and can be retained for future use, while others are not. Another important point that should be kept in view is, that before we can claim to be able to compound a really "properly proportioned combination," on the lines indicated by him, we must analyse the natural substances used, considering how extremely varied soils are in different localities. For this reason I cannot admit that in practising science by halves he is acting on lines so superior to what he chooses to call the haphazard system. And although I still believe that for practical purposes these minutely or so-called properly proportioned are not necessary, so long as the principal constituents are present, yet I should not for that reason think of consigning to the flames the works I have quoted from. On the contrary, I intend to add to their number, as I am a firm believer in steady and continual progress in my walk of life; and in regard to the usefulness of chemical knowledge to gardeners, I consider the true course to pursue is to find out the dominant forces that regulate plant life, and to use them in a simple and practical manner. Another proof that these compounds, as advocated by my opponent, are not necessary, is proved by the fact that some kinds of artificial manures are equally effective for plants that differ as widely as plants can do in their chemical constituents, as, for instance, Chrysanthemums and Azaleas. I fully believe with my opponent that in any occupation in life the key note to success is found in strict attention to details, but I would add, first find out that those details are really necessary, as trifling attentions, commonly known as facts, are better left alone.

With many of Mr. Coombe's remarks on the lime question I cordially agree. In regard to his disappointment at not receiving a note based on my practical experience, let me inform him that knowing the high value he sets upon scientific authority, I thought I would give him the scientific explanation first, and reserve the practical note for the next addition. We have not differed materially throughout this controversy as to the effect a dressing of lime would have upon a soil abounding in humus. The point he seems to be at variance with me is that carbonate of lime has the power of retaining moisture for the use of the future crop; and although I must admit that he has treated this subject in a thoroughly impartial manner, as he finds out that a scientific study of the action of lime would have some slight effect in causing more moisture to be retained, but considers too much stress should not be placed upon its usefulness in that direction, because in his opinion there are other and more powerful agents, such as humus, comprising organic remains, salt, nitrate of soda, &c. I am not prepared to say that those substances would not be equally effective on a sandy soil, and in the case of the former would be valuable for using in conjunction with the lime, and I am inclined to agree with my opponent, that it would not have as profitable an effect in causing a sandy soil to become more retentive as it does on heavy land in making it less retentive, for the simple reason that when used on heavy soils it neutralises the acids, which renders them unproductive, in addition to the mechanical action it would have when its chemical properties had been transferred to the surrounding soil. But notwithstanding these facts, lime is well known to be of considerable value in promoting the fertility of almost any kind of soil, if the right kind is used. When converted into chalk it contains a large percentage of phosphate of lime, which is a constituent of all plants. If Mr. Coombe will try the effect of an application of lime to a sandy soil, I think he will find he has under-estimated its value as a means of imparting to the soil the power of retaining moisture. I have on more than one occasion noticed this effect—although I must admit the soil was not particularly sandy, but still very light. A moderate dressing of chalk was given at the winter digging, and during the existing summer, when the soil was again dug, an examination of numerous small pieces of chalk showed them to be soft and moist when pressed between the fingers, and in many cases with small particles of roots clinging to them.

Your correspondent's explanation in reference to my statement that "while certain elements are absorbed by the soil and only given up again in small quantities others remain freely moveable, and a residue not quickly taken up would be wasted," has the advantage of originality if not of correctness, and it is about as definite as describing the geographical position of London by saying it was somewhere between Dover and Newcastle. By arranging extracts from my previous articles side by side he in reality supports the arguments he intended to contravene. "If the food administered does not contain the right proportions those elements in excess of volatile would be lost." Certainly; and herein lies the difficulty of manufacturing perfect and economical plant foods when some of the elements have to be given in a soluble form, because they are assimilated more quickly than the insoluble elements, and consequently the plants have to go short of these elements till a fresh supply is given, while they have still within their reach a plentiful supply of those substances that are not so evanescent. I maintain that this clearly shows that the best course to pursue is to give the solidifying agents in excess, because the residue would not be wasted, and supply the volatile ones at intervals as circumstances show they are required. I think it must be a slight oversight on the part of my generally shrewd opponent when he quotes from your correspondent, "B," in support of his own ideas; for although that writer says, "I think it is possible to produce a perfect plant food," he also goes on to say that, "Any scientifically composed food is sufficient for any plant requiring help in that way. It is quite possible, no doubt, that there may be in the composition something which is not required for every plant; but this is a matter of no importance so long as what the plant does require is present in fair proportions." This part of the quotation is altogether opposed to the views put forward by Mr. Coombe where there is the independent support he claims to have in support of his views; and whether my opponent's arguments or my own have carried the greatest amount of conviction with them I am willing to leave to the unbiased judgment of the numerous readers of this Journal.

Before concluding I will add that so long as those engaged in controversial subjects are guided by the admirable sentiments expressed in the concluding paragraph of my opponent's article they will, I venture to assert, perform a useful purpose without wounding the susceptibility of either, and also tend to promote in each a wish to become comrades instead of opponents. — H. DUNKIN.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE Hon. Secretary of this Society, Mr. Wm. Holmes, in issuing the members' tickets for the present year, calls attention to the extension of the programme, especially by the Provincial Show, to be held in the Corn Exchange, Sheffield, on November 16th and 17th. He also adds that "This additional item is arranged without any increased charge on the members. I hope, therefore, we may receive a large accession of new subscribers during the season, and so justify this fresh feature and re-imburse the Society the very considerable extra cost this Show and the new classes in our schedules will of necessity entail. The usual arrangement for 1s. admission tickets for non-members (available for any day throughout the year) is again adopted. I have a supply in hand, and it is as essential as ever that all friends intending to visit either of the Shows should avail themselves of them. By doing so our Society benefits, 50 per cent., but we do not share in any cash paid at the doors. These tickets may be had on sale or return, but any not sold must either be returned by November 24th, or paid for. The new catalogue is now in the printers' hands, and will be ready for sale early in September. I shall be pleased to forward copies in the order of application, 1s. 1d. post free."

SEASONABLE WORK.

CHRYSANTHEMUMS.—With the exception of the dwarf early varieties all Chrysanthemums ought to be kept staked and lightly tied up, otherwise the principal branches either break down or gradually bend to the ground. Once partly broken or allowed to become crooked they cannot well be again neatly staked upright, and it is very certain flowers produced near to or quite on the ground are of little value. All that is wanted is a fairly strong stake to each main branch, allowing the side shoots to grow out and flower in a natural manner. This will be found a far better plan than bundling a number of branches together only to spoil each other. Chrysanthemums are essentially moisture-loving plants, and if fine dry weather continues they will pay for a little attention in the way of watering. First lightly loosen the surface of the ground with a fork, then give a good soaking, and mulch with leaf soil, short manure or strawy litter. Liquid manure of some kind and not too strong may well follow the first soaking with clear water, and will be of much benefit to plants rooting in poor soil. Chrysanthemums can be potted readily from the open ground, but not from very hard and poor soil, nor are they of much service if allowed to become crooked. Stopping ought long since to have been completed

once or at the most twice being sufficient, or all that is advisable. Among summer-flowering varieties *La Petite Marie*, both white and yellow, are little gems, and *St. Mary* is still one of the best.—W. I. M.

A PROPOSED TRIP TO EGHAM.

LAST year an arrangement was made for a visit to Messrs. Cannell and Sons' nursery, Swanley, by members of the National Chrysanthemum Society with their friends, and the excursion proved such a pleasant one that Mr. Holmes was requested to plan a similar trip for the present season. This has been effected, and Baron Schröder having given his permission for the party to visit the gardens and houses at The Dell, Egham, the excursion has been fixed for Friday, August 24th. The party will assemble at the booking office, Waterloo Station, at 12.30 P.M. The train is timed to reach Egham station at 1.40, whence the visitors will proceed to The Dell, returning to tea luncheon at the "Angler's Rest Hotel" at 5 P.M. The return train leaves Egham at 8.30 P.M., due at Waterloo at 9.29 P.M. The cost, inclusive of railway fare and luncheon, will be 4s. 6d. each, and all desirous of joining the party should communicate with Mr. W. Holmes, Frampton Park Nursery, Hackney, by August 21st.

EVENTS OF THE WEEK.—To-day (Thursday) the Maidenhead, Aberdare, Ludlow, Abingdon, and Taunton Shows will be held. At Exeter the Summer Exhibition takes place on Friday, the 17th, and the Co-operative Society's Show at the Crystal Palace, on Saturday, the 18th inst. The Shrewsbury (two days) and Newcastle-on-Tyne (three days) Shows will be opened on Wednesday, the 22nd inst.—

— WE are informed that Mr. W. Pratt, Longleat Gardens, has recently been the recipient of a very HANDSOME PRESENT from the King of the Belgians, which takes the form of a breastpin set with diamonds and pearls surmounted with a gold crown, given in recognition of the attention tendered to His Majesty during the recent visit to Longleat.

— FROM Messrs. Dicksons of Chester come flowers of the hardy BORDER CARNATION *MRS. REYNOLDS HOLE*, which has been certificated and commended at several exhibitions. The flowers are of moderate size, good shape, and a bright terra cotta red tinged with orange. We recently saw a bed of the variety in which the plants were growing vigorously and flowering freely, proving that it is of good constitution, and the colour is a very popular one.

— WE regret to learn that Mr. ALEXANDER ROGER, who has been superintendent of Battersea Park for seventeen years, died on the 7th inst., at the age of sixty-two years, after a long illness. Mr. Roger passed a varied career as gardener in early life, and was appointed to the charge of Battersea Park in 1871, succeeding Mr. Gibson, who had laid out the greater portion of the Park. Several additions have been made and improvements effected since then, notably on the eastern side, which was rendered very picturesque, much taste being displayed in the management of the ground. The Park also was well kept, the carpet and sub-tropical bedding being arranged with especial skill. Mr. Roger leaves a widow and family.

— **WINTER SPINACH.**—"This vegetable," writes "H.," "finds favour in most gardening establishments, and in order to have a good supply when called for, a sowing should be made at once, and again in a week or ten days' time. The ground selected for the crop should be well exposed to the south, be manured, dug, trodden, and made level with a rake. Sow the seeds thinly in shallow drills at from 16 inches to 18 inches apart. The only after attention necessary is to thin the young plants to 6 or 8 inches apart in the rows as soon as they are large enough to handle, to keep them free from weeds, and to stir the soil between the rows with a Dutch hoe as much to keep down weeds as to accelerate growth in the plants. This operation should be attended to frequently from September to May."

— THE chief points to be attended to in TOMATO CULTURE OUT OF DOORS are to keep the shoots and leaves well thinned and pinched, as any approach to the crowding of these would contribute to failure. By attending to the process of thinning and stopping in due time, and keep-

ing the plants well supplied with water at the roots during ordinary summer weather, no disease will attack the plants, and good crops of wholesome fruit will be secured.—W.

— MR. W. H. DIVERS, Ketton Hall, Stamford, says:—"I have been awarded a certificate by the Liverpool Horticultural Society for the new green fleshed MELON KETTON GEM, raised by myself, and which your reporter spoke so highly of as being awarded the first prize at the Sefton Park Show on the 4th and 6th inst."

— THE WEATHER.—"B. D.," writing from Scotland, says:—"With occasional glimpses of sunshine, the weather continues gloomy, cold, and wet. A good deal of hay has been secured in better condition than was expected, but the prospect for harvest is far from bright. Heavy rains have laid the Wheat and Barley very much, and Beans are not filling. There is no appearance of ripening for weeks to come." In the South of England the weather during the past week has been very fine, bright, sunny, and warm—exactly what has been so long desired.

— THE schedule of the WARWICKSHIRE HORTICULTURAL SHOW, to be held at Rugby in conjunction with the Agricultural Show on Tuesday and Wednesday, September 4th and 5th, is just to hand. Fifty classes for plants, cut flowers, fruit, and vegetables, open to all exhibitors, are provided, fifty others being devoted to amateurs and cottagers. Substantial prizes are offered for plants, the three principal classes being for ten stove or greenhouse plants in flower, £7, £5, and £3; ten ornamental foliage plants, £5, £3, and £1 10s.; and for the best decoration for a conservatory, to cover a space not exceeding 20 feet by 12 feet, crescent shaped, £7, £4, and £2. The Hon. Sec. is Mr. Arthur Mason, 40, Albert Street, Rugby.

— "IN cold districts," says "H. W.," "the present is a good time to sow seeds of the most approved varieties of LETTUCES FOR WINTERING IN COLD PITS for transplanting early in spring. Ten days later will be soon enough to sow in warmer districts. These should be sown on a border having a south aspect in beds 4 feet wide, with an alley 1 foot between, covered lightly, and then be protected from the ravages of birds by placing a piece of small-meshed netting over the beds, supported by short forked sticks. As soon as the plants are large enough prick them out in a pit or frame in rows 3 inches asunder, and the same distance between the plants in the rows. The soil should be previously dusted with a mixture of soot and wood ashes to keep slugs away. Plants should be put out in the same manner and at the same distance apart in a dry warm border out of doors, where, during frosty weather, they can be protected with fern or straw in bad weather."

— THE monthly meeting of the NOTTS HORTICULTURAL AND BOTANICAL SOCIETY was held on the 9th inst. in the Arboretum rooms, when there was a large attendance of members and the general public. There were on view a good display of cut flowers, fruit, and vegetables, in addition to a miscellaneous collection of stove and greenhouse plants. Amongst the most noteworthy exhibitors of plants was Mr. Alfred Page, of Bulwell, who sent three magnificent pots of the beautiful *Eucharis amazonica*, which were carrying upwards of 300 developed flowers. The same gentleman contributed a choice collection of other plants, amongst which were several good Orchids. Mr. W. H. Farmer of Alexandra Park sent several good exhibits, a pair of baskets containing fine examples of *Hoya bella* mixed with Maidenhair Fern being very noticeable. Mr. W. F. M. Webb, The Park, had a pretty group of *Coleuses*, *Fuchsias*, &c., and Mr. Hallam, Sherwood Rise, some remarkably good Cockscombs. Amongst the other exhibitors was Messrs. J. R. Pearson & Sons, Chilwell, who staged a large and varied collection of herbaceous flowers, which was much admired. Mr. C. T. Cox had a good collection, including many stove flowers. Mr. Lockwood, Clarendon Road, had good *Selaginellas*, and Mr. J. Booth a fine flowering Orchid. Cut Roses were a leading feature, the principal exhibitors being Mr. Fouljambe, St. Ann's Well Road; Mr. T. B. Hallam, and Mr. R. Thurlby of the same place. Amongst the principal exhibitors of hardy fruit which was very fine, were Mr. E. W. Field, Aspley Hall; Mr. Edward Massey, and Mr. R. Halford, Magdala Road. Vegetables were also well shown by Mr. E. W. Field. The Judges were Messrs. Gadd, C. Pearson, Meadows, and Pownall.

— AT the ordinary weekly meeting of the members of the WAKEFIELD PAXTON SOCIETY, held at Councillor Lupton's, the "Saw Hotel," Councillor W. H. Milnes, the President, was in the chair, and

Mr. H. Oxley occupied the vice chair. Owing probably to the unfavourable weather, and to the fact that it was the Walton Flower Show, there was scarcely an average attendance of the members. Mr. J. Carter, nurseryman, of Cowick, near Snaith, and formerly gardener at Outwood Hall and Portobello House, near Wakefield, read an interesting and thoroughly practical paper on the growth of the Melon. He minutely detailed the mode to be adopted from the sowing of the seed to the fruiting period of the Melon, in order to cultivate it successfully in houses and frames. He also mentioned the best varieties, and gave much valuable advice and many useful hints. As the essayist had to return home by train shortly after nine o'clock there was not time for much discussion, but a few questions were put by Mr. Garnett and Mr. Oxley, and these were answered by the reader of the paper. On the motion of Mr. Garnett, seconded by Mr. Pye, Postmaster, a very hearty vote of thanks was accorded to Mr. Carter, who is one of the oldest members of the Society, for his valuable paper. Several new members were ballotted for, and after they had been duly elected, Mr. G. W. Fallas, one of the Honorary Secretaries, made a report with regard to the annual Window Garden Show promoted by the Society and held on the previous Saturday, from which it seemed that the entries were considerably larger than in any previous year, and, despite the bad weather, the Show attracted a numerous attendance of the public. Hearty votes of thanks were given to the officers of the Rifle Volunteers for the use of the Drill Shed, to the Mechanics' Institution for the use of their fountain, to the various ladies and gentlemen who exhibited plants and flowers not for competition, to those who had lent tables, stands, flags, and banners, &c., to the decorators, and to Messrs. Fallas and Garnett, the Honorary Secretaries, for their indefatigable efforts.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 14TH.

THE meeting of Fruit and Floral Committees at the Drill Hall, Westminster on Tuesday last was not well attended either by exhibitors or visitors, but the fine weather and the holiday season may account for their absence to some extent.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq., in the chair, and Messrs. W. Warren, R. D. Blackmore, G. W. Cummins, Jos. Cheal, John Lee, W. Marshall, A. H. Pearson, James Smith, and J. Wright. Mr. J. Southam, Orland, Southampton, a few years ago sent specimens of a seedling Apple, of which grafts were requested to be sent to Chiswick; this having been done they were established, and fruits now exhibited from the trees proved to be either identical with or slightly inferior to those of the Red Astrachan, brought for comparison from the Society's gardens. Mr. T. Banyard, Poplar Hill, Cambridge, sent a dish also bearing haulm of a dwarf Pea, with very large pods but too old. It was considered worthy of being grown at Chiswick, to be examined there in due season. Mr. J. Chambers, Westlake Nursery, Chiswick, sent fine and highly coloured Royal George Peaches, for which a cultural commendation was unanimously awarded. Messrs. J. Cheal & Sons sent a dish also bearing branches of Fay's Red Currant, an American variety, but very similar to the Red Cherry. Although the fruits were large, and a dish would show to advantage on the exhibition table, it was deemed inadvisable to grant any award that might induce persons to plant trees extensively for producing fruit for market. Mr. W. Roupell, Harvey Lodge, S.W., sent dessert Apples. Mr. Gladstone, Red Juneating and Early Harvest, all ripe and good, the first named especially so, and further, the fruits from trees to which soot and lime had been applied were decidedly the more highly coloured. Messrs. W. Lovel & Son, Driffield, sent a dish of the true Filbert Pine Strawberry, one of the best late varieties, for which a vote of thanks was awarded. Two Melons were sent for examination, but they were not superior to existing varieties.

Messrs. James Veitch & Sons exhibited a remarkable collection of Gooseberries, comprising a hundred dishes of the leading varieties, also cordon and pyramid Gooseberry trees in pots laden with fruit. A silver Banksian medal was recommended. Votes of thanks were accorded to Mr. J. Walker, Thame, for a collection of Gooseberries, Currants, and other fruits; also to Messrs. Paul & Son, Cheshunt, for several good dishes of Gooseberries.

White Transparent and White Astrachan Apples were exhibited from Chiswick, the former having been received from Russia some years ago, and though bearing some resemblance to the White Astrachan is larger and of better quality, the flesh being very juicy, tender, and sweet. Plums, Early Prolific and St. Etienne, also came from the Society's gardens, the former well known and good, the latter a greenish yellow companion, rather larger, and the tree an abundant bearer. Some Figs were also shown, Bourjasotte Grise being the richest in flavour.

Mr. D. Tallerman, of the Leadenham Market Cold Storage Company, attended the meeting, and addressed the Committee on the preservation of fruit. He stated that Strawberries had kept fresh and good in the cold chamber for a month, and Cherries placed in when wet a week ago were now dry and sound. Mr. Barron had inspected them, and was satisfied with the result. Mr. Tallerman thought further action should

be taken under the advice and inspection of a committee, which he would be willing to join, and give all facilities he could in conducting further experiments.

A Committee, consisting of Dr. Hogg, Messrs. John Lee, T. Francis Rivers, H. J. Veitch, J. Wright, J. Smith, J. Cheal, D. Tallerman, with Mr. A. Barron as Secretary, was appointed, and a vote of thanks conveyed to Mr. Tallerman for attending the meeting.

FLORAL COMMITTEE.—Present, G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. W. Wilks, J. Fraser, J. Walker, H. Hertst, W. Goldring, W. Holmes, C. Pilcher, H. Ballantine, J. Dominy, J. O'Brien, E. Hill, G. Paul, C. Noble, and Dr. M. T. Masters.

From the Royal Gardens, Kew, came flowers of *Pereskia Bleo*, large and soft pink, are of the best of the family; *Mucuna imbricata*, an East Indian climbing plant, with large Pea-shaped, dark, almost black, flowers; the graceful and charming *Littonia modesta*, bright orange, with narrow cirrhose leaves; and *Eucomis bicolor*, pale green, edged purple, and purple stamens. G. F. Wilson, Esq., Weybridge, sent a white flowered variety of *Maurandya*, raised from seed sent from the Sandwich Islands by Mr. Scott B. Wilson. The plant was exactly the same habit as the ordinary *M. Barclayana*, but the flowers pure white. The pretty little dwarf *Stenogaster concinna*, *Lilium superbum* varieties, *L. longiflorum*, and some pretty *Gentians* came from the same garden. M. S. Cooke, Esq., Coombe Bury Cottage, Kingston Hill (gardener, Mr. Cullimore), was awarded a vote of thanks for *Lelia elegans*, with two racemes of four and eight flowers each. G. C. Raphael, Esq., Castle Hill, Englefield Green, Staines (gardener, Mr. W. Swan), was accorded a vote of thanks for *Oncidium splendidum*, a pale form of the *O. tigrinum* type, *Cypripedium concolor* *Regnieri*, and *C. unicolor* of a pale yellow tint, and spotless. Mr. Cowley, gardener to F. G. Tautz, Esq., Studley House, Hammersmith, sent a plant of *Cypripedium* Charles Canham, the flower being large with broad purple tinted petals.

Mr. Gordon, Twickenham, exhibited a collection of *Iris Kämpferi* flowers, comprising some beautiful purple, blue, striped, reticulated, and parti-coloured varieties, a pure white one named *The Bride* being excellent. Flowers of the yellow and maroon dotted *Lilium Leichtlini* were also sent from the same nursery. Mr. C. Turner, Slough, showed a box of *Carnation* flowers, very fine examples of *Almira*, yellow with a few red streaks; *Dorothy*, salmon and red streaks; *Agnes Chambers*, yellow edged rose; *Coloured Beauty*, similar to *Dorothy*, but with rather more colour; *Annie Douglas*, sulphur streaked bright rose; and *Terra Cotta*, salmon buff, with a dull mauve edge, curious (vote of thanks). Mr. J. Charlesworth, Heaton Bradford, sent a plant of *Bifrenaria bicornuta*, the flowers small, ye low, the sepals and lip barred with brown, the petals dotted with a similar hue. A plant of *Odontoglossum Alexandræ heatoniense*, a pretty brown blotched variety on a white ground was also shown.

Messrs. H. Cannell & Sons, Swanley, showed some handsome double *Tuberous Begonias*—Mrs. F. Jenkins, pale yellow; Mrs. Cornwallis West, bronzy yellow; Mrs. Paget, dark yellow; Mrs. Hadden, pale rose, very large, and C. Showell, which was certificated (vote of thanks). Mr. J. Walker, Thame, Oxon, sent a box of cut blooms of *Rose La Biche*, a strong-growing and free-flowering variety, said to be useful throughout summer and late autumn. The flowers are pretty and neat in the bud stage, white, but when expanded are semi-double. It has been long grown as a pillar Rose.

Messrs. Paul & Son, Cheshunt, contributed a large and handsome group of *Roses*, hardy flowers, which nearly occupied one whole side of the central table. *Phlox decussata* *La Fille de l'Air* (vote of thanks), white with a pink eye, was also very fine. *Gaillardias* were good, *Geum coccineum plenum*, *Harpalum rigidum*, *Lilium longiflorum*, *Poppies*, *Phloxes*, and *Carnations* added much to the attraction of this important group (silver-gilt Banksian medal). Mr. W. Williams, Walcot Nursery, Ryde, exhibited miniature *White Clove*, about the size of a white Pink, and a buff yellow seedling *Carnation*, named *Jubilee* (vote of thanks). Mr. G. Davidson, Ammanford, Carmarthenshire, sent the large white *Lobelia* Miss Hope, and Mr. T. Williams, Devizes, had a plant of a blue and white *Lobelia*, said to be a sport from *Blue Beard*.

Mr. T. S. Ware, Tottenham, was adjudged a bronze Banksian medal for a beautiful group of hardy flowers, comprising a collection of early-flowering *Chrysanthemums*, the bright yellow *Precocité* being one of the best. *Gaillardias* were very handsome, *Phloxes*, Iceland *Poppies*, the blue *Pentstemon heterophylla* and *Cannas* were also notable. Mr. R. Dean, Ealing, exhibited a collection of *Phloxes*, *White Intermediate* and *Mauve Beauty* *Pyramidal Stocks*, with several pretty border *Carnations*, *Fair Maid* being a soft pink variety, and *White Lady*, pure white. (Vote of thanks.) Messrs. Cheal & Sons, Crawley, showed their patent wire flower support, recently noted in these pages, which was commended.

CERTIFICATED PLANTS.

Croton Aighurth Gem (R. P. Ker & Son, Liverpool).—A graceful narrow leaved variety of the interruptus type, the leaves drooping, bright red green and yellow, very handsome.

Begonia C. Showell (Cannell & Sons).—A grand double *Tuberous Begonia*, the flowers of excellent shape, symmetrical, the petals slightly undulated, full, and of a bright rose colour.

Carnation R. H. Elliott (Laing & Mather, Kelso).—A pleasing variety, the flower of moderate size, yellowish streaked rosy scarlet.

Papaver orientale *Blush Queen* (T. S. Ware).—Flowers large as the ordinary *P. orientale*, pale blush, with purplish black blotches at the base of the petals. It lasts well in flower.

ODONTOGLOSSUM MACULATUM.

THIS must be placed amongst the most useful of easily grown Orchids, and the woodcut (fig. 17) represents a specimen that well shows what can be done with the plant when it is properly treated. Varieties are numerous, and they differ greatly in merit, the one here depicted being in the style of the interesting *O. Humeanum*,

afford suitable quarters. The admission of dry hot air directly on to the leaves is injurious, but in the summer months it is well to afford all the ventilation that can safely be provided, and a moderate exposure to sun to mature the growths will assist the plants.—
ORCHIDIST.

THE WEATHER AND GARDEN CROPS.

IN response to our invitation last week numerous correspondents have obliged us with notes on the weather of June and July, with its effects on garden crops. A portion of these communications appear in the present issue, and we are reluctantly compelled to withhold many of equal interest until next week.

CHESHIRE.

THE months of June and July were unusually wet and cold for

FIG. 17.—ODONTOGLOSSUM MACULATUM.

which has been supposed to be a natural hybrid between *O. cordatum* and *O. Rossi*. The greenish brown sepals, the yellow brown dotted petals, and lip afford a peculiar combination of tints, wanting perhaps in the brightness some appreciate, but carefully arranged with other flowers they have a good appearance. One valuable character is the length of time the flowers last either cut or on the plant, and as growth is made at different seasons of the year a succession of flowers is obtained over a long period.

Odontoglossum maculatum will stand much rough treatment, but its demands are so small upon the attention of a cultivator that there is no excuse for neglect. A little good fibrous peat, plenty of sphagnum, a cool well ventilated position, and plenty of water from spring to autumn are the chief points to be noted. Any ordinary cool Orchid house will suit the plant, and during the summer a frame not much exposed to the sun and a moist base of ashes will

the time of the year, though the actual rainfall here we have not measured. The effects of the want of sunshine and cold are that the season is unusually late, and as a proof of this we have not yet cut a Vegetable Marrow nor gathered a dish of Runner or French Beans, when last year we were using them long ere this date. Potato crops are pretty good both in bulk and quality, though amongst the haulms there are indications of disease. The Pea crops have been good too, excepting the dwarf varieties, which have not done nearly so well as the taller ones. Ne Plus Ultra has grown to about 9 feet high, and a fine crop, giving complete satisfaction at the table. If we have fine weather throughout this month the season may be classed as fair, as the bulk of crops are good.

Amongst annuals Stocks and Asters are good; the former are better than last year, though the latter are scarcely so far advanced as to write with certainty on the comparison. I have grown the East Lothian Stocks for many years, and this season I may say they have been very

fine. Roses in the early part of the season were poor, with many of the petals damaged by insects, but now (August) the blooms are very good, *Général Jacqueminot* being conspicuous in its abundance of bloom. Bedding plants are unusually poor at this time, and if we have not a good autumn it will be one of the most unsuccessful of recent years.—ROBT. MACKELLAR, *The Gardens, Abney Hall, Chislehurst*.

HAMPSHIRE.

THE rainfall here at an altitude of 395 feet during the month of June was 3.31, as against 1.41 in June of last year. July produced 5.48 as against 0.26 of last year. Rain fell on fourteen days in June this year as against eight days last year in the same month. The largest quantity was 0.62 on the 27th June this year. In July there were nineteen wet days; the largest quantity collected was 1 inch on the 2nd of the present year. In July of last year the largest quantity was 0.11 on the 5th. The temperature reached 80° in the shade on six occasions only in June, the highest being 83° on the 24th. The lowest temperature registered was 42° during the night of the 17th. On ten nights only was the temperature above 50° during the month. July did not produce a single instance of the temperature going above 76°; this the highest on the 11th, while on fourteen occasions only did the heat reach over 70°, as against thirty-one times in 1887. The lowest temperature this year was 39° on the 9th, while on nine occasions the temperature was below 45°. During nineteen days the wind in a southward direction. It is known that in July we should have 497 hours of sunshine, but this year we had only 94½ hours. On sixteen occasions during June last year the temperature was 80° in the shade, while on three days it went over 90°. During July last year the temperature reached 80° twenty-six times. Nine nights only registered a heat below 52° during the month.

The heavy rainfall of the past month and low temperature with absence of sun have been much against the growth of outdoor crops, particularly vegetables, here on our heavy retentive soil. Broad Beans have scarcely podded at all, while Peas sown on the 9th of February were not ready to be gathered until the end of July, the variety being *Fortyfold*, generally such a good cropping sort. We shall not be able to pick French Beans outside yet for a fortnight. Tomatoes which were such a heavy crop in 1887 have not yet set a single fruit out of doors. Autumn Onions are badly diseased, they usually do well here. Spring-sown Onions look remarkably gross, and if dry sunny weather prevails the crops will be good yet. Early Cauliflowers have done very well indeed, while *Veitch's Autumn Giant* have not yet turned in, although sown in the autumn and wintered in frames. Potatoes are medium, and late sorts are a large crop, but except *Sutton's Seedling* are of bad quality, and are now much diseased. Early Peas sown in pots, planted out carefully, succeeded admirably; in fact without these we should have been without supplies for a long time. Broccoli and Winter Greens do not grow freely in this neighbourhood, there is much complaint of the plants being blind. Turnips have been unusually good this year, *Snowball* is the best variety.

Small fruits have done capitally, so have Cherries, both on the walls and in the orchards. Apples are only a fair crop, and very small as yet. Pears poor; Strawberries much below the usual standard, as many as 20 tons less being sent away from one station in a day, as a large quantity is grown in the neighbourhood to supply the London and other markets. Fruit decayed on the ground in quantities owing to the wet sunless weather.

Among bedding plants Tuberous Begonias are far the best plants. In spite of the adverse weather they make a splendid show, while Pelargoniums have scarcely a single perfect truss to show. Blue Lobelias appear to stand the weather fairly well. Some carpet-bedding plants, such as *Mesembryanthemum cordifolium variegatum*, make the best show this year. *Alternantheras* have made but little progress, the space not being yet filled. Perennials are best represented by Lobelia cardinalis, used as a bedding plant. This looks remarkably well. So do *Stenactis speciosa*, *Boeonia cordata*, Mule Pinks, Carnations, *Erigerons*, *Phloxes*, double and single *Delphiniums*, *Canterbury Bells*, *Centranthus ruber*, *Achilleas* of sorts, *Lychnis viscaria fl.-pl.*, *Aconitum Napellus*, *Chelone barbata*, while *Lilium candidum* has failed to develop a single presentable bloom, the foliage died first followed by the flowers. Single Dahlias have grown and flowered freely for some time now, and so have the Cactus varieties *Juarezii* and *Mrs. Hawkins*. Many of the perennials have grown out of character entirely—for instance, *Echinops Ritro* has grown 6 feet high, whereas it generally only grows 4 feet high. Amongst annuals *Zinnias* are a total failure, so are *African Marigolds*, *Dianthus*, annual *Chrysanthemums*, *Coreopsis*, and *Salpiglossis*, while *Asters* promise well. *Petunias* are fairly good, the same may be said of Iceland Poppies sown this year.

Hardy deciduous and evergreen flowering shrubs and trees bloomed remarkably well and have made much satisfactory growth. Particularly this applies to *Rhododendrons*, which are already forming plump flower buds. Conifers have grown well. The foliage of *Beeches*, *Limes*, *Elms*, &c., I have never seen looking better.—E. MOLYNEUX, *Swanmore Park Gardens, B. Waltham*.

THE rainfall for June and July at this place I append; 300 feet above sea, distance about six miles. June 4.23 inches, on the 26th 1 inch fell in an hour, from 9.45 A.M. to 10.45 A.M. Rain fell on fourteen days. In July 6.29 inches. The most registered for the preceding twenty-four hours was on the 8th, 1.45 inch; on the 3rd, 1.22 inch. Rain fell on seventeen days. Total rainfall for the two months 10.52 inches.

I append for comparison the monthly rainfall to date for this year. January, 1.63 inch; February, 1.00; March, 4.32; April, 1.73; May, 2.18; June, 4.23; July, 6.29; August to 11th, 1.03. Total, 22.41.—N. FULLER, *Gardener, Idsworth, Hornsea*.

LANCASHIRE.

THE weather during the months of June and July has been extraordinary. Rain has been frequent, and sunshine rare, we had but a few hours during some weeks. This has been most trying to late Grapes, and there has been a great difficulty in preventing "scalding;" in fact, with every care, we have lost more berries by this cause than altogether during the past ten years. With the exception of one or two bunches serious injury has not been done. The kind of weather we have had has been most trying to Cucumbers under glass. They have suffered severely when the sun has come out strongly; in fact, their foliage has been so void of substance, that they have quickly displayed signs of distress. To keep them going it has been necessary to take light instead of heavy crops from them. Large quantities of the young fruits have turned yellow when they should have swelled. Red spider and aphides have troubled us more on these plants than we before remember, while Broad Beans and Lettuces outside have been smothered with the latter.

Small fruits have done fairly well, but have been sadly deficient in flavour. The fruit of *Vicomtesse Hericart de Thury* Strawberry has stood the wet weather much better than we expected, for very few fruits decayed, while those of larger fruiting varieties decayed before they were ripe. Cherries have all cracked, but Morellos look well, and up to now we have not observed a cracked Gooseberry.

The wonder is that crops outside have done as well as they have. During the night of July 31st the thermometer fell to 34°, on a former occasion to 36°, several nights it was only 40°, while the highest day temperature of the 30th was only 55°. French Beans on early borders are practically a failure, for they are only just tuning in, and the plants have a stunted appearance. Those in the open quarters were nearly blown out of the ground in June, the foliage being broken and battered to such an extent that they looked wretched a few days afterwards. They have recovered and look promising now, but one named *Emerald Gem* has stood the trying season and looks healthier and more promising than either *Osborn's* or *Canadiah Wonder* sown at the same time. Peas were blown out of the stakes, and so damaged that they have not filled well. Potatoes are a light crop, and the haulms of nearly all the second earlies are fast dying; they have the appearance of being badly diseased, but no trace has yet been found amongst the tubers.

Amongst outdoor flowering plants Pansies and Violas, Musk (both the common and Harrison's) have continued to flower well. *Calceolarias* that were not in flower when they were planted are now in excellent condition. *Pentstemons* have shown a tendency to grow, and have flowered only fairly well. *Antirrhinums* seemed to have defied the elements, while *Candytuft*, *Mignonette*, and annual *Chrysanthemums* have never been better. Bedding *Pelargoniums* have surprised us by the way in which they have flowered, that is autumn-rooted plants. It was hot and dry when they were first put out, which ripened and hardened them well. Spring-struck plants have done nothing but grow. *Bicolors* during wet seasons have generally a weedy appearance, but *Crystal Palace Gem* is an exception, it has grown freely and coloured well. Roses have had a starved appearance, and the blooms have generally been deficient in size and colour, while hundreds decayed before they opened. They have grown well however, and now look promising to continue a supply of blooms over a much longer period than has been the case for years.—WM. BARDNEY, *Norris Green Gardens, West Derby, Liverpool*.

LEICESTERSHIRE.

THE weather during May was cold and dry, and June came in with rain which was much needed, as from March till June many of the farmers had to carry all the water to their cattle. The wind, which had been N.E. nearly all the spring, was southerly for two days; but the temperature was only a few degrees higher, and it returned to the N.E. again. From that quarter we have nearly all the rain. The thermometer registered as low as 40° on thirteen nights during June, twice 38°, once 36°, and once (June 30th) it was 34°. In some places it was quite a white frost. On eight different days the maximum temperature did not exceed 55°. On the 24th the thermometer rose to 76°, while on the 25th, 26th, and 27th, 79°, 82°, and 88°, when another change came, and on the morning of the 30th the thermometer registered 34°. The first week in July we had a little rain nearly every day, but the second week we had heavy rains every day, which continued, though not quite as heavy, during the following week, since which time the weather has been more favourable, and we have now (August 10th) beautiful summer weather. The last four days the thermometer has been above 80°. The spring and summer so far have not been very changeable. With a few exceptions it has been cold throughout, and vegetation has advanced steadily. Up to this time I think this summer is quite equal to the last, though widely different.

Potatoes were late coming in, but we have good crops of the earlies and free from disease. Peas have been and are still very good; our soil being rather light, the wet weather has suited them, and we have promise of good crops for at least another month. The wet has just suited the Celery, and at present we are quite free from the fly. Parsnips, Carrots, and all the Brassica tribe are now doing well. Onions have made an abundance of top, but no signs of bulbing at present. Broad Beans are good. Dwarf Beans have not done well, and are very late.

Scarlet Runners are late, but promising: we are just gathering our first dish.

Roses were very promising in bud, but the wet prevented quite half of them from expanding, more especially such light sorts as Miss Harsard. Phloxes and Madame Desgrange Chrysanthemum are unusually early this year: some of the latter are quite expanded. Dahlias are late, the cold prevented them from starting into growth. Delphiniums, Aquilegias, Sweet Williams, Sweet Peas, Pansies, and Violas have all done well. Calceolarias usually do well here, but have gone off badly this summer. Pelargoniums, Petunias, and Coleuses, have not succeeded so far, but are looking better now. Apples (except Keswicks) are very light this year, as also are Apricots, Plums, and Pears. There were many blooms, which set well but dropped soon afterwards, owing, I believe, to last summer's drought. Strawberries were quite a failure, another cause of the dry summer last year. Gooseberries and Currants, Raspberries, and Cherries are heavy crops.—J. L., *Leicester*.

NORFOLK.

THE rainfall here for July was 4.80 inches. Bylaugh Gardens are elevated, standing much above the surrounding country, 130 feet above sea level. On a sandy gravel the rains have been more of a benefit than otherwise. The Park and surroundings, usually scorched at this season, look lovely, the trees especially a mass of heavy green foliage. The flower beds have been poor, but the plants grew and are looking well now. I was not able to get many Strawberries for preserving, though we had a heavy crop. With the exception of a little hay spoilt on the home farm, I know of nothing injured. It has been, on the whole, a fine time for this light sandy soil. My vegetable crops are enormous. No mildew. Early Potatoes all up with no disease. Late ones I grow on the farm, putting them with the root crop. The land is farmed on the four-course system, so they never occupy the same land, and no disease is heard of. Onions are fine, autumn ones now ripening, spring-sown about half grown. Other vegetables, Peas and Beans, look equally well. Bylaugh is about the centre of Norfolk, six miles from East Dereham.

As to temperature, our maximum was 73° on the 20th. On three nights, July 1st, 7th, and 31st, the minimum was 32°, quite a white frost on the low lying meadows; it did no harm, slight early and late frosts seldom do here, though French Beans and some few other things hung their leaves a little.—A. FENN, *Bylaugh Gardens, East Dereham*.

NOTTINGHAMSHIRE.

THE wet, cold, and sunless weather which characterised June and July, and at which I have, with the rest of Britons, growled—ungrateful sinners!—has come to me, I am constrained to confess, full of benedictions. I have forgotten the frowns of June and July in the smiles of August. My water cisterns were empty, they are now full. My garden was gasping for rain, and almost refusing to move on; it is now full and plenteous with all manner of good things. The ladies get baskets and baskets of flowers daily, and plenty of fruit, and the cook is smiling and satisfied; what more can a gardener want? I am not a scientific measurer of the rainfall, nor a precise note-keeper of the weather. I go by my feelings, and as my feelings are only feelings, general in their tendencies, and perhaps slightly sentimental—an odd confession that for a man of fifty-six to make—they are not worthy of being recorded in a professional and scientific chronicle of garden events and meteorological influences. Amongst flowers herbaceous borders are wild with luxuriant growth, many of the plants have done excellently, nearly all well. Delphiniums surely never was so grand, and Phloxes promise great things. Roses have given occasional blooms of great glory and beauty, though many have died prematurely. The bedding out is late, and now there is a disposition to excess of leaf growth rather than flowers on flowering plants, but the carpet bedders have been improved by the past wet and present sun. Zinnias, Phlox Drummondii, and such like, are very backward, but picking up now. Beds of Petunias are going on finely; they had a struggle for it through June and July.

In the fruit garden Strawberries have been a failure, a paucity of flower stems, the result of the drought last year, and the wet spoiling those that did flower. If it had not been for Black Prince and Vicomtesse Hericart de Thury we should have been in a very poor way indeed. These kept us going for table consumption and garden picking and eating, and that only. Bush fruit are grand, Currants never finer, Blacks especially so. Pears will be a fair crop and general. Apples are only middling, rather below the average, and the winter sorts lowest of all. It is not a Caldwell year with us at any rate, and we rely on this variety for chief winter supply. Plums are scarce; Rivers' Early Prolific and Victoria are the two that are distinguishing themselves. I believe I am satisfied with everything in the kitchen garden. The assessment of the garden crops, when we come to sum up, is largely on the side of blessings however, and in the present sunshine of August who shall, who can, ungratefully murmur?—N. H. POWNALL, *Lenton Hall Gardens, Nottingham*.

THE total rainfall for June and July was 6.28 inches, sunshine 204 hours. We had nine sunless days in June and six in July. Rain fell on seventeen days in June and twenty-one in July. Vegetation quite fourteen days late; the first June in twenty years we have not gathered Strawberries. Some quarters have not fruited at all, others a fair average crop. Currants, Raspberries, Apples, Peaches (outside) very abundant. Cherries fair, Plums, Apricots, and Pears poor crops. Peas and Beans late and not good, Potatoes heavy crops, but wanting sun-

shine and dry weather. Of Roses we shall have a late long season, the dark sorts open better than paler colours. Most herbaceous flowers have done well, and the flowers lasted longer than in finer seasons. In bedding plants Pelargoniums have all their flowers washed off or decayed, whilst Tuberous Begonias are rather late, but good, and do not appear to have suffered from the damp cold weather. Stocks, Asters, and Zinnias are doing fairly well.—JOSEPH MALLENDER, *Hodsock Priory Gardens, Worksop*.

RUTLANDSHIRE.

JUNE was very changeable, but mostly dull and showery. We had only four bright sunny days during the month. We had thunderstorms five times, but not very heavy. The following observations are taken according to Symons' rules with instruments registered and certificated at Kew. We are 130 feet above sea level. June, barometer (not corrected to sea level): highest, 30.30° on 19th and 23rd; lowest, 29.55° on 20th. Average height of readings (9 A.M.), 29.99°. Thermometer highest in shade, 84° on 26th; lowest, 38° on 14th. Mean temperature of the whole month, 58.30°; lowest on grass, 35° on 14th. Total rainfall, 1.55 inch; greatest amount in twenty-four hours, 0.51 inch on 20th. Rain was recorded on eighteen days.

July was very wet and dull, not one bright day during the month. Temperature generally low, very little sunshine, and frequent showers. Barometer: highest, 30.15° on the 13th; lowest, 29.48° on 3rd. Average height of readings at 9 A.M., 29.69°. Thermometer: highest in shade, 73° on 19th; lowest, 40° on the 1st. Mean temperature of the whole month, 57.39°; lowest on grass, 34° on the 1st. Total rainfall, 4.14 inches; greatest amount in twenty-four hours, 0.71 inch on the 2nd. Rain was recorded on twenty-three days. We had a very heavy thunderstorm with hail on 4th, when 0.21 inch of rain was recorded in about twenty minutes.

Taking all things into consideration this has been a good season for these gardens, which are naturally dry and well drained, and the soil is full of small limestone, which have a very bad effect in a dry season. Roses flowered freely, but so much wet caused many of the flowers to decay almost as soon as they opened. Bedding plants have not made much progress since planting out, and Pelargoniums have very little flower on them, dwarf Tropæolums and Lobelia making the most show at present. Tender bedding plants are smaller than when first planted out. Our mixed borders have succeeded much better, and are much preferred to ordinary flower beds. Annuals.—The following have flowered well:—Bartonia, Nemophila, Leptosiphon, Clarkia, Erysimum, Godetia, Delphiniums, Sweet Peas, Centaurea cyanus, Linum grandiflorum, Schizanthus, Malope grandiflora, Eutoca viscidula, Collinsia, Convolvulus minor, Chrysanthemum segetum, Phacelia campanularia, Xeranthemum, &c. Perennials also have been very gay, especially Papaver bracteosum, early Phloxes, Delphiniums, Iris germanica, Spanish Iris, Veronica rupestris, Pyrethrums, Monardas, Campanulas turbinata and persicifolia alba.

Among other plants Dahlias and Sunflowers are very late this season. Lilliums, especially L. candidum, have not flowered so well as usual, owing I presume to the dry weather last season. Vegetables have grown freely, and are mostly good crops. Peas have been a long time filling, and are not so well flavoured as usual; they are also nearly twice their average height. French Beans and Scarlet Runners are very late; we have not yet (August 10th) gathered any outside. Tomatoes outdoors are a poor crop; by sowing early and getting large plants we have been able to gather a few fruits.

Early Potatoes are a heavy crop, but disease showed itself in the tops August 8th; we have none in the tubers at present, and they will be dug up as soon as possible, well dried, and stored in a cool place. Late Potatoes look well and have no disease at present. Snowdrop and Magnum Bonum are our favourites for autumn and winter use. Strawberries have been very scarce; owing to the dry season last year they did not make their growth soon enough. Currants, Gooseberries, and Raspberries, heavy crops and good here, but some growers complain of their lacking flavour. Apples are a medium crop, Pears thin crop, Plums very few, Cherries abundant, Peaches and Apricots very few. Many of the fruit trees were badly eaten by caterpillars early in the season, but aphides have not been troublesome.—W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

SUSSEX.

I HAVE no means of ascertaining the exact amount of rainfall, but from the first week in June to the first week in August it rained more or less every day or night, with much thunder and no sun for days, together with more wind than usual at this time of the year, and very cold nights. Everything is fully three weeks later than usual.

Among kitchen garden crops, early Turnips have been good, Cabbages and Cauliflowers are abundant. Peas have all grown strong and taller than usual, but have cropped well, though some sorts have not filled well, owing, I presume, to so much wet at flowering time. Onions are first rate though very late. Amongst Potatoes Early Rose, Ashleaf, and other early kinds yielded abundantly of large sound tubers, but too much wet spoiled their flavour; they were free from disease. Not so with midseason and late sorts, for they are badly affected. The disease was first noticed the last week in July upon a batch of Schoolmaster, in a few days it spread to all other sorts grown, and the haulm is nearly all dead. Carrots and Parsnips good; Vegetable Marrows good but late. Ridge Cucumbers later still, too cold for them. Kidney Beans and Scarlet Runners late but good crops. Tomatoes outdoors growing strong, but no fruit set, want sun and warm nights.

Fruits—Strawberries a fair crop, ripened slowly and much fruit

decayed through wet. Gooseberries, Currants, and Raspberries an abundant crop. Peaches and Apricots none. Pears on standard trees are a failure, but on walls a good crop. Apples on large old trees not a third of a crop; young pyramid trees have the advantage and have a fair crop. We had some severe frosts throughout May and these escaped. Cherries a good crop but spoiled by the wet. Plums on standards no crop, and the trees on walls have very few. Medlars and Walnuts a good crop. Fig trees not much affected by the drought last summer, and this year carry no fruit, with the exception of two large trees in a sheltered and shady position; these have a good crop.

Coming now to flowers, I am sorry to say that those we have taken most pains with, I mean the ordinary bedding Pelargoniums and other bedding plants, are most unsatisfactory; they grow but do not flower, and are not healthy looking. Clearly the excessive wet and cold nights have been against them, and had I not planted out a lot of annuals my cut flower supply would have been short. Stocks, Mignonette, Nemophilas, Dianthus, Candytuft, Convolvulus, Sweet Peas, and several others have kept me going and made the garden gay, and so far have put the bedding Pelargoniums in a third-rate place. Among perennials Campanulas, Delphiniums, Antirrhinums, Sweet Williams, and many other similar things have been a great help. Roses have grown strong, but through wind and wet half the flowers did not open.—T. RECORD.

THE rainfall here in mid-Sussex during the past two months was—June 3.91 inches in sixteen days, July 5.03 inches in twenty-two days—total 8.94 inches. The average of fourteen stations in various parts of the county was 5.23 inches. The heaviest fall in twenty-four hours occurred at Hastings on the 19th July, when 2.31 inches was registered. The heaviest fall for July at any station was 7.30 inches at Singleton. The season all through has been quite as remarkable for the want of sun as for the quantity of rain. Crops are very late. Strawberries swelled and yielded well, but were soft and flavourless, and much of the crop rotted on the plants. The same may be said of other soft fruits. There are a few Pears, but Apples are extremely scarce in this part of the county. Onions and Runner Beans have suffered most—the former only beginning to swell out, the latter falling off. We have lifted our early kidney Potatoes, having pulled the top out as soon as the blight made its appearance, and have them sound and dry; but we were not so fortunate with Snowflakes, they having been a few days longer in the ground. Since the 5th inst. we have had fine clear hot days, the thermometer above 80° every day.—R. INGLIS, *Cuckfield*.

WESTMORELAND.

THE rainfall for June here was 1.29 inches, rain falling on nine days. The highest and lowest temperatures were 80° and 31°, the former on the 26th, the latter on the 24th. The thermometer of a night registered very low for the greater part of the month, quite retarding growth. In fruit and vegetables, and tender bedding plants also, suffered very much during the month, especially Iresine and Alternanthera, from the low temperature and cold east winds. Our rainfall for July was 6.04 inches, rain falling on nineteen days. The highest and lowest temperatures were 62° and 32°, the former on the 4th, the latter on the 1st. The month throughout, with the exception of a few days at the early part, was very wet and showery, with thunder at times.

Our early Potatoes are lifting well, with no trace of disease at present. Later sorts are also looking well; the haulm, owing to so much rain, has made an extraordinary growth, but is very healthy. All fruit crops are very late, and some kinds quite a failure. Peas are filling very slowly, and French Beans, I am afraid, will be no good, the weather quite retarding their growth. All flowering shrubs here have done well this season, no doubt owing to the hot dry summer of last year, which was the means of ripening the wood thoroughly. I find the Begonias most satisfactory as bedding plants in wet weather here.—F. CLARKE, *Lowther Castle Gardens, Penrith*.

WILTSHIRE.

JUNE and July of the present year will rank among the wettest and coldest summer months we have had during the last forty years. The only way in which these unfavourable conditions affected the kitchen garden crops is in lateness of turning in, the quantity and quality of the produce having been everything that could be desired. We have had, and still have, an abundance of Peas and Cauliflowers of the best description, the former having been sown and planted (out of pots) in rows running north and south at from 6 to 8 feet apart, with a good mulching of decayed manure on each side, and from two to three rows of Cauliflowers between. One good effect of the rainy and sunless weather throughout the month of July is that Peas have kept much longer in bearing than is the case during an ordinary summer. Sutton's Royal Jubilee is a grand Pea, being a prodigious cropper, the pods containing from nine to twelve large and well-flavoured peas, each being large and handsome. As an exhibition and all-round good Pea it has no rival here. The effect of the cold and rain on outdoor flowering and foliage plants in the flower garden is very marked. The only plant which is really flourishing is the Viola. Beds of silver and golden-leaved Pelargoniums, intermixed with Blue Perfection and Golden Queen Viola, are everything that could be desired. It is truly a wet summer plant. Lobelia pumila magnifica, and Ageratum Tom Thumb, a very dwarf growing compact variety, are, since a favourable change in the weather has taken place, now masses of deep blue and mauve. Beds of Verbenas, Calecolaria amplexicaulis, and tuberous-rooted Begonias are also very effective. Roses, both on standards and on their own roots pegged down

in beds, have suffered considerably in consequence of so much cold and rain, but the present condition of the trees augurs well for a good autumn display.—H. W. WARD, *Longford Castle Gardens, Salisbury*.

WORCESTERSHIRE.

JUNE and July of the present year will be long remembered, not only for the heavy rainfall, but also for many days in succession without the least sunshine, and the extremely cold nights, forming a striking contrast to the same months last year. The rainfall for June as registered in these gardens was 1.84, rain falling on thirteen days; wettest day, 27th, 0.50. For July it was much heavier, rain fell on no less than twenty-two days; wettest day 23rd, when 0.76 fell. Total for the month, 5.22.

The heavy rainfall, together with dull cold weather, has caused many disappointments, especially so with the Strawberry crops, which suffered greatly from damp and the attacks of slugs. On some lands Broccoli and Brussels Sprouts have grown to an enormous size, and should a severe winter follow, I am afraid we shall hear many accounts of these winter vegetables being cut down. The losses will be greatest where planting has been done on rich and newly dug ground, showing once more the great evil of this. Where the iron bar had to be used the growth made was slower and naturally more consolidated, and will be much better able to stand severe weather later on.

In general the weather has been greatly against most outdoor flowering plants, but it sometimes happens that a wet season up to a certain point suits some flower gardens better than a dry one. Such I find the case here, and though many of the Pelargoniums are dashed with the rains, a few bright warm days would dispel this appearance, and the garden would look much better than last season. The following have grown and stood proof against the rain: Ageratums, Pansies, Lobelia, R. Fish Pelargoniums, Iresine, &c. Of annuals, perhaps the best are Mignonette, Zinnias, Candytuft, Helichrysums, &c. Petunias and Nasturtiums, though planted extensively, have failed, producing nothing but growth, especially the former.

The herbaceous borders have been remarkably gay, Phloxes producing an abundance of bloom ever since June, and will continue for some time. The Lychnis have proved valuable and very showy, especially L. Viscaria and L. chalcidonica; the latter at the present time is quite conspicuous with its scarlet flowers. Helenium pumilum is one mass of rich yellow flowers, growing beside the above Lychnis. All the Spiraeas have done well, this season just suiting them, while such graceful plants as Montbretia Pottsi and Sparaxis pulcherrima are producing finer spikes than I ever remember seeing before. Campanula Hosti has been very good indeed this season. In fact, in seasons like the present, or at any time, I consider more pleasure can be derived from a good collection of herbaceous plants than can be found in any ordinary terrace gardens.—R. PARKER, *Impney Gardens, Droitwich*.

YORKSHIRE.

IN Sheffield the weather throughout June and July has been almost uninterruptedly dull, cold, and wet, wind continuously in the north-west. Very few days occurred on which rain did not fall, and very few upon which we had sunshine.

All garden crops are exceedingly late, more so than in any previous season within my memory. We are only now (August 11th) commencing to gather midseason Peas sown in March. None, excepting the earliest varieties of Potatoes in warm positions, are yet ready for digging. Strawberries just in, midseason, differing much as to sorts. James Veitch, a heavy crop of large fruit, but more than half decayed; Black Prince, good crop, fairly sound; Vicomtesse, President, and Sir Joseph Paxton mostly barren. Gooseberries, Currants, and Raspberries, heavy crops, now ripening. Jargonelle Pears, very heavy crops; other varieties a fair average. Apples a small crop; Plums likewise. Kitchen garden crops promising to be fairly good, but extremely late. No Potato disease yet apparent.

Bedding plants have made little growth and less flowers. Hardy and half-hardy annuals have grown fairly well, but are only just now opening their first flowers. Perennials have grown strongly, but have only made a poor display, their flowers being spoilt by continued rains. Carnations are not yet in flower, will not be so before the end of this month. Chrysanthemums generally look well and very promising. The season on the whole has been the most difficult and unproductive one to gardeners.—W. K. WOODCOCK, *Oakbrook Gardens, Sheffield*.

THE contrast between the two months of June and July of last year and the same months of the present year are strikingly brought out by a few figures, furnished by a correspondent in a daily contemporary.

In the two months of June and July of last year there were recorded at the Royal Observatory, Greenwich, 507 hours of bright sunshine; in the same months of this year only 227 hours, the average being 316½ hours. Last year out of 61 days there were 43 on which more than six hours of sunshine were registered; this year there were only 15 such days. The days without sunshine were correspondingly 3 and 12. Last year only 43 per cent. of the sky was on the average covered by cloud, this year the average was 82 per cent. We have to go back to 1879 and 1860 to find years correspondingly cloudy, the percentage of cloud being in both years 81, and both being years remembered by agriculturists. Then as regards rain. In the months of June and July of last year the rainfall in all amounted only to 2.52 inches; in the present year this was 10.10 inches; the average being 4.37 inches. In no year since the establish-

ment of official record (1841) has the latter amount been at all equalled. The greatest falls occurred in 1853, 1860, and 1879, when the amounts registered were respectively 8.23 inches, 8.60 inches, and 8.01 inches. The amount for the present year is of course increased by the unusual and excessive rain of July 30th, when 2 inches of rain fell within the short space of four hours, causing the floods and consequent damage of which we have heard so much. In June and July last year rain fell only on three days and ten days respectively; there being 26 days (June 6th to July 4th) absolutely without rain. In the same months of this year rain fell respectively on 15 days and 26 days. That is to say, out of 61 days rain fell last year on 13 days, and this year on 41 days.

A few words now on temperature. The mean temperature of the month of June last year was 60.9°, or 1.1° above the average. This year it was 58.3°, or 1.5° below the average. That of July last year was 66.5°, or 3.9° above the average. This year it was 57.9°, or 4.7° below the average, and no less than 8.6° below the value for last year. In June and July of last year the temperature rose above 80° on twenty-one days; in the same months of this year only on three days—never, indeed, reaching 80° on any one day in July, the highest record for this month being 74°. July 11th and 12th of this year will be long remembered, the highest temperature reached on these days being 55° and 54° respectively: the mean temperature of the same days being respectively 15° and 13½° below the average.

These remarks apply, of course, primarily to the London district, although in general applicable to a larger extent of country. The figures given will show how extreme, so far have been the meteorological conditions of the present summer, and how completely in contrast with the fine weather of the corresponding portion of last year.

THE ROMANCE OF SEED-SOWING.

(Continued from page 126.)

II.—WINDS.—In many ways we see the action of this second agent. The simplest cases are those where the seeds (or their equivalents) are infinitesimally small, and of exceeding lightness. Thus, the spores of Fungi, Lichens, Mosses, and Ferns are easily carried by the wind to distant places; and so the members of some of the above named orders have an almost world-wide range. Some seeds of flowering plants are also light enough to be thus transported, or else they have some mechanical contrivance to render them so. One of our little Corn Salads (*Valerianella auricula*), whose fruit contains three cells, develops only one seed, the remaining two empty cells acting as a kind of balloon to the fruit, and most likely facilitating their movement by the wind. Then, again, there are seeds which are flat and very thin. Those of Yellow Rattle, a parasite on Meadow Grasses, afford an example. The wind shakes them out of their bladder-like capsule at ripening time, and carries them to a distance, where they find a congenial resting-place.

Coming to more familiar and more easily seen contrivances we find the winged fruits and seeds known to most of us. Among winged fruits we have the keys or doubly winged fruits of Sycamore and Maple, the single one of Ash, and the well-known winged nuts (so called) of Birch and Elm, those of the latter covering the roads in April and early May. When the winged fruit is detached from the tree it falls slowly with a rotatory motion, and the wind, if enough be present, is sure to catch it and bear it away. Lime has no winged fruit, but the long, narrow bract at the base of the bunch of fruits serves the purpose. Watch a bunch of Lime fruit falling, and note that the fruits hang lowmost, the bract catching the wind and carrying the whole mass away—very often to some distance. Among plants also we find instances of winged fruits, as in Dock, Parsnip, and Penny Cress, the latter being, like others of its order, a winged pod or pouch containing the seeds. In the case of Pines it is the seed which is winged—i.e., it carries with it a portion of the scale to which it was formerly attached. So the tiny seeds of *Arbor Vitæ* and Cypress in our gardens are surrounded by a thin membranous wing; equally provided are those of the beautiful Trumpet Creeper, while the seeds of some Begonias are so delicately winged that they describe a series of circles in the air, hovering, so to speak, before they finally settle. There is one instance of a wind-wafted fruit which, although not winged, I may name here. I refer to the "Rose of Jericho," a pod-bearing annual found in Syria and Egypt. Its pods, when dry, curl themselves up into a ball, and are driven, it may be, for miles along the ground by the wind until they happen on a damp place; there they stick, uncurl, open, and deposit their seeds. There is another case: a kind of Grass, in which the whole inflorescence, in the shape of a large round head, gets driven along the sands of Australia until it finds some moist spot where the plant can again take root and let fall its seeds.

Still more complicated and beautiful than the wings already seen are the tufts of down seen on many fruits and seeds, and they serve a similar purpose. This down, which forms Dandelion "clocks" and Thistle "blows," consists either of simple hairs or those provided with a feathery arrangement. It may be found attached to either the fruit or the seed. In the latter it may cover only a part of the surface, or it may entirely envelope the seed. A tuft of hairs developed from the seed is usually called a coma, from a Latin word signifying "hair." As one example of such seeds we may select Willow Herb, whose rosy flowers fringe our river banks and ditches—plants almost always found in wet or marshy districts. Each seed is tufted with silky hairs, and

the opening pod, containing several of these, is a very beautiful object. We are all familiar with the cotton-like hairs that show the presence of the seeds on the numerous kinds of Willow trees in early spring or summer. Here the seed nestles amid an almost perfect envelope of hairs. The *Asclepias*, or American Milkweed, has seeds tufted at one end like those of our own Willow Herb. The cotton of commerce consists of long, hair-like cells from the seeds of *Gossypium*, the Cotton plant, one of the Malvaceæ, or Mallow order. Each thread is really a cylindrical cell, often very long, which, when dried, flattens out and twists spirally. By this peculiar outline cotton can always be detected under the microscope.

When the hairs form a tuft on the fruit, we speak of them collectively as a pappus, from a classical word signifying "an old man," in allusion to the grey colour. The ripe carpels or fruits of Pasque-flower *Anemone* and of wild *Clematis* are furnished with a feathery tail, which is in reality the long style covered with silky hairs. The long, feathered, graceful fruits of *Clematis* festoon our hedges in autumn, and are known popularly as Old Man's Beard or Traveller's Joy, and are among the most lovely of our country sights. In the Red Valerian of our gardens, now wild in many places, the calyx unrolls, after flowering, in the shape of a feathery cap for the fruit, which can thus be easily carried about by the wind. If you examine a single fruit from the thick, dark-brown spike of Reed Mace or Bulrush (*Typha*), you will see that it ends below in a very delicate stalk, around which, at three or four different places, arise a series of circles of fine silvery hairs, which support the tiny fruit in the air. The softness of the spike is due to the presence of multitudes of fruits, each provided with these hair circles.

The Cotton Grass of our moors is another example. It is not a true Grass at all, but is the genus *Eriophorum*, belonging to the Cyperaceæ, or Sedges. Its fruits have a tuft of long, silky hairs springing from the base, and we often see a marshy landscape white with thousands of these hair-covered fruits.

The pappus as an air-floating device, however, reaches the climax of beauty and adaptation in the Compositæ, the order including Thistle, Dandelion, and very many other plants. Examine a head of Dandelion early in its history, and you see nothing of any pappus; but look at it later on, and you will see in the place of the many florets that made up the so-called "flower" a spherical collection of beautiful hairs which form the "clock" of the children. Each single fruit is prolonged above into a long stalk or beak (very much longer than the fruit itself), at the top of which is a close-set circle of delicate hairs arranged laterally, so as to form a kind of parachute, concave above. This parachute bears up the fruit and acts as a sail for it, and being by far the lighter end of the whole, causes the fruit to fall to the ground in the best position for its burial—namely, with the fruit itself downward. Most assuredly this wonderful contrivance for dispersing the seeds is the reason why Dandelion is as common as it is. "A common weed!" we say. Exactly; and it is a common weed because it is a highly adapted type, as Grant Allen tells us.

In the Hawkweeds—relations of Dandelion—the pappus is not raised on a beak, but is close down on the fruit, and is not so widely expanded, being more funnel-shaped. In Dandelion and Hawkweed the hairs are simple; but in the *Thrinicia* of our lawns (which some people will call Dandelion, but which is only a near relative), they are every one feathered. This is carried to the furthest point in *Tragopogon*, or Goat's Beard, called "John Go-to-bed-at-noon" by country folk, because it closes at mid-day. Here the hairs are not only feathery, but the feathery branches interlace all round the circle, so as to form a very powerful propeller under the influence of a breeze. All these contrivances, whether found on fruit or seed, are evidently developed by natural selection, in order to the better dispersion of the life-containing germ.—H. W. S. WORSLEY BENISON, F.L.S. (in the *Journal of Microscopy*).

(To be continued.)

HORTICULTURAL SHOWS.

FROME.—AUGUST 6TH.

THIS was a decided success, and that too in spite of rather unfavourable weather. In the plant tent especially there was a marked all-round improvement observable, nothing but a few well-trained specimen flowering plants being wanted to make the exhibition equal to any held in Somerset and surrounding counties.

The principal prizes were offered for banks of plants arranged on a space 12 feet by 6 feet. Of these there were no fewer than five competitors. Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, was placed first with a rather heavy arrangement, which included numbers of choice Crotons, fine Palms, several large and well-flowered *Eucharis amazonica*, Ferns, and other plants. The second prize was awarded to Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, for a much lighter arrangement, but which was scarcely imposing enough at the back. The bank was largely composed of elegant well-coloured Crotons, Pandanus, Dracenas, Palms, with *Lilium auratum*, *Paneratium*, Orchids, and Tuberous Begonias springing out of a groundwork of Maidenhair Fern. The third prize was well won by Mr. E. Brown, gardener to C. Baily, Esq., Frome, and very creditable groups were also arranged by Mr. Phillips, gardener to John Baily, Esq., Fairlawn, Frome, and Mr. S. Andrews, gardener to A. G. Hayman, Esq., Hapsford House, Frome. Mr. Pratt was placed first for six fine-foliaged plants, among which was a very fine *Latania borbonica*, the second prize going to Mr. Iggulden.

for smaller, but better matched Palms and Crotons. Mr. Brown took the first prize for a single specimen fine-foliaged plant with a good *Cycas revoluta*, Mr. Pratt being second. There was only one entry in the class for six flowering plants, this being by Mr. G. Tucker, gardener to Major Clarke, Trowbridge, who was rightly awarded the first prize. Among these were good plants of *Erica grandiflora alba*, *Allamanda Hendersoni*, *Dipladenia amabilis*, and *Statice profusa*.

In the class for four Orchids Mr. G. Pym, gardener to Mrs. Gouldsmith, Trowbridge, was first with strong well-flowered plants of *Cattleya labiata*, *Cattleya Loddigesi*, *Odontoglossum Alexandrae*, and *Cattleya crispa*. Mr. Iggulden was second for smaller plants, some of the flowers being past their best. There were two groups of six Fuchsias, both being highly creditable to the exhibitors. Mr. Brown was well first for specimens 7 feet high and beautifully flowered, the second prize going to Mr. Edwards, gardener to J. D. Knight, Esq., Frome. *Gloxinias* were also staged much better and in greater numbers than usual. Mr. Edwards was first for fine plants. The class for six Tuberous Begonias was well filled, and in this Mr. W. Bull, gardener to Captain Tucker, Keyford House, Frome, took the lead with compact, beautifully flowered plants of superior varieties. This exhibitor was also well first for six trained Zonal Pelargoniums and for six Coleuses, the competition being good in each instance. The collections of Ferns were quite a feature in the principal plant tent, the first and second prize groups of twelve varieties being nearly of equal merit and very fresh and good. Mr. G. Tucker was placed first, his best being Gold and Silver Gymnogrammas, *Adiantum cuneatum*, *gracillimum*, and *Asplenium Nidus-Avis*. Mr. E. Brown was second, having among others capital plants of *Adiantum farleyense*, *gracillimum*, *grandiceps*, and *Dicksonia antaretica*. Mr. Edwards was third. Mr. E. Wilcox, gardener to Mrs. Sinkins, Portway House, Frome, was first for six Ferns, Mr. J. Weston, gardener to the Rev. C. C. Layard, Bath, second, and Mr. W. Bull third.

Cut flowers were very well shown, the Roses being unusually good for the time of year. The best twenty-four distinct varieties were staged by Messrs. Keynes, Williams & Co., Salisbury, their stands including fine massive and well-coloured blooms of *Merville de Lyon*, *Ulrich Brunner*, *Marie Verdier*, *Boieldieu*, *Alfred Colomb*, *La France*, *J. S. Mill*, *Alphonse Soupert*, *A. K. Williams*, *Mrs. J. Laing*, *Madame Lambard*, *C. Lefebvre*, *Jean Soupert*, *Marshal P. Wilder*, *Heinrich Schulteis*, and *The Bride*. Dr. Budd, Bath, was second, among his being a very fine bloom of *Madame Lambard*, and good *Marie Baumann*, *Alfred Colomb*, *A. K. Williams*, and *Earl Dufferin*. Messrs. G. Cooling and Son, Bath, were third. The first prize for twelve varieties was also won by Messrs. Keynes, Williams & Co., among these being extra good blooms of *Beauty of Waltham*, *La France*, *Alfred Colomb*, *Mrs. Harry Turner*, and *Her Majesty*. Messrs. G. Cooling & Son were second, and Dr. Budd third, both having capital blooms. The best collection of twelve varieties of cut flowers was staged by Mr. W. Iggulden, who had Orchids, *Anthuriums*, *Ixoras*, *Dipladenias*, and other choice flowers well set up. Several others had good stands of cut flowers, notably Mr. Tucker, who had the second prize, and Mr. W. Strugnell, gardener to A. R. Baily, Esq., who made a slight mistake in setting up, and lost the second prize in consequence. The last-named was well first for a collection of hardy flowers, and also for vases of choice cut flowers and wild flowers, as well as a hand bouquet displaying excellent taste in each instance. The competition was good in all these classes.

Fruit was not largely shown. Mr. Pratt was first for a collection of six dishes, these including fine bunches of Black Hamburg and Muscat of Alexandria Grapes, Smooth Cayenne Pine Apple, Melon, Peaches, and Nectarines. Mr. W. Iggulden was second, and Mr. Phillips a creditable third. Mr. Pratt had fine bunches of Black Hamburg Grapes and was placed first, the second prize going to Mr. Iggulden, and the third to Mr. W. Strugnell, each having smaller but well finished bunches of the same variety. Mr. Pratt was also first in the class for white Grapes, having Muscat of Alexandria, large in bunch and berry but not well finished. Mr. Iggulden was again second. The last named was first in class for a Melon any variety, winning with *Blenheim Orange* in perfect condition. Mr. Pratt was second with *Longleaf Perfection*, a good green flesh variety not often excelled. Mr. Phillips was first for Peaches, winning with a good average dish of *Stirling Castle*, the second prize going to Mr. Pym for a good dish of *Barrington*. A grand dish of *Exquisite*, staged by Mr. S. Andrews, gardener to A. G. Hayman, Esq., was passed over on account of its being of doubtful quality, but this decision was far from meeting with general approval. Several good dishes of Tomatoes were staged, but Mr. Iggulden was well first with a handsome dish of *Hackwood Park Prolific*. Mr. Phillips was first for a brace of Cucumbers, and a capital lot of vegetables generally were staged. Messrs. Sutton & Sons offered prizes for a collection of six varieties of vegetables, and with these Mr. S. Andrews was well first, having *Tomato Reading Perfection*, *Potato Snowdrop*, *Cauliflower Sutton's King of the Cauliflowers*, *Cucumber Sutton's Improved Telegraph*, *Carrot Champion Horn*, and *Peas Telegraph*. In another class in which the prizes were provided by Messrs. Webb & Sons, Stourbridge, Mr. T. Evry, Bath, was first, having *Tomato Webbs' Sensation*; *Potato, New Discovery*; *Pea, Webb's Chancellor*; *Cauliflower, Erfurt Mammoth*; *Runner Beans, Webb's Giant White*; and *Cucumber Telegraph*. There were good numbers of exhibits in each class.

LEICESTER.

THE third annual Show in the Abbey Park was held on August 7th, which proved to be a glorious summer day, of which we have had very

few in the Midland counties this season. The Show would have been much more enjoyable without so much sun, the heat in the tents being at times almost unbearable. This was owing to a great deficiency of ventilation, and Roses and other cut flowers soon showed ill effects. The Show is held for the worthy purpose of assisting the funds for providing music in the park for the inhabitants of Leicester and other visitors during the summer months, and the people patronised it well, the number of visitors probably exceeding that of last summer, when over 20,000 people were admitted, so that a good balance will be available for the above purpose. Leicester people appear to be very proud of their park, and it certainly deserves to be appreciated to the fullest extent, being tastefully laid out and kept in excellent order by the curator, Mr. John Burn, who well deserved the praise accorded him by the Mayor when he opened the Show to the public. Mr. Burn gives much attention to all matters connected with the Show, which must give him a great deal of extra work, and it was not surprising that he was taken ill before the staging was completed, causing a considerable delay in opening the Show. It is not a good plan for one person to have so much to attend to, as a breakdown is liable to occur when the pressure is greatest, and the consequences may be serious. However, we were happy to find he had recovered sufficiently during the day to visit the Show. A falling off was noticed in some of the classes this season, but considering the small amounts of some of the prizes the competition in many instances was remarkably keen. This was especially noticeable in vegetables and Roses. Shows like this that are so largely attended possess a great power for good instruction of the minds of the public, and it would be well for the Committee to consider the advisability of extending this good influence by offering larger prizes in some of the classes for plants, in order to induce a few more exhibitors to attend from a distance. This would benefit the neighbourhood in many ways, not the least of which would be the improvement of horticultural knowledge, and also of the gardens and their owners, which would naturally follow.

The groups were arranged around the sides of a tent in half circles, Mr. Elworthy, gardener to W. Billson, Esq., taking the first prize. This group was well arranged, fresh and bright, and well finished to the margin. Mr. Murray, gardener to S. Bennett, Esq., was a good second, but had rather too many plants, and not enough colour in the outer part of his group. Third, W. Stephenson, Leicester; fourth, Messrs. J. & H. Hickling. The classes for six stove and greenhouse plants and for four foliage plants was very poorly filled. For six exotic Ferns, Mr. Barry, gardener to H. Snow, Esq., was first with even plants, closely followed by Mr. Elworthy, second, and Mr. Stephenson, gardener to J. Stafford, Esq., third. Amongst the other classes for plants some good Fuchsias and Coleuses were exhibited. Orchids were almost absent except in the group which occupied the centre of one tent, kindly sent by Mr. B. S. Williams, nurseryman, Holloway, London, not for competition. This comprised some good varieties of *Cattleya Gaskelliana*, *C. gigas*, *C. Schilleriana*, and *C. crispa*. *Odontoglossum vexillarium* very good in colour, *Oncidium violaceum*, *Anguloa Ruckeri*, *Masdevallia Harryana*, and finished off with Palms, Dracenas, Alocasias, Amaryllises, *Nepenthes*, &c., making a very interesting group.

Amongst the cut flowers, which were very numerous, especial mention must be made of several magnificent boxes of Carnations and Picotees sent by Mr. Turner of Slough, who easily took all the first prizes in the open classes; Messrs. Beal, Jackson, and Niemand securing the other prizes in these classes. The first prize variety in the class for single blooms was *Carnation Charles Turner* and *Picotee Favourite*. Hardy herbaceous flowers were a strong class, some of the stands containing Pinks, Carnations, *Chrysanthemums*, *Lupinus arboreus*, &c., requiring a good deal of elasticity in classification if they are to be considered herbaceous plants. Messrs. Pearson & Son, Chilwell, were first: Messrs. Biddles, Loughborough, second; Messrs. Harkness of Bedale third. A good bunch of yellow Sweet Sultan seemed to attract the ladies' attention more than anything else in this class. *Achillea millefolium* *roscia* in Messrs. Pearson's stand was also very conspicuous. Mr. Forbes, Buceleuch Nurseries, Hawick, kindly brought a quantity of very fine *Antirrhinums*, *Delphiniums*, *Violas*, and *Pansies* in great variety, not for competition, also *Phloxes*, which were crowded out. The long journey and the unbearable heat of the tents had told seriously on these, which would otherwise have proved a very interesting exhibition. Roses mustered strongly, and consequently some of the exhibitors showed a quantity of boxes of capital flowers without winning a place in the prize list. For thirty-six blooms Messrs. Harkness of Bedale were first with splendid blooms and very fresh, some of the best being *Ella Gordon*, *Etienne Levet*, *Horace Vernet*, *Her Majesty*, *Reynolds Hole*, *Duc de Rohan*, *Marie Baumann*, &c. Second, Messrs. Perkins and Sons, Coventry, larger flowers, but not so fresh. Third, Messrs. Mack and Sons, Catterick, fresher than the second prize bloom, but some rather small. In the class for twenty-four blooms Messrs. Perkins turned the tables on Messrs. Harkness, whose flowers were smaller, although very good on the whole; Messrs. Perkins' collection here being very good. Messrs. Mack again took the third prize. For twelve Teas or Noisettes Messrs. Harkness were first, Messrs. Paul second, Mr. Humphries, Chippenham, third. For twelve blooms of one variety, Messrs. Mack & Sons, Catterick, were first with a splendid box of A. K. Williams. Second, Messrs. Harkness with *Ulrich Brunner*. Third Messrs. Paul & Son with *Marshal P. Wilder*. Messrs. Pearson exhibited some splendid boxes of their celebrated Zonal Pelargoniums. Hand bouquet, first, Messrs. Perkins & Sons, Coventry, with a light and pretty arrangement. Second, Hans Niemand, Birmingham, whose

bouquet of yellow Roses and dark leaves was very much admired, and preferred by some to the first prize. Third, Messrs. Pearson. Bridal bouquet, first, Messrs. Perkins, with a splendid specimen. Second, Hans Niemand. Wreath of white flowers, first, Messrs. Perkins, with a very massive wreath, well finished in every way. Second, Messrs. Pearson, with a very pretty arrangement. For sprays Hans Niemand was deservedly first, his third being as near perfection as possible. Messrs. Perkins were second.

Fruit was well shown, Mr. Edmonds, gardener to the Duke of St. Albans, taking first prize for a collection of eight dishes with Black Hamburgh and Muscat of Alexandria Grapes (very good), a large Queen Pine, good Grosse Mignonne Peaches, Brown Turkey Figs, May Duke Cherries, and Best of All Melon, &c. Second, Mr. Goodaere, gardener to the Earl of Harrington, who had among other things a very large Pine, which, however, was not quite ripe, a fine Hero of Lœkinge Melon, and a plate of Cherries, named Le Château, which were worthy of especial notice. Third, Mr. J. Crawford, gardener to Colonel Thorpe. For two bunches of Black Hamburgh Grapes, Mr. J. Ward, Alfreton, was first; Mr. Edmonds second, but very little behind the first except in weight. White Grapes were not well coloured. Peaches, Nectarines, and Melons were well shown.

Vegetables formed a very large show in themselves, no less than thirty-six collections being exhibited in the four classes. Peas were strongly represented, and how the Judges arrived at a decision would be difficult to say; nineteen plates were shown, the majority being too old for good flavour. Broad Beans were very fine, and the spring Onions were large enough to have been sown in the autumn. In the cottagers' tent, Messrs. Harrison exhibited an interesting collection of Cabbages and Onions, the latter being grown at their seed farm in Italy, and were very fine bulbs. A great quantity of vegetables was shown by the cottagers, many of them being of good quality. The wild flowers and baskets of cut flowers were also very pretty, but as is usual in this tent very closely packed together by those who tied them up. It is to be hoped some of them took a lesson from the open classes before leaving the Show. In order to develop taste and knowledge among the cottagers it would be well to stage their exhibits nearer to the open classes of the same character.—J.

HURSTPIERPOINT.

THIS Society held its second annual show at the Chinese Gardens on the 8th inst., and considering the extraordinary season we have had, and its coming so soon after the "wettest July on record," they may well be satisfied with the result of their labours. Over 100 exhibitors entered, and the number of exhibits was considerably greater than last year. Like all local shows the great object is to promote cottage gardening, and a list of the prizewinners would not be of interest to the widely scattered readers of the Journal. These societies, however, do so much good that I sometimes think they should have a little more notice taken of them by the Horticultural Press than is generally the case. "A Wanderer" has been giving his experience amongst "Black Pigs and White Elephants." No doubt those who judged the cottage gardens for the above Society could relate similar experiences, for the inhabitants of snug little towns at the base of the Downs evidently believe in both. When coming out of the show tent I ran up against an enthusiast carrying a tray, on which was arranged a little family of Elephants to the number of seventy—the produce of one tuber planted whole. The show of vegetables was very good in all classes, with the exception of Runner Beans, and Cauliflowers were not a very good sample. Messrs. Sutton's prize for a tray of vegetables was won by Mr. F. Godby of Burgess Hill, the same gentleman taking first for black Grapes with compact, well coloured bunches, and also first with well-grown plants of Fuchsias. For a group of plants first place was given to G. F. Wickham, gardener to J. Humphry, Esq., Keymer. Most taste in arrangement was displayed in the second prize group with very ordinary material, while the best lot of plants was placed third, the arrangement being extremely stiff. A. Bisk was first for six specimen plants for small, healthy, well-grown plants, and also for six Gloxinias with splendid plants.

There was a good contest for Messrs. Balchin's prize for hardy herbaceous flowers, W. Manton being the fortunate winner. A very interesting feature was the class for a basket of cut flowers for ladies only. There were nine entries, and when the ladies were present there was little chance of one of the sterner sex getting a peep at them. Light graceful arrangement distinguished the two winning baskets of Miss Hannington and Miss K. Broad. Messrs. Balchin of Hassocks Nursery sent a neat group of plants not for competition, as did also G. B. Woodroff, Esq., the latter gentleman showing splendid bunches of Muscat and Black Hamburgh Grapes, also not for competition.

The Committee of this young Society are fortunate in four respects:—First, in having the substantial support of so many of their local townsmen in giving special prizes. Legs of mutton, pairs of boots, &c., as well as money prizes, are worth trying for in these hard times, and is an example that might well be followed by some of their neighbouring towns where there are similar societies but scantily supported in that respect. Secondly, in Mr. Niel they have an excellent Hon. Secretary. Third, in securing the services of two such experienced superintendents as Messrs. Richardson and Bunney; and last but not least, in Mr. W. Wood they have an admirable Chairman and Treasurer. The weather on this occasion was simply splendid, and has continued so since.

HARDY FRUIT GARDEN.

RIPE FRUIT AND ITS PROTECTION.—Fruit generally has coloured, or is colouring well, and is of good size, but in most instances it is unusually sour. Red Currants are perfecting a remarkably heavy crop of fruit, and as this will hang for a long time after it is ripe extra care should be taken of all that is not wanted for immediate use. Where the clusters are very thick they ought to be freely thinned, otherwise the fruit is liable to decay in a wholesale manner. Birds must also be excluded from them, either with the aid of fish-nets or mats, and thus protected the fruit will sometimes keep good till late in October. Black Currants do not long hang on the bushes, and these also ought therefore to be gathered, some being made into jam, and many more bottled off whole, corked up tightly, and then immersed in water in a pan or copper, care being taken to divide the bottles so as to prevent their banging against each other. Set on a steady fire; gradually heat to boiling point. Keep the water steadily boiling for about half an hour, and allow it to cool before taking out the fruit. Thus treated Red and Black Currants, Gooseberries, Raspberries, and Cherries will keep a long time, and when made into pies are equal in flavour to quite fresh fruit. Gooseberries, as a rule, do not hang on the bushes any great length of time after they are ripe, the most noteworthy exception being the Red Warrington. The bushes of this variety ought always to be grown in a plot together, where they can be protected by either fish-nets or galvanised wire netting, supported by a framework of some kind. The larger smoother varieties crack badly in showery weather, and these ought therefore to be protected from rains as much as possible. Mats will keep out a moderate amount of moisture, but are not nearly so effective as spare frame lights fixed over any extra good crops of fine fruit.

WALL FRUIT.—Cherries have cracked badly, more especially those that ripen in July. Florence, a good type of Bigarreau, though much later, is yet sound and good, and in all probability will keep till late in August. It is one of the best for wall culture, and will be available when all other choice varieties, including the good-keeping Governor Wood, are over. Morellos are very late, and where they have set thickly and not been thinned, will be small. They hang for several weeks on the trees, and should be closely netted, or the birds will soon clear them off. Plums are swelling rapidly, and promise to be larger than usual. In many instances they have set so thickly that unless freely thinned out none of the fruit will be of good quality. It is rather late to commence thinning, but it had better be done now than not at all, especially in the case of Guthrie's Late Green Gage, Kirk's Washington, Jefferson, Reine Claude de Bavay, Coe's Golden Drop, Blue Impératrice, Ickworth Impératrice, and any other late-ripening variety. The three last-named will hang the longest on the trees, and ought therefore to be the last to be used. None of the Gages keep very well, and these, Jefferson, Oullins Golden, and other choice but bad-keeping varieties should be largely gathered, and made into preserve when nearly ripe. Apriots are fast changing colour, and these again keep badly. Some of the most valuable preserve is made from this fruit, and it need not be very ripe for the purpose. Slugs are very troublesome among Apriots and stone fruit generally, eating or disfiguring many just when changing colour. They ought either to be looked after at night with a lamp and destroyed, or else trapped with the aid of slates or heaps of Cauliflower leaves laid at the foot of the walls. Little heaps of brewers' grains also are a great attraction to slugs, and will save the wall fruit. In dry weather, if the borders near the wall are heavily dressed with soot and lime occasionally this will greatly check the slugs. Snails are frequently troublesome, but as these usually remain on the walls or under the foliage of the trees they must be hunted out and crushed.

SUMMER-PRUNING OF PEAR TREES.—Many experienced fruit growers are of opinion that July is too soon to resort to summer pruning, at any rate as far as the use of the knife is concerned. If the stopping is not done early with the finger and thumb the pruning is delayed till the early part of August. Pruned much earlier the effect is merely to induce the formation of many more sappy branches, whereas when delayed till now there is much less likelihood of this occurring, and the trees are encouraged to concentrate their vigour towards swelling off the fruit, and the formation of numerous well-placed fruit and wood buds. As far as large pyramid and bush-trained trees are concerned, these being less liable to smother the fruit with growth, little or no pruning need be done till the foliage has fallen, but the wall trees ought to be attended to. All the young growths not required for furnishing on unoccupied space ought to be pruned to a length of from 5 to 6 inches, or cut just beyond the sixth or seventh joint. When cut much harder there is a risk of converting those at the back joints into wood rather than fruit buds, and it may be force many of them to start into growth prematurely. The final pruning should then be delayed early in the winter. Leading shoots, including those to form more main branches, must be carefully fastened to the walls, and kept as straight as possible. If this training is delayed till the wood becomes

firm it cannot subsequently be done without the risk of snapping them in two. Owing to the lateness and softness of the central growth of espalier or horizontally trained trees it is not advisable to shorten these back with the motive of securing a second pair of branches in one season. No doubt these would form readily enough, but it is very doubtful if such late growth would ripen properly this season, and unripe wood is not suitable for laying the foundation of a profitable tree. Summer Doyenné or Doyenné d'Été will soon be ripe, and though small is very good in quality if gathered and eaten at once. Citron des Carmes is a little larger and somewhat later, and this also must be eaten direct from the trees, as when kept it soon becomes dry and mealy.

FRUIT FORCING.

PEACHES AND NECTARINES.—Early Forced Trees.—Trees that have been subjected to early forcing for a number of years acquire a tendency to premature development; notable in this respect are Early York and other varieties, particularly those having large flowers. This can only be prevented or lessened by allowing a moderate extension of the laterals, exposing the trees to the air by the removal of the roof lights, or it may be arrested by the maintenance of a dry atmosphere and a somewhat dry condition at the roots, but this tends to cause premature ripening of the foliage, and subsequent wholesale loss of the buds, being worse than the loss of a few buds from premature growth. With the trees fully exposed the foliage will ripen freely, and where the roof lights are not moveable admit air to the fullest extent, maintaining a good moisture in the borders, damping the house occasionally in hot weather. Some of the foliage of the trees in the earliest house, or that started in November or early December, will now or shortly begin to fall; but do not accelerate this by brushing the trees, only remove such as are ripened for the purpose of destroying insects. Trees showing indications of weakness should have the roots bared and the soil removed, supplying some rich rather strong calcareous soil, adding marl if the soil be inclined to be light, or old mortar rubbish if it is heavy, working it well amongst the roots, and making it quite firm, following with a good watering. Damping the trees occasionally will facilitate speedy root action, and in case of lifting the roots, as may be necessary if they are deep, and laying them in fresh soil nearer the surface, shade from bright sun will be necessary, with a rather close and moist condition of the house.

Preparing for Planting.—It is too early as yet to plant fruit trees, yet all trees for Peach houses should be removed thereto before the leaves have fallen; indeed, as soon as the wood is in a condition to admit of it without danger of shrivelling. It is not, however, too early to select the trees for planting, having them marked at the nurseries for removal when in a suitable condition. Select those that have the branches evenly balanced, and have short-jointed, vigorous, but not over-luxuriant wood. Some of the best and most reliable for early forcing are Hales' Early, A Bee, and Royal George, or its hardier form, Stirling Castle. The best companion Nectarine is Lord Napier. If fruit is required very early, then such varieties as Alexander, Waterloo, Early Beatrice, Early Louise, and Early Rivers may be planted; the quality of those is not equal to the others, though the last three are superior in that respect to the first two—i.e., Alexander and Waterloo, the chief recommendations of which are their extreme earliness and good appearance. For succession houses, Peaches Grosse Mignonne, Noblesse, Bellegarde, Belle Baucé, Goshawk, and Barrington. Nectarines Elrue, Violette Hâtive, Rivers' Orange, and Pine Apple. Late houses, Peaches Walburton Admirable, Princess of Wales, Sea Eagle. Nectarine, Victoria. It is usual to include some of the midseason varieties in the late houses, hence the few varieties named, such as Dymond and Barrington being indispensable, as also is Pine Apple in Nectarines. For wall cases a succession of fruits can be had from the middle of July by planting Alexander, Hales' Early, Stirling Castle, Alexandra Noblesse, Bellegarde, Belle Baucé, Barrington, Walburton Admirable, and Sea Eagle. Nectarines:—Advance, Lord Napier, Elrue, Rivers' Orange, Pine Apple, and Victoria.

The borders in which trees are planted for early forcing should be inside, wholly or at least partly, whilst those for later succession should have the run of outside as well as inside borders. The borders should be well drained, using 4-inch drain pipes, and having proper fall and outlet. Provide a foot depth of drainage, brickbats, sand, or freestone, or preferably chalk answer, placing the roughest at the bottom and finest at the top, the latter not being larger than broken road metal. If the drainage could be secured by a layer of old mortar rubbish 2 or 3 inches, which has been freed of the finer particles by passing through a half-inch sieve, it will be a means of preventing the roots passing so freely into and rioting in the drainage, besides affording calcareous and siliceous material and facilitating lifting operations. Good strong loam of the calcareous formations is best, the top 3 or 4 inches with its turf of an old pasture. If very light add a fourth of clay marl in as fine parts as practicable, and if very heavy a similar proportion of old mortar rubbish, but for ordinary light soil a sixth of clay marl, and for rather stiff loam a sixth of old mortar rubbish will be a fair admixture. A few crushed steamed bones, about a bushel to a cartload, or one part in thirty, will be all that is necessary to grow the finest fruit, but if the loam be not turfy add a fifth of stable manure, the strawy portions being shaken out with a fork, or for light soil cow manure may be used. The border should be 24 to 27 inches deep, and a width of 4 to 6 feet will be sufficient to commence with, and in no case need exceed the width the trees cover of trellis. The material must be used rather roughly, well incorporated, and put together when dry, so as to admit of its being well firmed. Allowance must be made for settling.

Succession Houses.—As soon as the fruit is gathered from the trees cut away the shoots that have borne fruit, unless they are extensions, and thin all the growths where too crowded. Admit air to the fullest extent, and syringe occasionally to free the foliage of red spider if any appear, applying an insecticide if necessary. The inside borders must not be allowed to lack moisture, giving a good watering if necessary, and the trees being weak and not plumping the buds well afford liquid manure.

Late Houses.—Trees in these will need frequent attention in thinning and regulating the summer growths, and if they are laid in thinner than usual it will in a measure compensate for the deficiency of sun. Gross growths, of which there are plenty this season, must be stopped or removed. Endeavour to secure a balance of moderately strong wood, and to insure the ripening as well as to improve the flavour of the fruit gentle fire heat, especially in low and in cold situations, will be of great benefit. Give attention to syringing until the fruit commences ripening, so as to keep the foliage free of red spider, and water the inside border as may be necessary.

Unheated Houses.—The hope is that the present sunny weather will last, of which every advantage should be taken, ventilating early and moderately through the day, so as to make up for lost, closing early with a view to insure a long day's work, but admit a little air at night to allow the temperature to gradually cool and the pent up moisture to escape. Keep the growths thin, and the foliage clean by judicious syringing.

FLOWER GARDEN.

Auriculas and Anemones.—Quite new seed invariably germinates more readily and the seedlings are stronger than any that result from sowing old seed, consequently care should be taken of all seed pods on both the Alpine Auriculas and Anemones. As soon as the seed is well ripened sow it on the surface of a pan filled with fine sandy soil and cover lightly. Set the pans in a handlight or cold frame and shade from bright sunshine. The Anemones germinate evenly, the Auriculas more irregularly, some of the seedlings appearing in a month or less and others much later on, and the soil ought not, therefore, to be much disturbed when the earliest seedlings are pricked out in other pans of fine loamy soil. The Anemones need not be interfered with unless very thick, and if planted out early in the spring will give a few flowers the same season.

Violets in Hot Weather.—The greatest enemy Violets have is the red spider, this in some instances completely crippling the plants. Nor does a long spell of showery weather much check the ravages of this little pest. The best remedy is to frequently syringe the plants with water to which sulphur has been freely added. A good handful to a 3-gallon can of water is sufficient, and it can be most readily mixed by being worked through a bag made of muslin or fine netting. If the leaves both on the under and upper sides are well coated with sulphur this will effectually check the red spider and a healthier growth result. Sickly foliage will not build up good crowns, and in addition is very easily killed by frost. Light land may be made more cool or better adapted to the growth of Violets by receiving occasional very light surfacings of common salt, care being taken not to let any of this fall on the leaves.

Weedy Walks.—Weeds are very abundant everywhere, and on gravel walks especially are not easily destroyed by ordinary means. A good surfacing of salt will kill a good many of them, but is not nearly so effective as Smith's weed killer. This, by no means an expensive remedy, only requires a liberal addition of cold water before its application, and never fails to destroy all weeds it comes into contact with. Full directions are sent with this poisonous compound, which should be strictly adhered to. It only remains to be added that those using it must not walk over turf or splash it in any way, or brown patches will be the result. The turf or Box edgings ought to be protected with the aid of boards slid along as the moisture is being applied. All that is necessary is to thoroughly wet the weeds and they soon disappear. In some positions every second year is often enough to use this remedy.

PLANT HOUSES.

Begonias.—If the varieties intended for autumn and winter flowering have not been placed in their largest pots it should be done at once. Insert cuttings of Begonia nitida, B. nitida rosea, B. Ingrami, and others that are useful for flowering from February to April. Cuttings of these should be placed singly in small pots to accommodate them until the close of the year, when they can be placed in 4 and 5-inch pots.

Panicum variegatum.—Prepare a number of 3 and 4-inch pots of Panicum for decorative purposes during the winter. Insert the cuttings thickly together, and if they are kept close and shaded from the sun they will soon become established. To have these in good condition they must be grown for some time after they are rooted; in fact, until the pots are filled, and then they are highly ornamental. Pittonias may be rooted in quantity for the same purpose, only these should be inserted singly, or if rooted together they may be placed into 2-inch pots afterwards. A good plan is to root them in pans and then establish them singly in bunches of moss. These, if placed thickly together in boxes with soil amongst them, are easily kept moist, and have good balls of roots when lifted for association with Selaginellas and small Ferns. This method is as good as potting them singly, for if required in pots they can be placed in them as required.

Bertolonias.—In order to keep these in good condition through the winter root cuttings at once. Plenty can generally be taken from the base without injury to the plants. Young plants raised from cuttings are easily preserved in an ordinary stove through the winter, while large

fully grown plants are very liable to die. Cuttings root freely in any light sandy soil if they are kept close in the propagating frame or under handglasses, provided they are shaded from the sun.

Sonerilas.—However good pots or pans may be at the approach of winter they are very liable to damp off before spring. The only means of keeping them safely through the winter is to strike cuttings at the present time. The best plan is to insert a number of cuttings in 3 to 4-inch pots, in which they should be allowed to grow until spring, when they will yield cuttings in abundance for making pots and pans for the ornamentation of the stove during summer.

Epiphyllums.—Plants that have completed their growth should be gradually hardened and fully exposed to the sun to ripen them, for upon this depends whether they flower profusely or the reverse. Water carefully, but do not allow the plants to suffer by an insufficient supply. Encourage in a genial temperature those that have not yet completed their growth. Plants worked in spring are still growing rapidly, and these must have a fair amount of light or they will prove too soft to flower freely.

Amaryllises.—When growth is completed *Amaryllises* must still be liberally supplied with water, at the same time give abundance of air and expose them to full sunshine. Make no attempt to dry them by withholding water. As the bulbs complete and mature their growth the foliage will naturally fade. Assist seedlings to grow as luxuriantly as possible, but be careful not to keep them too close or overshadow them so as to draw up their foliage weakly. If the young plants have abundance of roots weak stimulants will be beneficial.

Thysacanthus rutilans.—Plants that are well established in 5 and 6-inch pots should be grown under cool frame treatment. If kept in the stove they soon become a prey to scale and run up very tall, which is not the case when cooler treatment is given. When they have rooted freely in their largest pots give weak soot water in a clear state about twice a week, which will impart a fine dark hue to the foliage. With good treatment this plant should have at flowering time dark green foliage down to the rim of the pots. Plants in this condition are very effective when in flower elevated above others to display their slender drooping stems of scarlet flowers.

Winter-flowering Plants.—The weather has been so cold that many stove and intermediate plants could not be shifted into cool frames. Up to the present time it has been necessary to use fire heat generally for these plants, and the pits and houses they occupy are becoming too crowded. The weather appears to have changed, and these plants must be thinned so as to give them room to develop. If care has been taken to use no more fire heat than has been absolutely necessary *Poinsettias*, *Euphorbias* and such plants will be in good condition for removal to cold frames without fear of checking them.

THE BEE-KEEPER.

PROSPECTS OF THE HEATHER HARVEST. THE PRICE OF HONEY.

THE desolate appearance of the moorlands hardly augurs well for the Heather harvest. Walking from Buxton over the moors in the direction of the "Cat and Fiddle," and striking out thence in various directions on a day having more of November than July in it, we were struck by the appearance of the Heather, which can hardly fail this year to be unusually late. The weather—cold, wet, and sunless—lends no help, and with a continuance of the same conditions for another fortnight bee-keepers will be wise to look carefully into the prospective profit before exposing their stocks to a winter's weathering on the hillsides with only a small chance of a profitable result. The Heather harvest is at the best very fatal to the bees, sudden storms sweeping them away to destruction and almost depopulating the hives; and yet, provided the Heather is in good bloom and the weather is at all promising, the future result is worth the present risk, especially in those localities where, as "A Lanarkshire Bee-keeper" informs us, driven bees may be had in almost any quantity at a merely nominal price. With the certainty of thus being able to reinforce our stock by adding bees obtained in such a manner the winter may be looked forward to without anxiety, but where the bee-keeper has to purchase his bees at a high price, and can then with difficulty obtain them, the winter will be disastrous to stocks sent to the Heather unless the conditions are favourable. If, however, the weather during this month and next should be favourable, those bee-keepers

who are able to obtain a harvest of Heather honey will reap a profit larger in proportion than in other years, where the Clover and low-land bloom has yielded a large surplus of good quality, and the price of Heather honey has in sympathy with an overburdened market fallen to a lower price than that which is usually obtainable for the cream of nectar.

It may not be out of place to remind those bee-keepers who have honey in hand that they can to a very great extent control the price this year, and that the value of good honey is certain to rise very perceptibly unless some bee-keeper's friend—possessing the power to do so—imports foreign produce, and by doing so floods the market and keeps the price at a figure which, though it may be profitable to the wholesale dealer and the middleman, hardly pays the bee-keeper a just wage for his labour and a due percentage on his capital. We hope that patriotism may withstand the interests of the pocket, and that no importation of foreign produce will be brought about by those whose duty it is to foster the British industry.

Already the retailer is inquiring for honey. Last year the producer had to search for the purchaser. The purchaser in the past has been to a great extent the master of the situation. The bad season has changed all this, and the man who looks after his own interests will obtain a large price for his product; but in order to do so he must be in no hurry to dispose of his surplus, but quietly await the turn of events, taking not necessarily the first opportunity of getting rid of his stock, but the rather waiting and availing himself of the first offer which will enable him to clear out at a price which shall be relatively higher in proportion, as the surplus this year has been less than in the last few preceding seasons. One-pound sections should realise at least 15d. each, and some have been disposed of already at an even higher price. Those who have kept over a stock from last year will have their reward now, while those who assisted in the autumn to flood the market, and to lower prices by doing so, will now, no doubt, regret that they sold at a sacrifice what could now be sold at a really remunerative price. At the present time we have some sections taken last summer which are in the finest condition, and which will, no doubt, realise a very high price, as we have already had more than one good offer, although the price offered has not yet tempted us to sell. Comb honey, if kept in a warm dry cupboard well covered up and preserved from mice and insects, will keep a very long time in good condition, and in many cases no perceptible granulation will be perceived, but certain kinds of honey do undoubtedly granulate almost immediately after removal from the hive. Such honey is comparatively valueless for sale in the comb, but as bee-keepers know, honey extracted from the comb may, if it granulates, be reduced to a liquid form again by judicious heating, but care must be taken not to expose it to a greater heat than necessary, because the stronger the heat the greater the loss of aroma and flavour. Granulated honey in the comb is of relatively small value; granulated run honey may be reduced to its first state with little loss. It is for the bee-keeper to say whether the difference in price between comb and extracted honey will compensate him for the extra risk entailed in the case of comb honey, and having formed his conclusions, the individual bee-keeper must act upon them, and the result will, in the end, depend upon the wisdom of his conclusions.

In future issues it is our intention to treat of the preparation of stocks for winter, with the object of impressing upon all bee-keepers the necessity of exercising present care if they desire future success.—FELIX.

TRADE CATALOGUES RECEIVED.

Dicksons & Co., 1, Waterloo Place, Edinburgh.—*Catalogue of Flower Roots, 1888.*

William Cutbush & Sons, Highgate.—*Catalogue of Hyacinths, Tulips, &c., 1888.*

Sutton & Sons, Reading.—*Illustrated Catalogue of Bulbs.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (T. W.).—Our answer to your question is in the negative. We have no such work on sale.

Chrysanthemum Leaves Eaten (W. J. M.).—The leaves appear to have been eaten by the small caterpillar that sometimes attacks the plants, and which is the reverse of conspicuous. If you examine with care the under sides of the leaves you will possibly be able to detect the culprits and secure them.

Golden Elder (R. A. E.).—The leaves you enclose are well coloured examples of this easily grown and effective hardy shrub. It can be had from all nurserymen who grow trees for sale. The summer shoots are best cut closely back each autumn, as not only are the shrubs then kept dwarf, but their colour is brighter than when pruning is not resorted to.

Dressing Vine Border (J. S.).—If you have applied such heavy dressings of manure for many years consecutively you cannot probably do better than cover the border with lime to the depth of half an inch, and point it in lightly with a fork, not disturbing the roots of the Vines. A light dusting of soot in spring, just making the border black, would not burn the roots, but is not the border rich enough without it!

Chrysanthemum Leaves Eaten (T. S.).—The shoot you have sent has been punctured just below the terminal bud by a small weevil, but whether the pupa you send is one of the forms of the same insect we cannot determine, as it is in a transition state that is not peculiar to itself. We suspect also, indeed are practically certain, that the leaves have been eaten by earwigs or a small caterpillar. The plants should be carefully examined at night with the aid of a lamp.

Gloriosa superba (T. Bickley).—This is the correct name of the plant you have as *Gloriosum superbum*. It is of climbing habit, with orange coloured flowers, and well worth cultivating in a stove or warm conservatory. It belongs to the Lily family. The genus *Antigonon*, of which the other plant is probably a species, is related to the *Polygoniums*, the plants being ornamental climbers, which some have compared to *Bougainvilleas* in attractiveness. They also require stove treatment.

Planting Lilliums (J. T. B.).—If we had a number of plants of *Lilium auratum* just ceasing flowering, and desired to establish them in a border, and also, like yourself, "wanting the pots," we should not hesitate to turn the plants out at once into the border. We should make the soil good to a depth of from 18 inches to 2 feet, then plant the Lilliums without materially disturbing the roots, 2 or 3 inches deeper than they are in the pots. Cut off any seed pods that may have formed, and secure the stems to stakes, leaving the growths to ripen naturally. It is a mistake to withhold water immediately after flowering ceases, and thus drying off the plants prematurely.

Grapes Scalded (Andromeda).—We have received the Grapes but not the letter of particulars which you notify having sent. See reply to "A. B. C." last week. Your Grapes also show symptoms of mildew. The moment you see any on the foliage and berries dust them with sulphur. The long term of dull weather has made both the foliage and fruit of Vines tender, and unable to resist the sudden outburst of sun, except under the most judicious method of ventilation, and in some cases light shade, such as sprinkling the glass with white-wash or covering it with netting, has been necessary to prevent injury. You should have sent sooner. Short answers are compulsory to Wednesday morning's letters, the alternative being the delay of a week in the publication of replies.

Herbaceous Plants (T. W.).—The term "herbaceous" has caused many disputes at flower shows, and though it is often employed in schedules without a very definite idea of its true signification, judges cannot be on safe ground if they do not construe the term literally in the absence of any qualification or special rules. The word is simply defined in one of the most recent botanical dictionaries as meaning "an annual stem springing from a perennial root," and in the majority of cases there is little difficulty in deciding whether a plant possesses this character or not. Strictly speaking, annuals and biennials would not

be admissible, and all perennials that do not lose their stems every year would have to be excluded; on the other hand, the flowers of nearly all hardy bulbs could be shown in such a class. The conditions of a class ought certainly to be complied with, but too much care cannot be exercised in framing schedules to make the matter clear. The term "hardy" is really more indefinite than "herbaceous," for scores of plants might be hardy near the metropolis that could not be so described in your district, and in judging these classes the locality must be considered as well as the plants shown.

Brugmansias (S. Oates).—The "tree-like plants bearing large white trumpet-shaped flowers in Battersea Park" are *Brugmansias*. They are wintered in greenhouses. If you procure some keep them rather dry in winter, or so dry as not to allow the wood to shrivel, and prune in spring (March) to a few eyes of the old wood. Water carefully or moderately until the young shoots are an inch long, then repot, disrooting (at least remove most of the old soil), and return to the same size of pot. Water carefully, just keeping the soil moist, and syringe lightly overhead with water morning and evening. Slight shade is advantageous until the potting is recovered. The pot full of roots shift into one-fourth larger in diameter, watering moderately for a time until the roots are in the fresh soil, then copiously, and syringe twice daily, directing the water against the under side of the leaves, and the pot full of roots; employ weak liquid manure. A light, airy position, and abundant waterings without making the soil sodden. Three parts light fibrous loam, half part each leaf soil and old dry cowdung, with efficient drainage. Cuttings of stubby shoots half ripe in sandy soil, in gentle heat under a handglass, shaded.

Disputed Cup (J. W. M. E.).—The case is so unusual and peculiar that we publish your statement, in case any of our readers learned in the law may be able and willing to give their opinion:—"Copy of Schedule, Bawtry Flower Show, 1885.—A handsome silver eup will be given by Viscountess Galway for best arranged vase of flowers by any lady. The eup becomes the property of the successful exhibitor until the following Show (August, 1886) when it must be returned to the Committee, and if again successful it becomes the *bona fide* property of the winner. Mrs. Egglestone the gardener's wife of Firbeck Hall, won the plated claret jug it turned out to be. There was no Show in 1886 nor in 1887. A fresh committee was formed this summer, calling itself the Bawtry Horticultural Society, and have demanded the jug. Mrs. Egglestone does not care to compete again, and is not willing to give up the jug for nothing. If you will kindly give your opinion in next week's 'Journal' you will greatly oblige." Our opinion is that the case is one for a solicitor, but if the new organisation is entirely distinct from the old, the former being dead, we suspect the present Committee will not find it easy to establish a claim for the cup; but if the Committee is a continuation of the former one, there having been no dissolution of the old Society, we should think the holder of the eup less secure in its possession.

Stocks for Roses (Puzzled).—You will perhaps remain puzzled till you settle the matter for yourself, for we suspect no stock can be pronounced the best for all Roses and all soils. The Rev. J. H. Pemberton, a very successful Rose grower, has given the following as his opinion on stocks in the "Rosarians' Year Book":—I. Manetti.—A strong growing stock, does well on all soils, makes good roots, but likes to assert itself. It suits some H.P.'s, but not those of the smooth-wooded Comtesse d'Oxford type, and Teas have a great dislike to it. It is easy to bud, takes readily, and makes strong plants. The maiden blooms have a tendency to coarseness, and require great care in disbudding. As cut-backs, I do not like them. This indeed is their weakest point, for they lose heart when pruned either hard or long, and break very feebly. The Manetti seems well suited to secure new Roses, for it takes well, and produces much wood for securing buds next year. II. Seedling Briar.—A good stock for all Roses, does well on clay soils, and has no equal for permanent cut-back plants. It produces maiden blooms almost too late in the season for exhibition, although as cut-backs it is quite as early as any other stock. It does not bud well, the stocks not being always straight or regular in size, so that more care is required to suit the bud to the stock than in the case of the Manetti or Briar cutting. III. Briar cutting.—Suits all Roses, does well on clay soils, has no equal for producing good exhibition blooms on maiden plants, and, moreover, early blooms. It is not so good as the seedling Briar for permanent plants, but in all other respects it is by far the best stock, being regular in growth and buds well. My opinion then is this: for permanent plants, grow seedling Briar. For maiden blooms, grow Briar cuttings. For plants to bud from, grow Manetti. If, however, I am requested to decide upon one stock in particular, I should give the preference to the Briar cutting.

Potting and Managing Camellias (G. Welton).—Large shifts are not good. An inch larger all around than the ball ought to be the maximum, and half an inch the minimum, and with the former allowance of root room the plants need not be potted oftener than every other year or third year if the plants grow freely, and every year when the smaller shift only is given. Potting is perhaps best done at the close of March, just when the flowering is past, and at the close of August. Both times are good. They should have a compost of three parts light very fibrous loam, the top inch of a pasture taken off with its turf, and chopped up, roughly, and one part sandy peat, with a free admixture of sharp sand. The roots being very brittle the potting should be done with great care, not injuring the roots, but picking away the old soil not occupied with live roots, and freeing the surface of moss. Drain the pots efficiently—about one-fifth the depth of the pots—and

put over the drainage an inch or so of the rougher parts of the compost. Pot so that the setting on of the roots will be elevated in the centre of the pots rather higher than the rim of the pots, and pot firmly, working the soil in around the ball with a stick. The soil should be moderately dry when used; if wet, the operation cannot be properly performed. Finish off with the finer portions of the soil, and water for a few times with a rose watering pot. In case of unhealthy plants, turn them out of the pots in spring, remove all the old soil and decayed roots, but preserving any fibrous parts, and repot in the compost above named firmly, working it well in about the roots. The plants should never want for water at any season, and during their growing period very copious supplies should be given, or from March to July. After March they ought to have shade from bright sun up to September, a thin canvas or tiffany shading answering well. After June the soil should be kept moist, not watering, however, until it shows indications of dryness, then give thorough supplies, enough to moisten the ball through, and this they need all through the winter. When the buds are swelling they may be watered with weak liquid manure at every alternate watering, commencing in November if expected or likely to be in bloom about Christmas, and continuing until the flowering is over. Guano, 2 ozs. to a gallon of water is a good application, or 1 peck fresh dung of horses, sheep, or cows, and 1 peck soot to 60 gallons of water, stirring well up before use. This not only assists the swelling of the buds, but acts as a stimulus to growth, plants so treated making a vigorous growth after flowering.

Propagating Show and Fancy Pelargoniums (Youngster).—Cuttings may be put in and struck from March to August; the general time, however, is when the plants have done flowering, and require cutting down to make bushy plants for the next season. This generally happens from the end of June to the beginning of August. They may be successfully propagated in a frame set upon a spent hothed, first removing the soil and replacing it upon a thick coat of coal ashes to keep out the worms. Upon this place a layer of sawdust to plunge the cutting pots in. The best soil is pure loam mixed with silver sand. Five inches wide at the top is a proper size for the pots, which must be well drained. Fill them to the top with the prepared loam, which should be put through a rather coarse sieve to take out the stones. It should not be pressed down too hard, but made firm enough to hold the cuttings fast. Use it in a state neither wet nor dry. The side shoots which have not flowered, and are not more than 2 inches long, make the best cuttings. These should be cut off close to the stem. If taken off with a sharp knife they will not require to be cut again at the bottom, unless the cutting is too long; then they should have a clean horizontal cut just under a joint to make the cutting the right length. Cut off the bottom leaves close to the stem, leaving only two of the uppermost. Place the cuttings in a shady place to dry up the wound. This will take an hour on a dry day, or two hours on a dull, cloudy one. Then put them in the prepared pots round the edge, inclining the leaves inwards, so that they may not touch the leaves of those in the contiguous pots in the frames or in the propagating house. When a pot is filled give a gentle watering, and set it on one side to evaporate the moisture on the leaves and surface of the soil. Then plunge the cuttings in the frame, and shade them from the sun till they form a callosity (a swelling at their base). After that, reduce the shade gradually, using it only during bright sunshine. A little air may also be given every day by tilting the lights behind. The cuttings must be frequently examined to see if roots are formed; and as soon as they are an inch long place them into 60-size pots. A small addition of well-decomposed leaf mould may be mixed amongst the loam with advantage. When potted give another gentle watering, and replace them in the frame; renew the shading, but disuse it as soon as it is safe to do so, and then give plenty of air to prevent their being drawn up and spindly. To cause them to become bushy plants nip off the top bud; the lower side buds will then break, and the shoots from them must be again stopped as soon as they have made three leaves. The plants will then be ready for a second potting, and should be removed into the open air. The above directions, as far as the cuttings are concerned, relate only to the show varieties, as they are called; but fancy varieties are more difficult to increase by cuttings. Insert the cuttings of these in shallow pans, 1½ inch deep, with a hole in the centre, in the usual loam and sand, placing them on a shelf in the propagating house, or in the frame close to the glass upon inverted pots. Make the cuttings very short, with a portion of the old wood at the bottom of each. Very little water is to be given till the callosities are formed; afterwards give it more freely, and when roots appear immediately pot the young plants and give the usual treatment.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*J. C. C.*).—1, *Diplacus glutinosus*; 2, *Begonia metallica*; 3, *Fuchsia procumbens*. (*J. S. U.*).—1 and 4 were not sufficiently fresh for recognition; 2, *Scrophularia aquatica*; 3, *Euphorbia helioscopia*. (*H. J. E.*).—*Lilium lancifolium rubrum*, a good variety, highly worthy of culture. We are obliged, by your encouraging letter. (*A. C.*).—The specks on the leaves appear to be of a fungoid nature, the result possibly of the wet season. The *Spiraea* is *S. callosa*. (*A. W.*).—One of the conditions upon which we undertake to name plants is that the specimens be accompanied by flowers. We can only suggest that 1, 2, 3, and 4 are

Odontoglossums, 5 is probably *Epidendrum vitellinum*, and 6 resembles a *Cymbidium*. (*W. Berks*).—The Orchid, we think, is *Epidendrum variegatum*. The *Miltoufia* is not specially subject to the spotting of which you complain; perhaps it has been too freely watered over the foliage. (*H. E. M.*).—The leaf is like a small example of *Clianthus puniceus*; the Californian flower was too much damaged to be recognised.

COVENT GARDEN MARKET.—AUGUST 15TH.

BUSINESS quieter, and prices generally lower.

HARVEST TIME.

THE long spell of unsettled weather, a summer temperature below the average, and the sky overcast week after week, have combined to render our expectations of a late harvest a certainty. Writing as we do, however, on the third day of hot, bright, and apparently settled weather, we feel hopeful that, though late, it will on the whole prove an abundant harvest. It is true, as usual, that there are those who take a very gloomy view of the outlook, and predict a great disaster for farmers, but we are not in sympathy with them, and prefer always to take as bright a view of things as possible. No doubt the rain has done harm as well as good. We know of more than one lamentable instance of hay having been

carried away by floods; of Clover and Trifolium seed spoilt by unavoidable exposure to rain after it had reached maturity; of winter Peas sprouting from similar exposure, or falling from the pods from being overripe before it was possible to cart the crop.

We had to break off after writing our first paragraph for a journey by rail and road through West Suffolk into Cambridgeshire and Essex. Of corn damaged by weather we saw very little, but we are bound to mention a large field or two of Square-head Wheat on a heavy land farm on the borders of Cambridgeshire which had suffered somewhat from stormy weather. The crop was a fine one, with large bold ears, and wherever it was at all thin upon the land it had been so blown about by high wind that quite a third of the ears were bruised sufficiently to prevent full development of the grain, and the brown husk betokened checked growth and premature ripeness. Other Wheat, both Red and White, with more slender ears was not so affected, and we could therefore only come to the conclusion that the full, heavy ears of Square-head, being very soft and tender from the humid atmosphere in which they have been developed, were consequently more liable to damage when blown about violently by high wind, and wherever it was a very thick and full crop there was little, if any, of it so damaged.

Barley is generally a fine full crop, and where it is exceptionally heavy much of it is beaten down. There is an old saying that "Laid Barley is made Barley." We hope it may prove true now for we have much "laid Barley." We have seen a little ergot in some fields of Barley, and only a little. Last year, when going through some Barley just before harvest in light summer attire, we had ample evidence of much "smut" among it from the black blotches on our clothes. Barley ears with abortive grains are to be found in most fields, but we have seen none that is seriously so affected.

We saw in our journey several fields of Winter Oats being mown; in every case the straw was so green that it was with regret we saw a self-binder reaper at work upon this crop in one field. Green straw, and a vigorous weed growth among corn, call for caution in binding and stacking corn this season. Our own Winter Oats will not be put into sheaves at all. They are mown into light swaths, left so long enough for the exposed side to ripen, and are then turned over and left till the remainder of the straw is ripe and sufficiently matured for stacking. Spring Oats on many farms which have come under our notice are a light crop, owing, we believe, to poor culture. To have a full crop of White Canadian or Black Tartarian Oats land must be in a state of high fertility, and it will then yield at least twenty sacks an acre. Less than this cannot answer while foreign Oats are so cheap. Winter Oats will be followed closely by Rye, and on light ground by Barley and spring Wheat. We saw some Barley near Cambridge on August 9th quite ripe and ready for the reaper, while at heavy land farms on the same date the ears were quite green.

A close inspection of the crops on many farms has brought conviction that the condition of them generally is very much in accordance with that of the soil in which they are growing. As usual, bad farmers would have us suppose their inferior crops to be an outcome of the season, and that a late harvest must of necessity be a bad harvest. This is altogether wrong, for in this and in every year the crops of the really good farmer are excellent in a very high degree, while those of the bad or incompetent practitioner range downwards in the scale of inferiority very much in proportion to his practice. It is from the latter class that the outcry about weather and crops comes, and we cannot but receive any statement from them, however positive, with reserve. On the whole, then, with fair weather now we may reasonably hope that a bountiful harvest, though a late one, will crown our efforts with a fair measure of success, and that there will be some improvement, however slight, upon the results of last year.

WORK ON THE HOME FARM.

The haymaking was finished in real summer weather, and the last two stacks of hay are excellent both in colour and quality. Taken on

the whole the hay made this season is sound, wholesome, and nutritious, and we require cattle spice or other nostrums to render it palatable. In this we are fortunate, as much hay has undoubtedly been spoilt on the low lands, and in several instances it has been carried off by floods.

The corn harvest has begun, and the work generally is heavier than it was last year from the greater bulk of straw, and also from much of the corn being lodged. The Barley will require especial care owing to an exceptionally strong growth of weeds, and of the plant of layers of Clover, Sainfoin, and mixed seeds wherever they have been sown among it. Oats, too, require much care, for the corn is ripening upon green straw, which requires full exposure and turning at least once after the mowing. Self-binder reapers will not be found so generally useful as they were last season, and the use of them will be restricted to crops sufficiently free from weeds, and with a clean erect growth of straw. As the season is undoubtedly a critical one it is highly important to secure enough labourers to ensure the work being done expeditiously while the weather holds fine, and not to depend overmuch upon implements.

Since the change to finer weather arrears of hoeing among root crops have been taken in hand, both to destroy weeds and to single late white Turnips. Most of such crops are highly satisfactory, and all green crops are remarkably abundant. Maize, though backward, is a full strong plant. Cabbages and Kale are exceptionally vigorous, and are quite free from any suspicion of club root. Tares have not only given a heavy crop, but from winter Tares we have a second growth which is being turned to good account for sheep folding.

Of white Mustard we have some useful fields, some of which have been ploughed in, and others folded with sheep before the ploughing. So far as is possible ploughing is being pushed forward, as with a late harvest we shall have to be on the alert to have the land ready for Wheat sowing in good time. On heavy land we like to sow as much Wheat as we can in September, in order to ensure a stout plant that is well established in the soil before winter sets in.

THE HARVEST.—Russia appears to be the only European country in which a good harvest is expected, though Roumania has reaped a fair one. France has a very defective Wheat crop, and is now in all the agonies of a wet harvest. In Spain and Italy the crops have proved much below average; in Austria-Hungary they are a great deal less prolific than they were last year; and they are below the mark in the west of Europe generally. The American Wheat crop is well known to be a poor one, though not quite as bad as it was at one time expected to be. Harvest is nearly finished in the United States. Estimates based upon some figures supplied by the Department of Agriculture in June, as interpreted by the declared condition of the crop in July, point to a total yield of winter and spring Wheat amounting to about 427,000,000 bushels, or 29,000,000 bushels less than last year's produce. Since July 1st prospects, it is reported, have remained about stationary, so that it is not likely that the out-turn will be in excess of that just stated. Canada, in spite of an extra crop in the North-West, will do little more than supply her own requirements, and may be left out of account in considering the Wheat supply of Europe. The "visible" and "invisible" stocks of Wheat in the United States on July 1st, according to the *Cincinnati Price Current*, amounted to 63,000,000 bushels, or 10,000,000 bushels less than the stocks held at the corresponding date of 1887; 18,000,000 less than those of July 1st, 1886; and still more below the quantity for any other year since 1882. Unless this small reserve is to be diminished, then, it appears that, even without allowing for the consumption of the increase in population during twelve months, and also without taking into account any possible difference in the stocks of flour, the United States will have a smaller surplus by 29,000,000 bushels than the 116,703,330 bushels of Wheat and flour in Wheat equivalents exported in the year ending June 30th, 1888.

REMARKS.

- 5th.—If any rain in early morning, fine day, shower about 8 P.M.
 6th.—Cloudy day, with occasional spots of rain, wet evening.
 7th.—Bright and warm.
 8th.—Bright and warm.
 9th.—Hazy early, bright hot morning, cooler and frequently cloudy in afternoon.
 10th.—Cloudy early, bright hot day.
 11th.—Cloudy and cool.

A fine warm week. The maxima are about 4° above the average. This is only the second week in which, since February, the maxima have been at all above the average. It is many years since the daily maxima have been so uniformly and persistently low.—G. J. SIMONS.

SUBSOIL may be described as the layer of earth immediately below the ameliorated portion, the former not being usually interfered with in preparing the ground for crops with the plough or the spade. In spade husbandry the subsoil may be about 12 inches from the surface downwards, whilst in ordinary farm operations the surface is not stirred deeper than 6 inches. There is, therefore, a great difference in soils as they are operated on in gardening and farming; and there is a difference in subsoils, though some vary little in composition from the surface soil, yet there is generally a great distinction between them in cultural values. The surface or worked soil contains a very much larger proportion of organic matter and soluble food for plants, and though liable to impoverishment by the crops, is benefited by the roots and other parts of such plants as remain after the crop is taken, these decaying, and in combination with applied manures give the surface soil an immense advantage over the subsoil, as it can derive little or no increase of organic matter through the comparative inaccessibility of air and rain. It must not, however, be overlooked that the surface soil is altered in texture by the crops. It is made more open by the roots that traverse it, and its friableness is increased by the operation of tillage. This admits of the freer access of the great solvents, air and rain, insuring a more speedy decomposition of organic matter, or the formation of it, this decomposition causing some of the soluble matter to pass down to the subsoil, which, it is unnecessary to say, is a direct increase of the resources of the soil as it affects the crops. The compounds taken down remain in the subsoil in proportion to its retentive power. They exert influence, useful as food, or for food manufacture out of otherwise inert matter, or are injurious to plants from the lack of the necessary correctives essential to changing the compounds into plant food. Some soils may be almost sterile before they are exposed to air, or they may be of little value for useful crops until the deleterious substances in the subsoil have been changed by the application of some materials, as that of lime to peat or boggy soils, which are impregnated with the salts or oxides of iron. If the subsoil be sand or gravel, or otherwise of a loose nature, the soluble compounds brought into it by rain soon pass away, so that there is less addition of useful food, and it follows, less danger of the deleterious matter being retained. If, on the other hand, the subsoil is clay, it retains what is brought down by rain passing through the surface soil, which may in effect contribute to the soil's fertility, or prove deleterious through retaining the poisonous as well as the soluble compounds that are useful as food for plants. An efficient system of drainage, it is evident, must form the basis of all operations having for their object fitting the soil for a variety of crops, and for making the most of the cultural operations through the changes effected by the free access of air and rain, and to assist in the disintegration of stubborn material, and change the otherwise inert or injurious compounds by the application of corrective material into nutriment for crops.

Subsoil is apt to be overlooked in deciding on the fertility of soils, yet it exerts a commanding influence on the surface soil. When the subsoil is open and sandy it is poor, through its lacking the means of retention of the soluble compounds brought into it from the surface soil by rain, which drains away rapidly, and as evaporation from the surface soil is correspondingly free, the plants

grown thereon suffer greatly in time of drought. It is evident that to materially improve such soil some substance must be employed that will render it more retentive alike of rain and of the manurial matter employed; the non-calcareous by a dressing of chalk or of clay marl, whichever may be most convenient, though the latter would perhaps be the most effective from its adding by the divisibility of its parts to the rooting area and the increased retention of the solvent compounds. It is well perhaps to notify that a siliceous marl is only valuable to a light soil in proportion to the amount of chalk present, and deleterious in relation to the percentage of silica or sand, on which account it is not nearly so beneficial for light soil as the clay marl having clay or alumina as a component part. To effect a permanent improvement, 100 cart-loads per acre, mixed with the soil, but not so as to interfere with its tillage, is a proper quantity.

Some light soils have, beside a sandy or gravelly subsoil, an under stratum of clay, or conglomerated sediment of various earths largely impregnated with oxides of iron, which retains the water to a certain level, and from such Horsetails and Thistles spring strongly and in profusion. Such reservoirs of moisture are of no value, but the contrary, inasmuch as they contain substances poisonous to useful plants through stagnation. The water in such cases must be carried off by drains, so as to prevent its lodging within 3 feet of the surface; indeed all soils should be freed of water beyond their retentive power within 3 feet of the surface by an efficient system of drainage.

Where the subsoil is clay, more or less impervious to water, the rain passing through the surface soil is retained, or otherwise, according to the degree of porosity, and collects in the low places or hollows, stagnation ensuing, forming organic acids in consequence of the absence of air acting on the decomposing remains of previous crops or the remnants of the manures not appropriated by prior crops. The surface soil in consequence is rendered cold, sodden, and sour. Nothing but an efficient system of drainage can render such land for profitable cultivation, inasmuch as other operations are frustrated until the land is freed of the stagnant water and poisonous compounds. The drainage alone will change the nature of the subsoil, as the water dislodged by the drains will be followed by air, and the organic elements will form nitric acid in addition to that brought into the soil by rain, whereby the poisonous compounds will be neutralised and nitrogenised, and food stored in the soil for the support of useful crops.

Clay subsoils should be well broken up. For gardens, whether flower, vegetable, or fruit, the land should be trenched, not turning the top ameliorated soil under one or two spits of stubborn material, but keeping all the workable portion uppermost, the stiff material being kept under, yet disturbed in order to form passages for the free percolation of water through it, and to insure cavities for the storing of air, moisture, and warmth. Although the ameliorated soil should be kept at the top, some of the under layer may be brought to the surface, as such contains substances required by plants that have passed into the subsoil, leaving the surface more or less exhausted. It is a direct means of affording new soil, which, exposed to the atmosphere, pierced by frost, or baked by sun, becomes pulverised, mixing readily with the bulk, enhancing its fertility. There is the still further advantage of increased depth for roots, whilst the blending of the manures with the new soil improves the whole considerably, a larger food being provided and furnished with sustenance for crops.

Perhaps the greatest effect next to breaking up a clay soil is to burn some of the stubborn material; this alters its texture, rendering it more open, consequently more permeable to air, water, and the roots of plants. Its affinity for ammonia is also increased, and a much greater proportion of soluble alkalies, especially of potash and soda, provided; but that depends in a great measure on the degree of burning, for if hard burned the clay will be of the nature of bricks, and its alkaline constituents are then less soluble than of

the clay in its original state. The most that should be sought by burning is that the clay may readily crumble. In that state 100 cartloads per acre is a fair dressing, applying it to the surface, and it will render a good account of the ammonia within reach, absorbing it from the atmosphere and from manures or by whatever means supplied. In the case of very stubborn clays it is advantageous to mix some of the harder burned particles with the stubborn material at the bottom of the trenches, by which means the permeability of the soil to air, rain and roots is made more durable, acting alike as a storehouse of moisture and food, from which the crops can draw supplies in times of drought, the roots being attracted downwards by the moisture they inadequately receive at the surface, and as they must in due course decay they tend to open the soil to a greater depth and supply organic matter for its enrichment. In that way soils which have only a thin layer of ameliorated soil can, no matter how stubborn the subsoil, be deepened, and in the course of a few years so much so that the ground can be trenched two or three spits deep, blending the whole mass with very great benefit to the crops. What most land needs is new soil brought to the surface to be ameliorated and enriched by the action of light, air, and rain, pulverised and made workable by frost or sun, in which state the soil derives the greatest benefit from the solid manures applied, and the whole staple is permanently improved.—G. ABBEY.

GRAPES SCALDING.

WHEN theories become firmly established it is very difficult to eradicate them. If we could obliterate the notion that scalding is constitutional then I am convinced we should hear considerably less of this evil than we are in the habit of doing. My object is to show that scalding is not a defect in the constitution of any variety of Grapes, and one is no more liable to be attacked than another; but that it is due to the system of culture pursued, and can by care and forethought be prevented or mitigated. If we were to conclude that scalding is constitutional with Lady Downe's we should be compelled to place other kinds in the same category. It is no more difficult to scald the berries of Black Hamburgh and Madresfield Court than those of Lady Downe's, a variety perhaps more subject to this evil than others. There is no doubt whatever that the constitutional theory has come into existence because scalding has been more prevalent in late than early and second early houses, but this is explainable.

It may be well perhaps to give the reason why late Grapes suffer more from this evil than those forced to ripen early in the season. It is because the sun, when the former are passing through the stoning period, has considerably more power over a longer period of the day, and there is generally much greater extremes between the day and night temperature than is the case when Black Hamburgh and others are passing the most critical stage of their growth several weeks sooner—in spring instead of summer.

It must not be concluded that the sun alone is to be blamed in the matter. My proposition is that it is the source from which the mischief springs when cultural requirements are defective. Irregularity in the temperature, such as extremes between the day and night, or even extremes during the day, will play a very large part in bringing the evil in question into existence, or aggravate it when it exists. Scalding is liable to take place just as the stones are becoming hard—in a word, when they are in the last stage of perfecting themselves. Over-forcing, whether due to an increased temperature by sun heat or the anxiety of the cultivator to push the crop forward when Nature requires to move slowly, will certainly end in scalding, to a greater or less extent, according to the amount of forcing to which the Vines may be subjected. The hottest sun during the day will do no harm provided liberal ventilation is given, and I would much sooner have a continuance of hot bright weather to deal with during the stoning period than such weather as we have had this year.

I have suggested that scalding is brought about by the cultivator, and hence may be to a large degree prevented. In nearly every case, in the majority of seasons, this evil is due to defective ventilation early in the morning or after the routine closing time in the afternoon. Scalding nearly always occurs where the morning or afternoon sun strikes directly upon the house when it is closed. Suppose the east end of a house has one fixed light, or the top ventilators do not open to the end, I venture to assert that unless the necessary precautions are taken the berries will scald badly whether the Grapes are Black Hamburghs or Lady Downe's. Even

when the ventilators open to the end of the house the bunches exposed to the sun are not generally safe from this evil. The same will take place at the west end of the structure when it is exposed to the sun in a like manner. It is possible that the berries will scald in these two places when there will not be the slightest trace in any other portion of the structure. The midday sun does no harm provided the house is freely ventilated, but subject the Grapes at this critical period to the same conditions as the east and west portions of the structure, and scalding will be the result. If I may use a homely illustration, the Grapes in the east and west portions of the house are practically in a stew-pan, and when the temperature of the whole house is allowed to run up to 80° or 90° before it is ventilated, the Grapes throughout the greater portion of the structure are subjected to the same trying ordeal. Those nearer the base have the best chance, and often escape without serious injury, while those in the highest position are certain to fare worst. Who can expect Grapes to come out of a stew pan in the same condition as they were before they were placed in? It is impossible, and in like manner those who neglect to ventilate until the moisture in the structure become overheated must expect scalding, while those who allow the escape of moisture early in the morning or leave air on those critical positions all night need not fear being troubled with the evil I am writing about.

Air at the base only is not sufficient to guard against this evil. A "chink," however small, should be on the top as well—that is, in the east corner, while the light, or ventilator of the west end, should not be closed before the sun is sufficiently low to be harmless. If this is done the Grapes in these two positions will be safe from scalding, as will also the remaining portion, if air is admitted at the top at 6 A.M., instead of one, two, or three hours later, as the case may be. Even the admission of air is not always ample, for I have known the berries scald in the bunches exposed to either the morning or afternoon sun through the ends of the house. These can be protected by shading them with whitewash, which can be removed after the Grapes are fairly well coloured, or if left on until they are ripe it will do no harm. There are plenty of old houses still in existence where the top portion of the lights slide down, and in many instances I have noticed a light at each end and a fixture. The admission of air at the light adjoining the fixed one is not ample to protect the Grapes under the fixed one. I have proved this to be the case, but if the exact position where the sun strikes early and late is lightly whitewashed not a berry will be lost.

This has been a trying and peculiar season, and has considerably taxed the experienced grower. It has been most difficult to know how to ventilate to prevent great extremes in temperature even in the short space of an hour. Grapes during the day have not been subjected to such irregularity from natural causes perhaps for very many years, and this is the reason that scalding is so prevalent. When Grapes reach the stoning period the safe course is not to hurry them, but give them time and strive to maintain a regular temperature. This is best accomplished by slightly raising the night temperature and ventilating on the most liberal principles during the day, so as to bring about a nearer approach to uniformity between day and night. When the evil makes its appearance the only chance of mitigating it is to be careful that the conditions that brought it about are not repeated. The night temperature should be raised to 70° or even 75°, according to the weather, and the house ventilated early and late, while during the day it should be ventilated on the same principle as a greenhouse.

Those who have scalded Grapes this season are largely excusable, but in good and average seasons there is but little excuse for those who fail from this cause, because it is mainly due to negligence in ventilating the structures in which they are grown.—WM. BARDNEY.

RUBBISH HEAPS.

AN "old hand" of the gardening fraternity once said, "Show me the rubbish yard and stokehole of any gardener, and I'll tell you within a little what sort of a gardener he really is;" yet however good his judgment may be where such conveniences exist, he would have to found his opinion upon some other basis in endeavouring to sum up the abilities of the man who has "no rubbish heap." Most gardeners are in a favour of a rubbish heap, or a fire, as the refuse from the latter is of considerable value from a manurial point of view, while in the case of heavy holding soils the free use of such refuse is of the greatest possible help in bringing the soil into proper working order. Some time since I observed an instance of the "no rubbish heap" principle, and it may be worth recording. The accumulation of rubbish in large and small gardens goes on at an alarming rate, and, if not methodically dealt with, soon becomes an offensive pile. It was with a view to avoiding the disastrous consequences arising out of the latter that the rubbish

heap in the instance before us was abolished. The garden where this is carried into effect is of considerable size, and forms part of the grounds of the Metropolitan and City Police Orphanage at Twickenham. Consequent upon the number of orphans who are cared for at this excellent institution, precautionary measures are freely employed to prevent the outbreak of disease. It is with this object in view that Mr. Gardiner, the superintendent, has studiously avoided a rubbish heap owing to the impure vapours which arise from such during fermentation and decomposition. A deep trench is formed across one of the quarters in the kitchen garden, and the garden refuse as made is deposited in it and covered with a sprinkling of soil. When the trench is sufficiently full it is covered in, leaving another by its side; this in time is served likewise, and so the operation continues till the whole quarter has been traversed. By this process the soil receives a good dressing, and is thoroughly trenched into the bargain, the ground being cleared and cropped as the work proceeds, so that at all time will there be any great amount of land unoccupied. The plan answers admirably, and excellent crops are the result. Nothing is simpler or more effectual, and may be adopted in most gardens, thereby dispensing with the unsightliness of the rubbish heap, which in some cases amounts almost to a nuisance.—J. H. E.

A CHAPTER ON FAILURES.

I AM glad to see that much of my advice is verified by practical men, and maybe some of your readers may be inclined to think I have no failures; but I have, and, further, I never knew a gardener who had not. I have been under a few good ones. I have seen the work of others in many parts of the country, and in all cases I found failures; some, it could be seen, would not own to them, while others, and these generally the best gardeners, made no secret of them. Indeed, the plants which come under the care of a gardener are so numerous and varied in their requirements that no one who considers the matter fully need be surprised that they should have failures, and the wonder is they have not more. But probably the reason some are afraid to own to their failures is because their employers do not expect them and make a disagreeable fuss when they occur. For instance, I have known some employers visit nurseries and buy the most tender and rare kinds of plants when they had no proper accommodation at home for them, and they could not possibly receive the same treatment as they were receiving in the nursery, the result being that they died or remained sickly; but although this might be regarded as a failure by some it is unreasonable to blame anyone for it, more particularly the gardener, who is unfortunately connected with the case. I have also known garden owners so much charmed with Muscat Grapes that they did not feel satisfied until they had planted some, but as their houses were only fit to mature cool-growing Grapes the Muscats were not a success, and culture was thought to be deficient. I am, fortunately, not referring to myself in these cases, as I have a reasonable employer, but I could tell of those to whom the remarks apply.

Some years ago I had a capital stock of *Calanthes*. They were potted in the spring as usual, but they were overwatered before they had formed sufficient roots, became sickly, and it was two years before they recovered. Orchids bring many failures, and this, I believe, is why they remain so expensive and the demand for importations never lessens. I have killed many. I once had some *Masdevallias* which I hoped to improve by placing them in a little extra heat, but it did not agree with them. Some of them died, and none was improved. Early Carnations are wanted with us. One autumn we lifted a number of layers from the open borders and planted them in the bed of a conservatory. They existed and grew a little, but they were a long way from the glass, and in a good deal of moisture, and although they produced flowers some weeks before they would have bloomed in the open, the blossoms were small, and the plan was not a success. *Maréchal Niel* Roses are favourites here. We have tried them in many corners under glass to obtain them early. Two or three plants that were placed in the bed of a Cucumber pit with bottom heat and a close atmosphere to urge them on made huge growths, but never produced flowers worth looking at. Several Peach trees were planted in the open in deep heavy soil. They tried to grow, but did not, and after two years they were dug up, given to a cottager, planted in very shallow soil above ample drainage, and at the present time they are pictures.

Mealy bug is an enemy we have had to contend with. Through growing all sorts of plants in a vinery it attacked the Grapes. It was eradicated, but not without failure. A well-recommended insecticide was put on so strongly and freely that it burned the skin of some of the young green berries, but the bug was hardly injured. A year or two ago a new insecticide was received. I had

no experience of it, but I trusted to the advice of others, syringed a few Peach trees with it according to directions, and in less than a week half the foliage had fallen.

Sensational crops are always seductive; more than once I have allowed double the number of bunches to remain on the Vines than ought to have been left, and the result almost invariably was small berries and poor colour. One year I thought to still further improve our good Celery by earthing it up with finely sifted ashes. The sun in July and August made the ashes so hot that they scorched the leaves and stems and the plan was a complete failure. Extra fine Vegetable Marrows have been expected more than once from plants grown in little else than manure, and most luxuriant growth with a few badly formed fruits followed. We have sown early wrinkled Peas in trenches early in spring, when three parts of the seed perished by cold and wet, and little failures of this kind have occurred with other vegetable crops.

Conditions of weather and other circumstances have so much influence over all the gardeners' live stock that I hold it is impossible to go on without failures; and although I am strictly in favour of trying the utmost to avoid them all, should overlook them so long as they are not too numerous and severe. In gardens where failures are the rule the cause is obvious, but where they are the exception and occur chiefly by trying experiments to improve the condition of things I would exempt all connected with them from blame.—K. G.

CABBAGES—A CRITIQUE.

I THOUGHT at the time of reading the bold assertion of "A Kitchen Gardener," on page 90, that it would "never answer" to sow Cabbage seed early in July, someone would show he was in error. Had your correspondent been content to say early July sowings had not answered with him he would have been on safe ground. He appears to have ascertained "without doubt" that the last week in July and the first week in August is the best period for sowing. That may be so in his case and many others, but it is not the best for all varieties, districts, and purposes. I have seen *Ellam's Early* command higher prices in the market, the plants raised from seed sown early in July, than I ever expect to see any larger and later sorts realise when sown as advised by your correspondent; and if that is not a test of merit both as regards a variety and time of raising I do not know what is. The value of Cabbages depends on their earliness, not only for market but equally so in private gardens, and in the latter small Cabbages are usually preferred; moreover, as two of these can be grown in the space required by one of their larger congeners, the smaller are the more profitable. Sow the true *Ellam's* about the 10th of July very thinly, so that the plants do not touch each other till they are large enough for planting, and not one out of a hundred will bolt; and I shall be surprised if any of the large varieties sown with *Ellam's* now, at this late period, will equal it in the spring.

Although "A Kitchen Gardener" writes with much confidence, his communications suggest that he has still something to learn, even on Cabbages and their culture. He has nothing, however, to learn in the art of laudation on the one hand or condemnation on the other, according as a variety may please him or the reverse. There is no shading in his word-painting, and black or white appear to be his favourite colours, first one and then the other predominating, as he is disposed to "lay it on." He condemns the *Early York* Cabbage in his bold way, for he says "it will never be a favourite again." "Never," is rather an awkward word to use in that sense, as it has a bearing, not on illimitable time only, but on numberless persons, for it means, if it means anything, that the variety can never become a favourite with anyone. I am on quite safe ground in saying he is wrong there, for it is a favourite of mine, because it has served me and others well. It is condemned on page 90 because it "bolts." May I venture to submit that the variety is not so much at fault as its judge? "A Kitchen Gardener" sows his *Early York* at the wrong time, and if he will sow at the right period he will have a different result.

I can scarcely understand a person learned in the art of Cabbage growing by years of experience sowing *Early York* in the autumn. It should be sown in the spring for use in the autumn, not sown in the autumn for use in the spring. I do not hesitate saying that until a grower has raised plants of it in April and May for use in the autumn is in a position to give a true verdict on the variety. Like your correspondent I have even grown from "twelve to eighteen" varieties of Cabbages, and probably more than twice the number, and I have this to say about *Early York*, that will "never" be in favour again, that I know not one out of all the twelve that excels it for late autumn use, not one that has given more satisfaction to, well, not bad judges of what is good. Have it in at the right time and the best condition, and it surpasses *Coleworts*, renders *Savoys* coarse by comparison, and is preferred even to

Brussels Sprouts by at least half the persons who have their share of both. So much for the sweeping "never," and I suspect the condemned culprit will be grown more than ever next year.—
A YORKSHIRE CABBAGE GROWER.

BLUE DISAS.

BLUE Disas have been mentioned in the horticultural press more frequently than they have been seen flowering in this country, but one of them, *Disa lacera*, is now flowering in Mr. A. H. Smee's collection at Hackbridge Grange. It is one of Mr. O'Brien's introductions, and it is on his authority that Mr. Smee's gardener, Mr. G. W. Cummins, supposes it has not flowered in England before. The plant is in a 3-inch pot, throwing up a straight thin wiry-looking stem about 18 inches high from the tuber, the grass-like leaves withering before the spike appeared. The flowers, of which there are four or five, are about an inch across, and of clear cerulean blue, with a small lip, fringed, and much darker in colour. It is an attractive novelty. Several new Disas are grown at Hackbridge, and they are found to succeed best on latticework supported a few inches above a stream of water overhung with trees in the garden. The pots and roots are there constantly damp and cool. *Masdevallias* and several *Odontoglossums* appear to enjoy the same treatment, but thrips do not, a consignment of plants much infested with these insects being now quite clean and rooting freely. Several new Disas from very small tubers are being established in a cold frame in a shaded position, the pots stood on others in large saucers of water. These plants do not thrive in any of the houses, because they are not sufficiently cool at the roots and the air surrounding the pots too dry.

THE LYCASTE DISEASE.

Many growers of *Lycastes*, notably of *L. Skinneri*, have been troubled through the pseudo-bulbs of the plants gradually decaying, the disease appearing in the form of small dark specks, which enlarge till the entire tissue is destroyed. This having occurred in the collection above noted, an analytical chemist prepared a transparent liquid, resembling water in appearance, but in smell most offensive, which Mr. Cummins was desired to try on an infected plant. One of *L. Skinneri alba*, thought to be incurable, was chosen, and the liquid applied to it with a camel-hair brush. The malady was at once checked, and now a pseudo-bulb perfectly clean and healthy has sprung from those unmistakeably diseased, and the bad and good in the same pot cannot be mistaken. It is a pity there is no Tomato disease at Hackbridge to which the innocent-looking liquid could be applied, or there might be a chance of making the promised fortune. Perhaps Mr. Iggulden might like to try it, since he tells us that Dr. Masters' proposed remedy has failed; not that our Tomato authority wants to make a fortune—that would be no novelty to him—and he would only be too glad to make a remedy for the Tomato disease known to the world.

THE COMMERCIAL REALISATION OF FRUIT.

(Continued from page 145.)

A MARKED feature of the value of fruit crops is largely lost sight of by all home growers, and that is the deterioration that takes place in the flavour of fruits owing to the delay that takes place, and the treatment they are subjected to in their transit to market. The quality of the crops that occupies an inferior position, owing to this circumstance, is something incredible. Most of this, if properly dealt with in the vicinity when gathered, would retain its freshness and flavour, and consequently its value. These and many other advantages can only be ensured by commercial co-operation, which may be acquired if the fruit farmers of a district will combine to place their crops at their own general disposition for joint realisation in the most suitable manner that local circumstances pointed out. If this were done to a sufficient extent I know that efficient commercial assistance could be secured for all purposes—viz.,

1st, To supply all the facilities necessary for the purpose of dealing with the crops in the most advantageous manner.

2nd, To organise an outlet for the fruit in every possible direction, and arrange for its direct despatch to retailers from the farms or centres of collection, so that expenses may be saved and loss of time avoided.

3rd, To form and register local societies for the producers of each parish or district, and to establish a central society in London, in the management of which they will take part and control so far as the conduct of their own business operations requires.

4th, Arrange for the provision of the necessary funds for the local societies to make payments on account to the growers upon the delivery of their fruits, pending realisation.

5th, Provide the plant, machinery, and utensils of trade, necessary and requisite for all the operations, to effectively and profitably prepare the crops of fruit for realisation as may be determined upon.

6th, Select the skilled and practical labour necessary to the various operations, and arrange for the working and supervision of the business details.

7th, Establish and provide the London office with its furniture, fittings, and clerical staff, &c., and organise the direct sale of fresh and preserved fruits to retail traders and shippers.

8th, Provide the requisite advertisements, printing, books, stationery, postages, telegrams, travelling expenses, and other disbursements of and incidental to the business operations.

The commercial arrangements referred to as necessary for the effective preparation for sale and the utilisation of the fruits, their sale to the trade, for the public, and the organisation of a systematic system of speedy distribution, all of which measures are essential to ensure successful results, among other things include—

(A) The sorting, classing, and packing of fresh fruits into small boxes for effective transport, and properly marked and branded for ready sale.

(B) The provision of cold stores and cold storage chambers in vessels and railway carriages, that fruits, immediately they are gathered, may be cared for and maintained in a fresh condition by being kept in a cool temperature until they reach the retailer.

(C) The arrangement of details for the shipment of fruits to the Continent, India, and the Colonies.

(D) The formation of the establishment for the evaporation or drying of fruits, and the creation of a demand for them by the public.

(E) The arrangements for the preservation of fruits by their manufacture with sugar, while fresh, by crystallising, candying, and other processes for the preparation of dessert fruits and sweetmeats.

(F) To provide for the preservation of fruits by bottling and canning in various forms for dessert and cooking purposes.

(G) The formation of the factory for the pulping of fruits, and their preparation and ultimate sale to manufacturers for conversion into jams, jellies, &c.

(H) The arrangement for the manufacture of jams, jellies, fruit butters, marmalade, and other preparation, and the arrangement for their sale in the home and colonial markets.

(I) The establishment of a system of standard qualities and qualifications, coupled with registered trade marks and brands, that home-grown produce and its quantities may be prominently known in the markets, to the trade, and by the public.

The above conditions are absolutely requisite and necessary to enable fruits to be beneficially realised, they cannot be effectively carried out by any one grower, or even by a body of growers, unless they are possessed of a larger amount of commercial knowledge than is usually found among farmers who, as a body, give all their time and attention to totally different matters.

The sound, practical, and legitimate course for producers to pursue is for all within a reasonable district to co-operate with each other for the realisation of their crops in connection with one central organisation, which would undertake the whole of the commercial duties pointed out, and take upon themselves all the financial responsibilities and risks, and receive as their remuneration and repayment a portion of the amounts received for the produce. From this combination of agricultural, industrial, and commercial experience the highest results might be looked for, inasmuch as the members of the local organisation would manage the preparation of their own produce in a definite and systematic manner, of which they would be from time to time informed and advised, by which they would control their expenditure, and keep it at the lowest limit. While they would have the benefit of an organisation for the sale of their produce, whose importance and effectiveness would grow with the increase of the local societies—and who instead of deducting as at present certain fixed sums, irrespective of the amount realised, which at present sometimes absorbs all, and very frequently nearly all, the proceeds of the amounts received for the fruits, while the organisation would be content to receive a portion—say one-fourth—of the amount received for the fruits as their payment and recompense, thus leaving with the growers at all times a very large proportion of the amount realised.

BATTERSEA PARK.

WHEN this and other of the London parks passed to the control of the Metropolitan Board of Works some fears were entertained that the change would not be to their advantage. It is gratifying to perceive that not only is the popular park under notice well maintained, but great improvements are in progress, and others in contemplation. The whole of the glass structures provided for raising and preserving plants are undergoing thorough renovation, this involving a cost of upwards of £3000. Another great work to be undertaken is the cleansing of the lakes, and a deep and large culvert is being made to empty them into the Thames at low water, and fill them at high tide—an important provision and distinct permanent improvement. The houses have been allowed to fall into a most dilapidated state. They do not appear to have been painted or repaired for years. The late Superintendent was evidently the victim of State parsimony to an extent that the public could

scarcely anticipate in respect to the structures, and he must consequently have worked under great disadvantages; indeed, it seems little short of miraculous that so many plants should have been raised and prepared in such tumbledown buildings. They were a disgrace to the nation, and the present authorities have substantial cause for complaint in having to take them over in such a deplorable condition. So much has to be done that it seems difficult to see how the work can be completed for the reception of plants in the autumn, and it will be fortunate if grave inconveniences are averted, and in that respect the outlook is not cheering.

Battersea Park, indeed all the parks and open spaces south of the Thames, are now in charge of Mr. F. I. Coppin as District Superintendent, Mr. Cochrane of Finsbury Park being similarly responsible for parks and gardens on the north side of the river, including those on the Thames Embankment, resident foremen working under the respective superintendents, who, it will be perceived, occupy important and responsible positions. Mr. Coppin has upwards of 200 men under his charge, and only an active, quick-sighted, clear-headed business man could keep them and the work well in hand over such a large area. He was formerly the manager of Southwark Park, developing qualities that fitted him for his present position. Many changes have been made by the Board in the workmen, but the experienced foreman, Mr. J. Hart, remains at Battersea, and Mr. Coppin will find in him a valuable coadjutor. He has been employed in the Park nearly twenty years, is acquainted with every nook, plant, and tree in it, and apt in carrying out details of work.

The superintendents and managers of the parks are fully impressed with the good influence they exert on the minds of visitors, and do their utmost to render them agreeable to all classes. They strive to make the flower gardening worthy the inspection of persons of wealth and taste, and like to see the workers enjoy themselves in the open spaces, also take interest in the cultivation and tasteful arrangement of plants. As an example of the popularity of the London parks, the visitors to sub-tropical garden in the one under notice were counted on three consecutive Sunday evenings two or three years ago, the numbers being roundly 67,000, 68,000, and 71,000. This represents a detachment only of the London public, and all the other parks would have their contingents, some more and some less, at the same time. What would become of the people of London if they had not such pleasant health-giving resorts is not a pleasant thought to dwell on; and no money is better spent than that which is judiciously applied to the maintenance of the London parks and gardens, and it is hoped the time will never come when they will be neglected.

As to the appearance of Battersea Park this year, it has been, like other parks and gardens, unusually green, but has brightened up astonishingly during the past week. The Zonal Pelargoniums are overgrown, and cannot be dazzling. An old soft scarlet variety, Montrouge, is one of the most satisfactory. Begonias quite surpass them in effect, and of these there are good beds. It is a pity there were not many more Violas, for some long lines are masses of flowers, while large beds of them intermixed with the silver variegated Pelargonium Manglesi are amongst the most pleasing of all. It is surprising to see how good and well filled the beds of Coleus and Amaranthus melancholicus ruber are margined with white or yellow edgings. Iresines have been starved, and Petunias nearly washed out. Gazanias have answered well, and groups of Fuchsias are attractive. Lobelias have passed through the rainy ordeal almost better than could have been expected. Sub-tropical plants are late, by far the finest, if they may be so described, being a colony of Brugmansias. Yuccas are throwing up their stately spikes, one fine old specimen having five of them laden with ivory white flowers. The Palm and Fern dell and vista are most tastefully furnished, visitors being compelled to linger over the groups of healthy and elegant plants.

Carpet beds are well filled, Alternantheras assuming the rich glow that constitutes their charm. There is much less of Golden Feather than usual, the best yellow cushion plant in the panels being the Golden Spergula, while the Golden Chickweed is one of the worst. It is neither particularly good during a wet season or a dry one. It is unreliable, as is Sedum aere elegans, S. glaucum being far more constant and pleasing. The mixed beds are attractive, the large scarlet blooms of Hibiscus Cooperi in one of them causing many an onlooker to wonder what it can be; and for some time the most effective of the wilderness plants has been the double-flowered Bramble. Funkias have grown well and flowered freely, the wet season having evidently suited them. The diversified character of the park renders it enjoyable, and with a bright autumn it will remain attractive for a considerable time.

A great work requiring to be done is the regulation and thinning of trees and shrubs. They are fast growing into a thicket in many places, spoiling each other, and must get worse year by year if relief is not afforded. Yet it is necessary to proceed cautiously in the work in public parks in which so many inexperienced persons are interested, for it is pretty well understood that those who know the least make the most noise in fault-finding. Of this no persons are more fully aware than the managers of the enclosures, hence they strive to effect improvements gradually—it may be too cautiously in the interest of the trees—without provoking opposition.

ABUTILON VITIFOLIUM.

LAST year a correspondent in Cornwall sent us a note upon this beautiful Abutilon, in which he remarked that he had "a specimen

14 feet high and 32 feet in circumference at 6 feet from the ground, growing out of doors in a position sheltered from the north-east and west, where it flowered most abundantly every year." Very rarely are such examples seen out of doors, and it is only in favoured climates like the west of England or some districts in Ireland where these results could be expected. In most cases where it is found in gardens it is an inmate of the greenhouse, and very seldom can an adequate idea be then formed of the beauty of the shrub when fully developed. The flowers are large, of a delicate purplish or bluish mauve, not unlike the stately Meconopsis Wallichii in tint and form. They are produced in great abundance, and in contrast with the large dark green lobed leaves they have a fine appearance. A small spray is represented in fig. 18, but our artist has not caught the characters of the plant with his usual facility, as his specimen suffered in transit. Messrs. Kelway & Son,

FIG. 18.—ABUTILON VITIFOLIUM.

Langport, recently showed some specimens at one of the Royal Horticultural Society's meetings, when a first-class certificate was awarded for it as a half-hardy shrub.

DEGENERATION OF FRUIT AND VEGETABLES.

[A paper read before the Massachusetts Horticultural Society by Mr. O. B. Hadwen Worcester, U.S.A.]

(Continued from page 95.)

CONTINUING the discussion on this subject, Mr. William H. Hills of Plaistow, N.H., said that the topic was exceedingly interesting. He had made many observations in regard to it. Some think that the Rose Potato has degenerated, but we get them from Aroostook county, Maine, as fine as ever. When it was introduced he bought 2 lbs., and from that quantity he raised 240 lbs. He cultivated them like others, with a light dressing of manure over the surface, except that for the Rose he added a handful of superphosphate in each hill, and he

thought he could get as good results to-day. Sports are difficult to account for; on the May Duke Cherry trees there are every year branches where the fruit is from ten to fourteen days later than on the rest of the tree. There are certain conditions that we cannot understand. Last year he felt some alarm lest the Baldwin Apple was degenerating; his were small, but he found they were as large as anyone's. His early Apples were as large as ever, and his Russets never were finer. Something that we could not perceive had affected the Baldwins. It frequently happens that something which we cannot account for injures a crop.

Disease is distinct from degeneration. The Flemish Beauty Pear cracks; is this degeneration or disease? He notices the cracking of Apples more every year; the wound seems to heal inside and they seem to recover, but the fruit is still worthless; he thought this was disease, but could not tell what produced it. The fruit of the Baldwin Apple trees that were on his land when he bought it is different from that produced by the trees he has planted. There is no fixed type of this Apple, but in propagating he has always taken his grafts from trees bearing yellow fleshed fruit. A Grape Vine climbed into one of his best Baldwin Apple trees and ruined the fruit by causing it to mildew, but he has cut away the Vine and expects the fruit to recuperate. The modes of cultivation and peculiarities of the seasons are continually affecting fruit. Of sixty or seventy varieties of small fruits described a few years ago only four are in cultivation now.

Mr. E. W. Wood said that the question of degeneration had been much discussed, but no one could deny the fact, whether he attributed it to disease or other causes. He thought the essayist's comparison of vegetable with animal life might have been carried further. Man adapts himself to changes of climate by changes of clothing, and if we could do the same by trees we might be sure of good crops everywhere and in every season. Cultivation under glass effects this result, and hence Peaches in houses retain their health and produce regular crops. He did not agree with Mr. Hovey in regard to the Peach, but thought we cannot cultivate it as formerly. His recollection is that for a series of twenty years the crops were as regular as those of Pears are now, or those of Apples every two years, but if we attempt to cultivate the same varieties to-day we find a marked difference. He felt sure that plants do suffer from continued propagation by grafts or cuttings; he has grown remarkably strong Verhena plants from seed, but they soon ran out when propagated by cuttings. The Hovey Strawberry was perhaps more generally grown in New England than any other variety thirty or forty years ago, and there is no better kind now if we could grow it, but we cannot. Mr. Hovey's own specimens are not up to the standard of twenty-five years ago. In later years the Wilson has been more generally grown than any other kind, but it is now being discarded. Mr. Hovey said that he had seen Crawford Peaches sold for a dollar and a half per dozen, and he had seen a basketful sold for the same money. In 1807 Judge Peters said he had an orchard of two hundred Peach trees, and he complained that they were subject to disease and decay; and that for forty years they had been short-lived. This was near Philadelphia. Further south and in the western country and in some parts of New Jersey they were durable and productive, as they had formerly been with him. The subject before the meeting is not degeneration in Massachusetts, but everywhere, and it should be remembered that this is not the native climate of the Peach. The varieties are as perfect as ever. Dr. Van Mons's theory of producing improved varieties of fruit was by beginning with the wild species and sowing the seed through successive generations; but anyone would be called crazy now who should begin with the wild *Fragaria virginiana* to improve the Strawberry. He asserted that after several generations as good Apples could be got from seed as by grafting; but the Seckel, Sheldon, Fulton, and all other fine native Pears have come from cultivated varieties. There may be degeneration of culture, and we should be very cautious in attributing its effects to the degeneration of varieties.

Mr. Hadwen said that the fact of degeneration is not changed because we can point to some of its causes; but what has become of the old varieties? We cannot tell how long varieties can be made to exist; we may graft on vigorous stocks, but even then the period of existence of varieties is unknown. Mr. W. C. Strong objected to the term "degeneration;" he would say "liability to disease;" the instances quoted seem to militate against the use of the former word. The Flemish Beauty Pear has not degenerated. In some sections as fine specimens of this variety are still produced as were ever seen. So also in some sections of the country the Peach is as vigorous as ever; so is the Keens' Seedling Strawberry in England. Trees are sometimes invigorated by grafting on stronger stocks; the Magnolia is an instance. The question is whether the tree has become more exposed to disease than it once was. The cracking of the White Doyenné Pear may be caused by the soil having become exhausted of some element or elements necessary for its perfection.

Mrs. H. L. T. Wolcott asked, Could not the same Power which has limited the life of man to threescore years and ten have limited the life of trees also? Fruits and flowers certainly have gone out of date. There may be a consciousness of old age on their part.

Mr. Hovey said that plants were endowed with the power of perpetuation by grafting, which had not been given to animals. The Camellia was introduced two hundred years ago, and the Old White Camellia is the same as ever. Varieties do continue; the Windsor Pear is still good in England, though nearly two hundred years old, and there is a tree of the old Summer Bon Chrétien at Mount Auburn as good as ever.

Mr. George Hill said that he had cultivated hundreds of varieties of Strawberries, and they have always degenerated and gone by, until now he cultivates only one variety, the Sharpless. Tomatoes also have run out; the plants would blast. As good plants as he could raise of the Boston Market Tomato have blasted; the newer varieties are less subject to this disease. Hybrid vegetables will degenerate unless they are carefully cultivated, and the seed is carefully selected; and this tendency seems to be much stronger than the tendency to improve. Old seed is better than new which has been allowed to run back.

Mr. Strong thought the deterioration of vegetables propagated by seed might be due to close fertilisation. What Mr. Hill had said about the Boston Market Tomato suggested this point. Darwin's view was that cross-fertilisation always gave the strongest plants. The effects of this method of propagation should not be confounded with those of grafting and budding.

Mr. Hills said that many of our improved varieties are more tender than the old ones, but the old varieties, once so highly prized, would not taste so good now as they did when we had no better. The further we get from a state of nature the tenderer they seem to become. We have a cultivated class of children as compared with those in the alleys of our large cities; are the former degenerated? It is the same with cows; the improved breeds are more tender, but they are not running out. Grafting on seedling stocks is surely changing varieties, though not perceptibly in one year.

ROSE SPORTS.

THE announcement by Messrs. Keynes, Williams & Co. (p. 119) of a dark sport of Marie Finger Rose is interesting, as sports, to the best of my recollection, have generally a tendency to come lighter than the original. A Marie Finger of the colour of Duc de Rohan might well be useful, if distinct from Comtesse d'Oxford; but we have now some close gradations of colour in this class; and it would be difficult to get in a new shade between Pride of Waltham, Marie Finger, and Marguerite de Roman.

A general discussion on the subject of sports would certainly be interesting, and might possibly become valuable. We are not content nowadays to let Nature keep any secrets which we can worm out of her. Nothing would be so likely to solve the mystery of the cause of sports as contributions from the experiences of a large number of observers; and if we could only cause or influence sports, we might perhaps be able to make a good many improvements. But, as matters stand, it seems likely that same useful sports, especially in the gardens of amateurs, are neglected and allowed to perish by not being watched for and propagated.

Some years ago I had a very curious sport of Gloire de Bourg-la-Reine, H.P. The bloom was perfectly globular, and like a Dahlia, every petal being quilled. The colour was that of the type, but shaded darker. So globular was it, that it was not an easy matter to say between which petals the eye was situated. I cut it a day past its best, and took it to the Norwich Show; but the morning was hot, and when my box was opened it looked faint and flabby, and was not shown after all. I was afraid that it would be looked upon as a monstrosity, and that I should lose points by it. I did not think much of sports then, did not propagate it, and a fortnight later left for a new home, and never saw the original plant again. Alas! for lost opportunities, it might have proved constant and good, and a new departure in form. Mrs. W. R. Raillem might by now have been a great success. I have learnt a lesson, but may never have such another chance.

Most rosarians have probably had sports of some sort. One year I budded several Briars from a single long shoot of Abel Grand without noticing anything particular about it. But all these plants proved to be of an entirely different habit from the original, the shoots were very long, and had entirely lost the well-known robust habit. It was a sport, which might, no doubt, have been called "Climbing Abel Grand," but, though these "climbing" sports may be of use to some people as pillar Roses, I did not want it, and purposely did not continue it. The blooms were like the type, but a little smaller, as is often the case in "climbing" sports.

I have at the present moment a strange sport of Marie Van Houtte in my garden, and it is much fasciated, and I left it out of curiosity to see how it would manage to bloom. It has accomplished this feat, thanks to a week's fine weather, in a very decorative style. Seventeen pretty flowers, not in clusters, but each with a nice footstalk of about 6 to 12 inches, the lower stalks being the longest, are now showing.

around the top of the fasciated stem, and the whole is decidedly attractive.

We have but few good Roses which have originated from sports, and most of these are of recent origin. This would seem to show that the subject was now receiving increased attention, but probably the cause may be more rightly attributed to the very large number of Roses now grown and the higher cultivation they receive. The following are the most prominent among recent sports:—

THE BRIDE (T).—A most valuable American sport from Catherine Mermet. The original sometimes comes nearly white, especially if exposed to fierce sun, but such blooms are very different from The Bride, which has a distinct sulphur tinge never seen in the other. I fully expect to see The Bride shown next year if the weather be favourable, quite as large as its parent, and a most important acquisition it undoubtedly is for any purpose.

SUNSET (T).—Also from America. A sport from Perle des Jardins, is an instance of the sport coming of a darker shade than the original. Perle des Jardins is pure yellow, while Sunset is of the colour of Rêve d'Or. If this sport had improved upon the habit of its type of coming divided and confused in its strong blooms, and good on its secondary and weaker shoots, it would have been more valuable than it is, but it is a useful strong-growing sort, good in autumn, and desirable, I should think, as a pot Rose.

PRIDE OF REIGATE (H.P.).—A curious sport from Comtesse d'Oxford, the petals being striped or splashed with white, originated, I believe, in the garden of an amateur. Some people do not much admire this Rose, but it is a good shape, and certainly very distinct, no one can possibly mistake it.

LADY ALICE (H.T.).—A white or nearly white form of Lady Mary Fitzwilliam, seems hardly sufficiently distinct from the original. Mr. George Paul, who is the propagator of Lady Alice, has received with the utmost good nature a considerable amount of chaff as to our all having "Lady Alice" among our "Lady Marys," but is still of opinion, I believe, that it is a distinct sport. Let us hope that it may prove so. Lady Mary Fitzwilliam is so good a Rose that any young ladies she may introduce as debutants will, I am sure, be favourably received.

SOUVENIR D'UN PRINCE (T). is a pure white sport from Souvenir d'un Ami, which Mr. Prince showed this year for the gold medal at the Crystal Palace. This sport seems likely to be a success. The type is well known as a large pink Tea Rose of good and lasting shape, but quick to lose its colour. The blooms of the sport, as shown at the Crystal Palace, were certainly of the purest white, but the grand central spike of Souvenir d'un Ami was wanting. It was, however, shown in decidedly better form subsequently at Manchester and Darlington, and the shape of the original was recognisable. Rosarians will readily understand the value of a Niphetos with the shape and lasting qualities of Souvenir d'un Ami.

I hope some other correspondents will give us their experience in sports, as I quite think there is something to be learned in this way.—**W. R. RAILLEN.**

THE WEATHER AND GARDEN CROPS.

THE communications upon this subject have been so numerous that some must still be reserved to our next issue, and they are of too interesting a character to be reduced. Our best thanks are due to our readers for their prompt response to our request.

AYRSHIRE.

OUR rainfall in June was 2 inches, in July 3.35 inches, and up to the 13th of this present month we have had 1.90 inch. During the above time we have had very low temperature, with very little sunshine. Twice in July we registered at night 38° and 39°; from the 1st of August up to the 13th we have had only about thirty hours of sunshine. With such unfavourable weather there are very few garden crops doing well. Peas have kept healthy, but have filled their pods very irregularly. Cauliflowers have done badly, also French Beans. Early Potatoes have been a good crop, but deficient in quality. Winter crops and Celery are looking well. It would be rather difficult to mention one flowering plant that has not suffered from the ungenial weather, except the Violas; they appear to have had the weather that suits them, as they have flowered well and kept quite free from grubs. Carnations are looking well but late in flowering. Dahlias, single and double, are satisfactory. The above with some of the approved Beets and Cerastium are passable, but all Pelargoniums, except the bronze varieties, have made a poor show so far.—**DAVID MURRAY, Culzean Gardens, Maybole, Ayrshire.**

BEDFORDSHIRE.

IN June the weather was cold, dull and unsettled, when we registered 2.52 inches rain. In July rain fell on twenty-one days with very little sunshine, and at times a very low temperature. Total rainfall for the month 3.34 inches. Vegetable and fruit crops very much retarded. Apples of the Codlin type are a good average, also Blenheim Pippin, Ribston Pippin, King of the Pippins, Kerry Pippin, Court Pendu Plat, Devonshire Quarrenden, and Cellini Pippin, but Cox's Pippin is very scarce. Pears of the finer varieties are cracked, scabby, and poor. The following are the best:—Williams' Bon Chrétien, Marie Louise, Pitmaston Duchess, Beurré Clairgeau, and Louise Bonne of Jersey, but late and

small. The same remark applies to Peaches and Nectarines, but there is a good average crop. Small fruits are fairly good and plentiful. Strawberries suffered from the wet weather, but the following sorts stood the wet the best:—Amateur, Dr. Hogg, British Queen, and The Captain stood the wet better than the others, besides it was of a very bright and glossy colour. Laxton's Noble is a very showy fruit. I think it will make a good forcer, rather weak plants in 54-pots did well with me. This year Cherries are a good crop, especially Morellos. Potatoes are a good deal diseased where the ground is low and wet. The kidney type seems to have suffered the most. Most others are fairly good, but the tops show signs of disease by their scorched and shrivelled appearance. Peas have done badly, running so much to straw, and the pods not filling satisfactorily. The early type of Peas seem to have filled the best this season. Autumn-sown Onions sown on the 30th August, 1887, have done much better than those sown a fortnight earlier. French and Runner Beans have been almost at a standstill, but are now plentiful. Cauliflowers have been unusually good, and most vegetables are plentiful now. Field Cucumbers very late, not doing satisfactorily; many of the vines dying. Some Strawberries have suffered from mildew, these we shall grub up and burn.

Roses have done badly, also mildewed and spoiled by wet. Pelargoniums of the Zonal type have shown to advantage, being bright and clear. Vesuvius, Henry Jacoby, and West Brighton Gem have flowered better than most varieties. The variegated sorts, Crystal Palace Gem, Golden Superb, Flower of Spring, and Mangle-i, and Beauty of Oulton have been effective. Calceolarias Golden Gem and Aurea floribunda have stood the wet well; Ageratums badly, Alternantheras ditto, but Tuberous Begonias stand the wet well, and I think they will be much sought after for bedding purposes. Stocks and Asters stood well.—**G. R. ALLIS, Old Warden Park Gardens, Biggleswade.**

BUCKINGHAMSHIRE

WE keep no rain gauge here, consequently cannot furnish the amount of rain in inches for June and July. The rainy weather, however, commenced the second week in the first named month and continued over the end of July, during which time we experienced a very low day temperature, and day after day passed without sunshine. The night temperature was also considerably below the average for both months.

Garden crops made slow progress with few exceptions, Cauliflowers and Cabbages benefiting much, the produce fine and plentiful. Peas were late, and although the wet weather caused rampant growth the pods filled slowly, and were much affected with maggot; had the season been excessively dry we should not have expected worse. From imperfect fertilisation second crops of Broad Beans are a partial failure, in many instances the empty pods only swelling. Runner Beans are strong and now good; the earliest blooms, however, failed to set. Onions are rampant in top growth, but bulb very slowly. Celery and other vegetables generally are excellent. In fruits, Strawberries suffered the most from excessive moisture. Bush fruits are very good, Apples thin; the trees, however, have benefited much by the heavy rains.

Coniferous and other trees, with Rhododendrons, have revelled in the abundant moisture and made excellent growths. In the flower garden bedding plants generally have been much washed; Violas, however, Archie Grant, dark blue, and Mrs. Gray, white, have flowered freely. Some large Fuchsias planted out early have also flowered well through the rain. Among herbaceous plants Delphiniums, Helianthus multiflorus, Anchusa, Achillea Ptarmica fl. pl. have done well. Tricolor and bronze bedding Pelargoniums have suffered from the dull wet weather; the leafage is small, wrinkled, and stunted, and growth seems altogether crippled.—**C. HERRIN, Dropmore Gardens, Maidenhead.**

DENBIGHSHIRE.

THE weather here has been most trying for gardeners, farmers, and others, for the last two or three months rain descending nearly the whole of the time, and we had frost in July, while on August the 18th Marrows were blackened by frost, the thermometer standing at 30½°. All kitchen garden crops are good, rain suiting this garden admirably, the soil being light on a slope towards the south and on a gravelly bottom. First and second early Peas were most prolific, the varieties being Sangster's No. 1 and Telephone. Fillbasket and Hundredfold are our main crops, the latter growing to 9 or 10 feet in height, but the pods not filling satisfactorily. Veitch's Perfection is looking grand, full of vigour, and promises to do really good service. Potatoes are good, though not large, and there are no traces of disease as yet. Runner Beans are most prolific, and in fact all vegetable crops are grand. Strawberries have been a full crop, but the flavour was not good. Black Prince (for preserving) and President (for dessert) are the favourite varieties here. Raspberries were a fair crop, but many decayed through wet. Gooseberries, Black, Red, and White Currants are good both in quantity and quality. Cherries good; Pears not half a crop; Apples very irregular; Peaches and Apricots good, the former mildewed owing to so much wet and cold nights. Plums a failure, with the exception of Victorias, which are good.

With regard to bedding plants Pelargoniums are grown strong and leafy, but with little flower. Tropaeolums, Lobelias, and Calceolarias are showy. The herbaceous borders have been remarkably gay and are now. The most conspicuous are Delphiniums, Phlox, Lychnis chalcidonica, Heleniums, Hollyhocks, Bocconia, Lythrum roseum, and Fuchsia Riccartoni, all enjoying a wet and cool summer.—**J. OLDFIELD, Chirk Castle Gardens, Denbigh, North Wales.**

DERBYSHIRE.

THE rainfall for the six months ending June 30th was exceptionally low, much under average, especially so to the end of May, at which time we only registered 7.95 inches. June increased this to 10.10 inches, but as our average rainfall taking it over a series of years amounts to about 34 inches, it will be seen the above is a light record. July has in a measure compensated us by an exceptionally heavy downpour, 5.39 inches; still the season so far cannot be called a wet one measured by the quantity of rain that has fallen, but will be remembered rather for its almost total absence of sunshine and its exceedingly low temperature. May was dry and rather bright with cold east winds, which had the effect of almost entirely checking the growth of vegetation. June being dull and rather damp, although the temperature was still low, was more favourable to growth and also to the planting of bedding plants, which started away well, and have since succeeded beyond expectation; not only here, but I have observed the same at other gardens, notably the Abbey Park, Leicester, where the bedding is looking really beautiful. Violas no doubt have been the plants *par excellence* for bedding this summer; they are in grand form, and their great success this year will, I have no doubt, give an impetus to their more extended cultivation. They are so easily and so inexpensively grown.

I suppose the extreme floriferousness of forest trees, flowering shrubs, and herbaceous plants, as well as the almost unprecedented profuse display of Rhododendron we have had, must be attributed chiefly to the agency of the hot and brilliant sunshine of last year in so perfectly maturing growth, and also in a measure to the lateness of growth this spring, trees and plants thereby escaping the usually destructive spring frosts. Where lawns have been regularly mown and well kept they have never looked more perfect than this year. Here they have given much pleasure to many thousands of Americans and other foreigners who never see such beautiful lawns away from England.

In the kitchen gardens the bad weather has quite upset one's calculations as to the time of crops coming in. I am afraid if we remain much longer without warm weather (to-day it is colder than Michaelmas) that many subjects, such as French and Kidney Beans, will perish from cold before they give any yield at all. In the kitchen garden the only item of satisfaction one has is the wonderful crops on the bush fruit. I certainly never remember heavier crops of Gooseberries, Currants of all sorts, Raspberries, and Morello Cherries; but Strawberries have been poor, half the fruit has decayed on the ground.—OWEN THOMAS, *Chatsworth Gardens, Chesterfield*.

HUNTINGDONSHIRE.

THE weather and the rainfall during June and July this year has been the exact opposite to the corresponding months of last year. Those two months in 1887 were hot, with little rain, but this year there have been copious downpours with low temperatures. Fruit is late; Strawberries and many Apricots are ripening and decaying. Vegetables have been abundant, and likely to be so during the coming autumn and winter. Early Potatoes have turned out well and of very good quality; the disease, however, has now made its appearance. The showery weather has proved useful for Celery, and getting out good breadths of Brussels Sprouts, Savoy, Broccoli, and other winter Greens, which are now growing freely. Weeds also grow apace, and will get the upper hand of many gardeners where labour is limited. Kidney Beans and Vegetable Marrows are plentiful.

The rains during the last two months have been beneficial to outdoor ferneries, and especially to alpine rockery plants. Phlox setacea varieties, Alpine Auriculas, Sedums, Saxifrages, Aubrietias, double and single Primroses, and Myosotis, have all grown and flowered well, with many other dwarf plants. Border plants have benefited by the June rains. Phloxes are flowering well, and one of the best August plants to cut from has grown remarkably vigorous—viz., *Harpalum rigidum*. This plant should find a place in every garden where large quantities of cut flowers are wanted. Annuals are not much grown here, but such few that are, including Collinsia, Coreopsis, Godetia, Mignonette, Zinnias, Cornflowers, blue and yellow, Salpiglossis, Asters, Stocks, and a few others, have better growth and more flowers than last year. Beds with the usual assortment of bedding plants will certainly be better furnished with growth than last year.—A. HARDING, *Orton Hall Gardens, Hunts*.

KENT.

IN reply to your suggestion in the Journal as to recording the effects of the recent wet weather on the crops, I beg to state that here on our gravelly soil resting on chalk we have not suffered very much from the wet, although we registered 6½ inches, the heaviest rainfall for one month since October 1882, but the low temperature and absence of sun has retarded growth. Potatoes, Broad Beans, and roots generally are doing well; Peas have not filled very well; Beans, both dwarf and runners, failed to set the early flowers, but are doing better since the warmer weather; Onions have made plenty of top growth, are bulbing fairly well, but will be late harvesting; white Celery is very pithy, but red, on the other hand, is very solid. All fresh planted trees are making rapid growth, as also are Conifers, but nearly all the Pine family have been infested with the spruce gall aphid (*Chermes abietis*) not only in shrubberies, but also on single specimens. Is this pest prevalent in other parts of the country this season? Perhaps some of the numerous readers of the Journal can tell.—ROBERT FILKINS, *Gardener to G. Buchanan, Esq., Tower Fields, Keston*.

LINCOLNSHIRE.

JUNE was a variable month, but I do not register the temperature.

The total rainfall for June was 1.56 inch. Rain fell on thirteen days. July was a very cold wet month. Rain fell on twenty-one days, the greatest amount falling on the 2nd, 0.73; 4th, 0.71; 15th, 0.93; 17th, 0.52; 22nd, 0.32; 27th, 0.35; 28th, 0.48; 29th, 0.70. Total rainfall for July, 6.09 inches. Almost all kinds of vegetables are backward. Our spring Cabbages came in well and in good time (Ellam's variety excellent). Broccoli was very late, the March varieties coming in May. Cattell's Eclipse Broccoli was our latest and best this year. Turnip Early Milan, first sowing bolted for the first time this spring. Through the cold weather our early Peas did not fill before June 27th, Ring-leader variety, sown out of doors December 15th, 1887. That sown in boxes the sparrows destroyed. Early Peas were soon over. Then came the pelting rain, the second earlies not moving for eleven days. Abundance of fine Marrow Peas came in with August. I find old Ne Plus Ultra still the best all-round Pea. Cos Lettuces bolted nearly as fast as they do in a dry summer. Strawberries have been a good crop, Black Prince and President being our best croppers this year, Sir Joseph Paxton running a great deal to foliage. I tried Pauline Strawberry this year. The first flowers of Black Prince Strawberry opened May 7th; Pauline opened its first flowers May 18th. Black Prince was ripe two days before Pauline, June 24th and 26th respectively, planted side by side on south border. Pauline is a very strong grower, fruit large, but few of them. It will not drive out Black Prince for some time to come. I think. What a contrast there is between Tomatoes this year and last. At this time last year some of them had broken their stakes with their load of fruit. This year we have a few fruits about the size of pigeons' eggs, although the plants are kept to a single stem. The bottom leaves look as though they had been burnt; they first curl up, then turn brown and fall. Apples and Pears are not half of a crop. Some trees of the same variety are carrying full crops, others almost nil. Heavy crop of Red and White Currants. Gooseberries good. Raspberries a fine crop, and lasting for a long time in bearing. Asparagus very fine. Dwarf Kidney Beans came in August 8th. Runners are not gathered yet, but they are full of flower and looking well. Potatoes, a heavy crop and very large, Veitch's Ashleaf the best; the disease has shown itself. Brussels Sprouts, Cauliflower, Broccoli, Kales, &c., are looking well.

In the flower garden Begonias are far before Pelargoniums for bedding. The rain suits the Begonias. Wind is their greatest enemy; it breaks the flowers very much. Poppies are grand. Canterbury Bells have made a fine show for a long time. Sweet Williams very good, and some of them fine yet. Delphiniums fine. Phlox Drummondii very good. Petunias medium in quality. We never had Mignonette so good in the borders. Double Clarkias are splendid. Sweet Alyssum has been like a white sheet for weeks. Convolvulus is very showy in the morning. Cornflowers (*Centaurea Cyanus*) have grown taller this year, and not quite as much bloom. Godetias are beautiful. *Kaulfussia amelloides* has only done fairly well. Indian Pinks have not done well. *Mesembryanthemum tricolor* not satisfactory. Portulacas and Ice Plant complete failures. Candytuft has done well. Stocks and Asters fairly well. Gaillardias are doing well. Roses have shown plenty of bloom, but many have been spoiled.—G. PICKER, *The Gardens, Branston Hall, Lincoln*.

NORTHUMBERLAND.

DURING the month of June rain fell on thirteen days. Total during the month, 2.59 inches; mean day temperature, 56½°; mean night temperature, 44½°. In July rain fell on nineteen days. Total for the month, 4.36 inches; temperature, mean day, 54½°; mean night, 47°. Temperature for June, 1887, mean day, 63°; mean night, 48°. July, mean day, 68°; mean night, 52°.

With a few exceptions the wind has blown from the points between the east and north-west throughout the season. On the 14th of June we had a severe hailstorm, which riddled all tender leaves, and quite destroyed some of the French Beans, Scarlet Runners, Vegetable Marrows, and spoilt Tomatoes on walls, also doing great damage to the Apple crop, which had previously flowered to perfection. A quantity of Gooseberries fell, but are yielding a crop of good fruit mostly. Bush fruit generally are an average crop, Strawberries very poor, Vicomtesse Hericart de Thury excepted. In cold seasons this excels all; it never fails. A few planted last year are now yielding fine fruit. Of others Helena Gloede is a good late variety. Peas have grown well, but do not fill the pods. Potatoes are now a fine crop, but disease has made its appearance in several places. Beauty of Hebron is one of the best early, and very generally grown.

In the spring flower garden Wallflowers Belvoir Castle yellow, Veitch's dwarf dark and Covent Garden dark, were unique, sown in the beginning of May last year, transplanted in July, again planted in October. Gold-laced Polyanthus and others were splendid for spring. Of summer bedding *Tropeolum Vesuvius* surpasses all Pelargoniums for blooming. Of the latter, Henry Jacoby and John Gibbons are the best. A white Snapdragon is one of the best plants in the garden, propagated by cuttings in pots in the autumn. Yellow Calceolarias are doing well. Papaver umbrosum is good from seed sown in heat in spring. The flowers are deep red with a dark blotch, and in the distance appear floating in the air 2 feet high. It is the best flowering plant in the beds. Iceland Poppies, in three colours, are good. *Spiraea Aruncus* has been splendid.—GEORGE HARRIS, *Alnwick Castle Gardens*.

STAFFORDSHIRE.

THIS has been a very cold, dull, rainless half year. Most garden crops are late in consequence. Vegetable crops were thin and puny, but since the rains in July everything has grown enormously. They

have lost the stunted starved appearance they had before. This has been the most prolific season for grubs and insect pests I have known, both above and under ground. Cauliflowers, Savoy, and Brussels Sprouts we have planted and filled up several times, and still they go.

We have lost nearly all our *Lilium candidum* and Stocks from the same cause. Phloxes, Delphiniums, Larkspurs, Sweet Williams, Iris, Daffodils, Narcissus, and Carnations have done very well, though late. Our annuals generally have not done well. Asters, Tagetes, and Everlasting Flowers are not in bloom yet. Of bedding plants, Lobelias and Calceolarias have done well, and of Pelargoniums, such strong-growing varieties as Henry Jacoby have been satisfactory and are now flowering freely. The variegated Pelargoniums have made but little progress; Iresine has always done well till this season. *Coleus Verschaffelti* has lost all its leaves, and the stems decayed. Last year we were gathering Tomatoes out of doors by the bushel at this time. We have the same varieties in the same position (against a south warm wall) this year growing furiously, but scarcely in bloom.

Temperature and rainfall in June 1888.—Lowest night temperature, 41°; highest day temperature, 80°; lowest mean night temperature, 48°; highest mean day temperature, 66°; rainfall, 1.75 inch; highest barometer reading, 29.87; lowest barometer reading, 29.20. The rainfall for the past half year to June 30th is as follows:—January, 1.08; February, 0.44; March, 1.95; April, 1.53; May, 0.44; June, 1.75; total, 7.19. Temperature and rainfall in July 1888.—Lowest night temperature, 39°; highest day temperature, 70°; lowest mean night temperature, 51°; highest mean day temperature, 65°; rainfall, 6.06 inches; highest barometer reading, 29.72; lowest barometer reading, 29.08.—W. BENNETT, *Rangemore Gardens, Burton-on-Trent*.

THE months of June and July have been in this district remarkable for an average low temperature, and from the 20th June until the 6th August inclusive we had rain, frequently accompanied by thunder and lightning, almost every day. On the 4th July the thunderstorm was terrific, and there was also a heavy storm of hail which considerably damaged the foliage of trees and of flowering plants.

Kitchen garden crops are good, and the weather does not appear to have had any other effect than to cause them to be a few days later than usual in one or two instances—Kidney Beans for example. Considerable difficulty was experienced in gathering the Raspberry crop owing to the frequency of the thunderstorms. Where the ground has been deeply cultivated the crops have never looked back; but on ground that only had its surface "tickled" they looked cold and unhappy; but as there is very little land about here cultivated in that style the general crops are, as I have previously stated, very good.

All fruit is swelling to a good size. Apples, Plums, Peaches, and small fruits are very good crops; Pears and Damsons half crops; Apricots a failure comparatively; Walnuts are abundant; Cob Nuts scarce.

Amongst annuals the most satisfactory have been Ten-week Stocks, Phlox Drummondii, Mignonette, *Bartonia aurea*, *Nemophila* of variety, *Convolvulus minor*, *Salpiglossis*, *Godetias*, *Clarkias*, Sweet Sultan, and Yellow Sultan (*Amberboa moschata* and *odorata*), *Collinsias*, *Chrysanthemums*, *Linums*, *Campanula Lorei*, *Silene pendula compacta*, *Schizanthus* of sorts, and *Whitlavia grandiflora*; *Oenotheras* and *Eschscholtzias*, and Candytuft.

Of perennials the following have withstood the weather very well:—*Pæonies*, *Spiræas*, *Veronicas*, *Dictamnus Fraxinella*, *Campanulas*, *Pyrethrums*, *Violas*, *Chrysanthemum maximum*, *Anemone japonica* *Honorine Jobert*, *Delphiniums*, *Antirrhinums*, *Lupins*, herbaceous Phlox, *Phlox setacea*, *Hemerocallis*, *Lychnis Flos-Cuculi*, *Aquilegias*, *Iris*, *Lilium candidum*, *Lathyrus latifolius*, *Clematis flammula*, *Lysimachia thyrsiflora*, *Hesperis matronalis flore pleno*, *Bocconia cordata*, white Pinks, *Iberis*, &c.

Bedding out has not been a successful type of gardening this year, because the beds are only just looking anything like gay; but the old varieties of plants used for that purpose have held their ground this season. The best of the Pelargoniums, flowering or foliage, are Henry Jacoby (crimson), Mrs. Turner (pink), Vesuvius (scarlet), White Clipper (white), Mrs. Pollock, Bijou, Crystal Palace Gem, Flower of Spring, Mangelsii, and Duke of Edinburgh; *Lobelia Blue Stone*, and Emperor William; *Verbena* *McIndris splendens* and *V. venosa*; *Ageratum Imperial Dwarf*.

The best foliage plants, either for mixtures or carpet bedding, have been *Polemonium caeruleum variegatum*, *Pyrethrum aureum*, *Kleinia repens*, *Centaurea candidissima*, *Sedum deltoideum variegatum*, *Antennaria tomentosa*, *Iresine Lindenii*, *Salvia argentea*, *Herniaria glabra*, *Zea japonica variegata*, *Ricinus Gibsonii*, *Mesembryanthemum cordifolium variegatum* and *M. glabrum*, and *Achillea tomentosa*. *Alternantheras* are a failure.—J. UDALE, *Elford Hall Gardens, Tamworth*.

SURREY.

THE rainfall here in June amounted to 3.80 inches, and there were only six days on which rain did not fall. In July we had 4.94 inches with two fine days. The total rainfall for the year up to the end of July has been 21.54 inches, but the season has not been so bad for vegetation here as was 1879, when the rainfall in June was 5.66 with five fine days, and in July 5.48 with two fine days. The total rainfall then up to the end of July was 29 inches.

Our early Peas this year were an excellent crop, but the second crops do not fit well. Early Potatoes are much diseased, and the late varieties are affected. Cabbages, Cauliflowers, Turnips, Onions, and Carrots

are all good. Scarlet Runners, Dwarf and Broad Beans are late, and not good. Pears are a good crop; Apples and Plums partial; Strawberries, Gooseberries, Raspberries, and Currants are abundant, though wanting in flavour.

Roses have been very inferior; Hollyhocks much diseased. *Coleus*, *Alternantheras*, and other sub-tropical plants are less effective than when planted out. *Liliums*, *Dahlias*, *Carnations*, *Verbenas*, &c., seem to be enjoying the weather. There is a decided improvement all round owing to the last few days' sunshine.—EDWARD J. BAYMAN, *Holmbury Gardens, Dorking*.

THE months of June and July have been remarkable for an unusually large quantity of rain and a very low temperature. Generally this has been against the fruit crops, causing much stone fruit to fall, and affecting small fruit as regards quality. Shrubs have enjoyed the cool moist weather, and newly planted ones have done well almost without exception. Early Potatoes have yielded well, but are now showing disease. Late ones have plenty of tubers, but I fear from the present appearance of the haulm disease is likely to follow.

Amongst flowering plants hardy perennials have been decidedly the best. The following have been or are still good:—*Erigeron speciosus*, *Lilium candidum*, *Spiræas*, *Campanula persicifolia*, *Achillea Ptarmica plena*, Sweet Williams, *Violas*, *Pansies*, *Funkias*, *Echinops ruthenicus*, *Papaver orientale* (fine), *P. nudicaule*, *Centaurea montana*, *Harpalum rigidum*, *Lychnis chalcidonica*, *L. coronaria*, *Lilium umbellatum*, and *L. croceum*. *Anemone japonica* will flower later on. Many annuals are doing well. The following are some of the best:—Stocks, Asters, *Lupinus nanus*, *Clarkias*, *Godetias*, *Viscaria cardinalis*, *Collinsia bicolor*, *Nemophila insignis*, Candytufts, *Bartonia aurea*. Ordinary bedding plants have done badly. Tender foliage plants have made but little growth. Pelargoniums are beginning to flower a little now, but may be regarded as almost a failure. Our best beds are those filled with *Verbenas*, Stocks, Asters, and *Salpiglossis*. Our worst, *Zinnias* and *Portulaca*. All green vegetables have done well. Peas in particular.—E. BUTTS, *Leigham Court Gardens, Streatham Hill, S.W.*

As I did not see Surrey represented in the interesting report from the counties, I venture, though late, to supply a return from Mid-Surrey. Rainfall, 158 above sea. June, 1887, 0.71 inch; June, 1888, 3.91 inches; July, 1887, 1.01 inch; July, 1888, 5.10 inches. Wet days:—June, 1887, (2); June, 1888, (16); July, 1887, (8); July, 1888, (21). June, 1887, maximum temperature, 83°, 15th; June, 1888, maximum temperature, 82°, 25th; July, 1887, maximum temperature, 86°, 4th; July, 1888, maximum temperature, 70°, 13th, 14th, and 19th. I observe in seven instances, amid very close observing of other things, the rainfall is not given, and probably no rain gauge is kept. The cost of this now is so trifling, and the value of its record (especially to Mr. Symons) so considerable, that it is to be hoped they will be more generally adopted. The added interest to a rainy day or a thunderstorm is then very considerable.—A. C.

YORKSHIRE.

THE weather in this district during June and July has been highly detrimental to all garden crops. Peas have grown far beyond their ordinary height, with few and badly filled pods. In this respect all varieties are alike. The varieties which have done best with us are Lightning, X. L. All, Gladiator, and Prodigy. Broad Beans, Scarlet Runners, and Kidney Beans are almost a total failure. Vegetable Marrows present a stunted and starved appearance, with little prospect of many fruits coming to maturity. Potatoes have grown more to top than tubers, which are small, very late, and watery. The best are the old Ash-leaf, Veitch's Improved Ash-leaf, and Myatt's Prolific. Cauliflowers, though late, have done fairly well, Veitch's Extra Early and Walcheren are the best. Autumn and spring-sown Onions have done badly, by far the best of the former is Early White Naples; the others are not sufficiently advanced to form an opinion.

Bedding plants have made little progress. Pelargoniums in particular present a miserable appearance. Calceolarias, Lobelias, and *Violas* are doing well. Most perennials have made good growth and flowered satisfactorily. Very few annuals are grown here, and owing to the long continued cold weather they are making slow progress.

During June rain fell nineteen days, making a total of 1.98 inch. In July it rained twenty-one days, measuring 6.08 inches.—J. MCINDOE, *Hutton Hall Gardens, Guisborough*.

THE weather in this neighbourhood during the months of June and July has been very cold, sunless, and wet. We have not kept a register of the rainfall, and therefore cannot speak as to the quantity which has fallen, but can safely say that it is considerably more than that of the same two months of any of the five preceding years. Under such ungenial influences few things in the fruit garden have done what may be termed well, except all varieties of Currants, Raspberries, Gooseberries, Cherries, and Filberts, which have borne, or are bearing, very fine crops. Apples, Pears, Apricots, Plums, and Strawberries are, with very few exceptions, a failure. Peaches, Nectarines, and early Grapes have yielded a splendid crop and finished well; but late Grapes have failed to take on the bloom they have formerly done with us. Some bunches of Black Hamburg are almost green, and the flavour is not what we have usually had in them.

Cabbages, Celery, Globe Artichokes, and Turnips are the most satisfactory among vegetables, and Carrots, Beet, and Parsnips are fairly

good. Peas have produced plenty of haulm, but the pods do not fill. Onions fail to bulb. Potatoes are large and free from disease, but have few tubers to the haulm. Broad Beans which were forced and planted out have borne a heavy crop of well-filled pods, but sowings in the open are a failure. Scarlet Runners are just commencing to flower, and Dwarfs are not yet sufficiently large for use.

Flowers out of doors have been exceedingly scarce this year, especially so is the case in reference to Pelargoniums and Lobelias; however, Calceolarias and Violas have well filled their beds, and are now a mass of bloom. Early flowering Chrysanthemums and Carnations promise an abundant supply of bloom, and Pentstemons are finer than I have ever seen them. Single Pyrethrums were also finer this year than we have had them. Mignonette is poor, and most of the more tender plants, such as Heliotrope and single Dahlias, will, I fear, yield us few flowers this season. Roses we should have had in abundance, but the rain proved so inimical to their buds that most of them decayed before being fully developed.

The soil we have to deal with is a calcareous loam, resting chiefly upon gravel, and situated in a low-lying valley on the banks of the Rye.—J. RIDDELL, *The Gardens, Duncombe Park, Helmsley.*

EVENTS OF THE WEEK.—Shows still continue numerous, but the present is not a very full week in the south. On Thursday, 23rd, the Wilts Horticultural Society holds its annual Show in Salisbury, Dunkeld and Aberdeen societies having shows in the north on the same day. August 24th is fixed for the Perth Show (two days), and the members of the National Chrysanthemum Society with their friends have arranged for a trip on that day (Friday) to Baron Schröder's garden, The Dell, Egham. On Tuesday, August 28th, the Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, Westminster. A Show will be held at Sherborne on Wednesday, the 29th inst.

— **THE POTATO DISEASE AT CHISWICK.**—The attack of the murrain on the Potatoes on trial in the Royal Horticultural Society's gardens is very pronounced, in the case of some varieties virulent, and few have wholly escaped. They were examined by the Committee on Tuesday last, and an official report will be prepared for publication.

— **THE GARDENERS' ORPHAN FUND.**—Through the kindness of Mr. and Mrs. Hopwood the Gardens at Ketton Hall, Stamford, were open to the public in aid of the above on Monday, August 20th. The weather was changeable and not very encouraging, but there was a good attendance; £3 17s. was taken for admission, and 2s. 8½d. in collecting boxes, leaving a balance in favour of the fund of £2 7s. 8½d. after paying for printing and advertising.

— **THE WEATHER.**—"B. D." writes from Perthshire:—"The past week has been one of dry though coldish weather, with bright sunshine, and hopes were raised accordingly. The barometer has, however, been falling steadily for the last twenty-four hours, and to-day (20th) is again very wet." In the south the weather has been fine with occasional showers this week.

— **WE learn that MR. H. N. RIDLEY**, one of the assistants in the botanical department of the British Museum, has been appointed superintendent of the Singapore Botanic Garden.

— **ARTIFICIAL MANURES.**—Mr. H. Dunkin writes:—"I notice two slight printer's errors in my late article on 'Artificial Manures.' On page 146, the sentence that reads, 'I am a firm believer in steady and continual progress in *my* walk of life,' should be in *any* walk of life. And a little farther on, 'Trifling attention commonly known as *fads* (not facts) are better left alone.'"

— **THE MEETING OF THE BRITISH ASSOCIATION** will take place at Bath this year September 3rd to 13th. In the Biology Section, Mr. Thiselton Dyer will be President. On September 5th and 6th the annual Fruit and Flower Show will be held in the Sydney Gardens, to which all members of the Association will be admitted.

— **GARDENING APPOINTMENT.**—Mr. N. Molyneux, for the past two years head gardener to Mrs. Davies, Burton Hill, Petworth, Sussex,

has been appointed to the charge of the gardens of J. Carpenter Garnier Esq., Rooksbury Park, Wickham, Fareham, Hants. Mr. R. Gray, late gardener at Chevening, Sevenoaks, has been appointed head gardener to Mr. Spender Clay at Ford Manor, Surrey.

— **RELATIVE TO KETTON GEM MELON** certificated at Liverpool, Mr. W. Bardney writes:—"I had the pleasure of tasting Ketton Gem as well as Dickson's Exquisite, which I have long considered the best flavoured Melon in cultivation, but on this occasion at least it was excelled by the one exhibited by Mr. Divers. It was well worthy of the certificate that was awarded it. Perhaps Mr. Divers will say if it possesses a good constitution and fruits freely on the first laterals, and whether the fruit exhibited is about its size when, say, four fruits are taken from healthy plants on the first laterals."

— **THE YORK GALA.**—It will come as a surprise to many that Mr. John Wilson, for thirty years the Secretary, has resigned the secretaryship. He undertook that position at the birth of the Society, and exhibitors at the Gala know quite well how much confidence was created by the courteous attention received at Mr. Wilson's hands, for he was always a thorough business man, kind to all, and will be missed at the York Galas. Mr. Wilson is retiring altogether from the various offices of trust he held in York, and purposes living near London, and we are quite sure he will carry with him the heartiest wishes for his health and Mrs. Wilson's also, in his well earned retirement.

— **THE WAKEFIELD PAXTON SOCIETY.**—On Thursday evening last the Committee of the Paxton Society met at the "Saw Hotel" to pass the accounts in connection with the recent Window Garden Exhibition held in the Volunteers' Drill Shed. The accounts were laid before the meeting by Messrs. G. W. Fallas and T. Garnett, the two Honorary Secretaries, when it was found that in consequence of the printing and advertising charges being heavier than in previous years the expenses exceeded the subscriptions by about £5 or £6, and a hope was expressed that not only would this deficit be met, but that additional subscriptions would be secured in order that a small balance might be carried forward towards the expenses of next year's Show. A hearty vote of thanks was passed to Mr. Kingswell, who not only made the Society a present of a quantity of decorative material, but also promised a liberal subscription towards wiping off the deficiency.

— **LOMBARDY POPLARS AND LIGHTNING.**—Professor Asa Gray observed, says the *Newcastle Courant*, that the reason which lies at the bottom of the general belief, on the continent of Europe, that lightning strikes the Lombardy Poplar trees in preference to others is coming to light. Green herbage and green wood—sappy wood—are excellent conductors of electricity. A tree is shattered by lightning only when the discharge reaches the naked trunk or naked branches, which are poorer conductors. An old-fashioned Lombardy Poplar, by its height, by its complete covering of twigs and small branches, and their foliage down almost to the ground, and by its sappy wood, makes a capital lightning rod and a cheap one. To make it surer the trees should stand in moist ground or near water, for wet ground is a good conductor, and dry soil a poor one. It is recommended to plant a Lombardy Poplar near the house, and another close to the barn. If the ground is dry the nearer the well the better, except for the nuisance of the roots that will get into it.

— **IN THE REPORT OF THE CONSERVATOR OF FORESTS IN CEYLON** for 1887 it is remarked that though Sir Joseph Hooker in 1873 called attention to the rapid destruction of forests in that island, no steps were taken by the Government till 1882. In that year, as a result of a report of Mr. Vincent, of the Indian Forest Department, the Government turned its attention to the subject, and in 1855 the "Forest Ordinance" was issued. The objects of this Ordinance were, briefly, to select suitable areas of forest land and constitute them State Forests, to buy off any interests which private individuals might have in those lands, to place them under effective protection, and generally to systematise the forest conservancy. Even now the Crown forests are plundered in a wholesale fashion by organised bands of thieves, but it is hoped in a short time to put an end to this, and make the forests of Ceylon as remunerative, comparatively speaking, as those of India, where they produce a substantial revenue. Ruin has threatened the Ceylon forests, just as it threatened the forests of Jinjira, in Western India, where three-fourths of a vast forest forty miles long, and from fifteen to a hundred miles in breadth, was destroyed, and the remainder with difficulty saved.

— "W. D., *Solihull*," remarks:—"Your correspondents, "Experientia Docet," and "J. H. E.," write of the *VIOLA* with an evident admiration of the plant. Mine are in grand form still, a long border of elegans, pale lavender, with a front row of Countess of Hopetown, white, is a sight worth seeing. Some of the yellows are blooming grandly, especially Bullion and Golden Prince Improved, and Ardwell Gem, pale yellow. These are three "everybody's" varieties. Dean's True Blue is far away, the best blue, of compact habit, and very floriferous, and is not a mass of flowers here. Purples do not stand so much rain, as the flower buds damp off, and the best of all with me for standing moist weather is Unique, rich purple, with slight marking of white in the top petal. Two of Mr. Baxter's newer *Violas*, Ethel Baxter, shaded rose and plum colour, is truly a gem, so distinct and profuse, and stands bad weather well. Spotted Gem, another of Mr. Baxter's seedlings, is very lovely. Other varieties now in perfection here are Duchess of Albany, Queen of Lilacs, Bronze Queen, and a new dwarf rich black purple, Sir Joseph Terry. Many others, such as Mrs Gray, are very showy, but those I have named will suit all growers. It has taken some time to make the *Viola* popular, but the good time has come at last, and no garden in the kingdom should be without them, but once more the timely warning should be given. Plant at the proper time to be successful, but unfortunately late spring planting is often resorted to."

— THE NATIONAL CO-OPERATIVE SHOW held at the Crystal Palace on August 18th, was an interesting gathering, the variety of the exhibits, the good quality distinguishing the majority, and their surprising numbers, constituting the Show one quite out of the common. The schedule itself was a wonderful production, some fifty pages being devoted to particulars of 327 classes, and the numerous money and special prizes offered, the latter including a large proportion of books contributed by different firms and authors. The whole of the classes were not for horticultural productions. There was a section for honey, and several others for specimens of workmen's skill in various trades, medals as well as prizes being offered in these classes, and the exhibits occupied considerable space. The horticultural portion was, however, extensively represented, the greater part of both naves being filled, four rows of tables stretching for some hundreds of feet. Vegetables formed the great feature of the Show, and the competition in most of these classes was extraordinary. This was especially noticeable in section 1, for members of industrial co-operative societies, in twenty-five of which five prizes were offered in each class. Thus, for a collection of six varieties of vegetables there were thirty-five competitors; with thirty-six pods of Peas no less than seventy-six entered and showed, the classes for Beans, Carrots, Onions, Turnips, Vegetable Marrows, Celery, Potatoes, and Cabbages including from sixty to thirty exhibitors each. It was very satisfactory to observe the prevailing good quality of these exhibits, and it was only in a few cases, like Leeks and Radishes, where they were really poor, though rough coarse samples were noted in the Turnip and a few other classes. Potatoes looked well, not large, but mostly clean, even, and sound. Cut flowers were not so largely shown, and generally were not of such good quality. Plants, also, were scarcely of average cottagers' merit. Fruit was not exhibited in large quantities; a few respectable collections were shown, Apples, Currants, and Gooseberries being the chief features in other classes.

— It has been thought desirable that the FAUNA AND FLORA OF THE LESSER ANTILLES, the smaller islands of the West Indian group, should be more thoroughly investigated, and the British Association having granted £100 to initiate a research in the islands, a Committee has been formed, *Nature* states, to carry out the project, comprising Prof. Flower, Mr. Carruthers, Mr. Thiselton Dyer, Dr. Günther, Prof. Newton, Mr. Selater, Dr. Sharpe, Lieut.-Col. Feilden, and Mr. D. Morris. Prof. Flower has been elected Chairman of the Committee; Mr. Thiselton Dyer, Secretary; and Mr. Selater, Treasurer. Lieut.-Col. Feilden having accepted a Colonial appointment in Barbadoes will be in future resident at Bridge Town, where he will act as Local Secretary of the Committee, while Dr. H. A. Alford Nichols, F.L.S., C.M.Z.S., has agreed to assist in the same capacity in Dominica. In order to commence their investigations without delay, the Committee have secured the services of Mr. George A. Ramage, who was lately associated with Mr. Ridley in his expedition to the island of Fernando Noronha, and has since been collecting in Pernambuco. Mr. Ramage arrived in Dominica in March last, and has proceeded to his work with great zeal. In May, after pass-

ing five weeks at Laudat, on the right bank of the Roseau River, about 2000 feet above the sea level, he moved to St. Aroment, an estate belonging to Dr. Nicholls, just above Roseau, which he found to be a better locality for getting his plants dried. At Laudat he met with great difficulty in this matter on account of the extreme wetness of the climate. After exploring Dominica, Mr. Ramage will probably receive instructions to proceed to the other islands of the Leeward group, some of which are almost entirely unworked as regards their animal and vegetable life. Now that this important investigation has been so fairly started, it is hoped that little difficulty will be experienced in obtaining further assistance from the British Association and the Royal Society. Complete sets of all the specimens obtained will be placed in the British Museum and Kew Herbarium.

— A MEETING of the members of the Council of the ENGLISH ARBORICULTURAL SOCIETY was held recently at the Farmers' Club Rooms, Corn Exchange, Newcastle. Mr. Cadwallader J. Bates, President of the Society, occupied the chair. Mr. J. F. Robinson, Burnopfield, read a paper entitled "Remarks on the Royal Commission on Forestry, with Some Statistical Information on the Possible Future of Timber-growing in England." He said, a Select Committee having been appointed for the purpose of considering whether, by the establishment of a school of forestry or otherwise, our woodlands could be made more remunerative, the idea had occurred to him that a few remarks on the proceedings of the Commission might not be altogether without interest. If that man were a benefactor who caused two blades of grass to grow where one grew before, so a man who caused two trees to grow where one grew, or a large tree where a small one existed, was also a benefactor. The question of the growth of timber at home in place of the quantities imported from abroad, though not so important as the question of food supply, was of some importance. The danger of relying almost solely on the importation of timber from abroad was in the first place the denudation of countries of timber to provide for the growth of cereals, and in the second place, as the amount of supply decreased the demand would increase with the growth of the population. The speaker went on to recite the main points on the evidence given before the Commission. The inquiry, "If our forests are not well managed could they be improved by a more practical and scientific knowledge on the part of our foresters?" was generally answered by the witnesses in the affirmative. The evidence showed that there was much room for improvement in draining and planting, and especially in the management of small plantations. As to how the knowledge could be best obtained he agreed with the witnesses who insisted on young men receiving instructions in forests which were managed by capable men. Young men, in his view, should serve an apprenticeship of seven years, so that they might learn the habits and characteristics of their patients, and what their conditions were under different seasons. The utmost they could hope for was that, with the waste of forests elsewhere, a brighter future was in store for home forests, and that a considerable portion of the timber imported, to the amount of £16,000,000, might be raised at home. It was to be hoped that the Board of Forestry would be the means of diffusing scientific and useful information and instruction with regard to the management of woodland belonging to the State and private individuals, and that there might be no more reason for saying that we were not doing our best in utilising the productive capabilities of our possessions.

THE ROMANCE OF SEED-SOWING.

(Continued from page 153.)

ONE curious set of cases deserves a passing word while speaking of hairs. Several seeds, and also some fruits (*e.g.*, some Sages and Groundsels), are coated with short hairs containing spiral threads coiled up inside them. The hairs are usually pressed close to the seed or fruit, and kept down securely by a fibre of mucilage. The wind carries these seeds to some favourable soil, the dampness loosens the mucilage, the hairs spread out are ruptured and discharge the contained threads. These are highly elastic, and on protrusion fix the seed in the soil quite securely. Here, then, hairs serve to arrest the seeds or fruits after dispersion. The mucilage present on the seeds of Flax and Cress probably does similar duty when moistened by the damp soil.

III.—ANIMALS.—Just as animals play a large and important part in the fertilisation of flowers, so we find them taking their share in the dispersion of seeds and fruits. I cannot here give a title of the instances in which this is seen. A few must suffice. They perform their mission in different ways—some voluntarily, some unconsciously. While insects chiefly assist in fertilisation, birds and mammals are the principal agents in the work of dispersion. Fleshy fruits are attractive to

animals, because they serve as food. In these cases, therefore, the dispersion comes about by voluntary action. Three characters come into prominence when we consider this class of fruits—colour, fleshiness or juiciness, and hardness.

Colour has long been recognised as operating largely in the direction of dispersion of fruits and seeds. The æsthetic side of a bird's nature is by no means undeveloped, as we may see in many ways, and we know that birds are strongly attracted by the beautiful and varied hues of a large number of our wild berries and fruits. As we should expect, these colours are not developed until the fruit is ripe, or nearly so. It would, of course, operate injuriously, were it present at an immature stage, and Nature always takes care that during the time when a flower or a fruit needs protection it shall be so clothed or enclosed as to be inconspicuous and non-attractive. When, on the other hand, fertilisation is desired, colour and odour are laid under contribution in order to induce insects to visit the flower; when dispersion becomes necessary, colour and sweetness of taste in the fruit come into play to attract the animals of larger growth. Again, colour to be of service must, as a rule, be distinguishable at a distance. Accordingly we find that fruits develop tints that are easily set off against the background of green leaves, such as red, black, yellow, or white. Red is by far the commonest colour, varying from pink to scarlet or deep crimson. Between twenty and thirty of our native edible fruits have some shade or other of red. Among these may be named Strawberry, Raspberry, Barberry, Rose, Rowan tree, Dogwood, Honeysuckle, Holly, Arum, Asparagus, Lily of the Valley, and others. Next in frequency comes black, or hues closely approaching it—i.e., dark green or dark purple. For instance, Blackberry, Sloe, Alder, Bilberry, Elder, Plum, Ivy, Privet, and Buckthorn. Of white fruits, Mistletoe, Myrtle, and Snowberry furnish examples. I can only, for the moment, think of one actually yellow native fruit—the Sea Buckthorn of our east coasts; but we often find yellow blended with other tints on the same fruits, as in Apple and Pear, and there are some yellow seeds, as in Cornflag, which are seen when the vessels open and expose them to view. Yellow, although a showy colour, would seem to lack the power to attract, and so is for the most part absent. Not only has colour in fruits gradually developed itself in response to animal selection, but fleshiness or juiciness is traceable to the same cause. The soft, juicy pulp is both pleasant to the taste (in most cases) and good for food. Accordingly, colour having served to attract, juiciness, and in many instances sweetness steps in to satisfy. The birds have found out that the two pretty much go together, and they take care to use their knowledge. Colour is the sign-board hung out to give notice of the delicious fare to be found inside.

Different parts of the plant share in the provision of the dainty, tempting food. In Strawberry, where the tiny fruitlets are gritty and inedible, the receptacle or tip of the flower stalk enlarges by degrees into the red, juicy, sweet mass known to us all, and thus the fruits are devoured for the sake of the pulp in which they are embedded. In Raspberry and Blackberry the fruitlets themselves are juicy and sweet, and being thus better fitted to attract, we find that these plants possess fewer seeds, fewer being needed, since each one of the cluster can assert itself by means of its rich pulpy envelope. In Rose, we find fewer still; the brightly coloured hip—a development of the receptacle, hollowed out to contain the fruits (not seeds, these being inside the fruits)—presenting sufficient attraction in itself, both from its colour and composition. In Whitethorn, with only two seeds, each well protected by its own bony covering, we find perhaps the greatest attraction for birds, especially robins. Here the calyx tube forms part of the fruit. In Cherry, the outer part of the single fruit becomes juicy, as also in Plum, belonging to the same genus.

Colour and juiciness having done their part, we next find that hardness operates to prevent birds from damaging the seed. Nearly all the seeds of these fleshy fruits are protected by some tough or stony covering, such as the outside layer of the minute Strawberry fruits, or the stone of Cherry, Plum, or Hawthorn. In other cases, the outer layer of the seed itself is sufficiently tough to resist attack. In cases where the seeds themselves are edible, we often find them shut up within an envelope which is more or less bitter, as in Walnut, Beech, and the two Chestnuts. These are refused by birds, and the edible part of the seed is stored away to form food for the tiny embryo plant. Even where these edible seeds are sought for, as by squirrels, dispersion is very often effected, for many are dropped in transit, and others are forgotten and left to germinate away from the parent tree.

Birds disperse seeds in two ways. Either they carry off the fruit, and, devouring the juicy covering, drop the hard seed to the earth, or they swallow the fruits whole, as in Strawberry or Raspberry, and the indigestible seeds are dropped in the ordinary manner. We can easily see how powerful a method of dispersion is afforded by birds. Thrushes going from north to south in berry time must carry thousands of seeds to deposit them in the warmer climate. The American Currant (*Phytolacca*) was long ago introduced artificially into Bordeaux, its berries being used to colour wines. It flourishes now all over Southern France and Switzerland, and is by no means rare in the Tyrol, carried to these districts by birds.

Animals act as dispersers unconsciously, as I have already said. Many fruits possess hooked processes in the shape of curved hairs, or spines, or prickles. These become entangled in the wool or fur of sheep, cows, and other animals, and are thus effectually carried away. Of these examples are seen in wild Carrot, Bur Parsley, Hedge Parsley, Burdock, Agrimony, Avena, Enchanter's Nightshade, Hound's Tongue, Cleavers or Goose Grass (familiar to everyone who has clambered

through a hedge), and some Forget-me-nots. In Burdock, the hooks are on the scales of the involucre surrounding the flowers, so that one hook being caught carries away several fruits, which further each possess a pappus. No wonder we find Burdock everywhere. Some seeds themselves are similarly hooked—the large Stitchwort, for example, which decks nearly every hedge bank in April.

Some foreign genera, such as the Mexican *Martynia*, or Devil's Claws, possess horns 3 or 4 inches long, and *Martynia* well merits its name by the way in which it attaches itself to horses' tails and irritates the innocent proprietors. Others, like *Plumbago rosea*, are viscid, and stick to animals by this means. In *Myzodendron*, a South American parasite, whose brilliant flowers and fruits brighten the dark Patagonian forests, the fruits are provided with three long, feathery, viscid appendages, and, either carried by birds, or wafted by breezes, to some tree, they fasten themselves to a twig until germination ensues, and then grow up into plants, feeding on the juices of the tree, where they have taken lodging and board without so much as "by your leave."—H. W. S. WORSLEY BENISON, F.L.S. (in the *Journal of Microscopy*).

(To be continued.)

THE DISPUTED CUP AT BAWTRY SHOW.

As the matter of Viscountess Galway's special prize has been brought into your columns, on page 158, allow me a few words to explain what does not appear quite plain from Mr. Egglestone's letter. But first I must say that Mrs. Egglestone has returned the prize to me, and I hope will again try to win it, and be successful. It is always a double satisfaction to win such a prize two years together.

Circumstances which I need not now go into prevented the Committee holding the Show in Bawtry in 1886 or 1887, but in 1885 it was intended that the Show should be held annually. Viscount Galway was then, and is still, the President, and most of our list of patrons then are still supporting us; but in 1885 the Committee consisted of only two other gentlemen beside myself, and it was thought by several of the residents in the town that a larger Committee was desirable, and so at an early meeting this year a larger Committee was formed. I was Treasurer of the Show in 1885, but chose to take the more laborious position of Honorary Secretary on this occasion. As the claret jug was offered on condition of its being won twice, I made precisely the same rules for competition for it this year, and there was no reason for Mrs. Egglestone declining to return it for the forthcoming Show.

I did not know until seeing the Journal that the "fresh Committee" calls itself "The Bawtry Horticultural Society," though I have not the slightest objection to the title. What I object to is the implied demand by a fresh Committee for a prize they have nothing to do with. This you see is not the case, and I am glad that Mrs. Egglestone's second thoughts have proved to be the best.—W. F. ENTWISLE.

[We readily insert this letter, and are glad to find the matter is settled in what we consider the best way; but we are also bound to say our correspondent is in error in assuming that Mr. Egglestone wrote to us on the subject. We have not had a line from him nor anyone else at Firbeck.]

NOTES ON CACTUSES.

ONE of the most distinct of all the *Cereus* family is *C. grandiflorus* Maynardi, a hybrid produced many years ago from *C. speciosissimus* and the night-flowering *C. grandiflorus*, the colour of the flowers resembling the former, whilst in form they are more like the latter. In habit it partakes somewhat after the manner of both parents, but has not such a rambling habit as *C. grandiflorus*, and does not throw out aerial roots. In colour the flowers are rich red with faint tracings of orange and purple shades. In size and form it is very similar to *C. grandiflorus* but lacks its delicious perfume. It may be grown and flowered in a small compass, the plant which bore the bloom represented in the illustration (fig. 19) being in a 5-inch pot in Mr. C. M. Major's collection at Croydon. It should be said, however, that the plant in question was not in the best of health, the bloom consequently not being quite so fine either in size or colour as would be the case on a thoroughly healthy example. It should also be observed that this hybrid is not so free flowering as either of the parents, and is also more difficult to keep in a healthy state, having a habit of losing its roots during the winter months, and should consequently be watered with the greatest care, its beauty and distinctness being worthy of any extra attention that may be bestowed upon it.

During the last three or four years Mr. Major has derived much interest from a number of seedling Cactuses of the *Phyllocactus* section, and has at the present time a small batch of seedlings from *Cereus grandiflorus* Maynardi crossed with *Phyllocactus Cooperi*, a nearly white form most deliciously scented. It is hoped by this cross to obtain some new forms, and to get a sweet-scented *Cereus* Maynardi. This year blooms of the latter have been fertilised with pollen from *C. grandiflorus*, and the plant is now carrying a fine fruit. The progeny from such a cross will be looked forward to with an extra amount of interest, *Cereus* Maynardi, from its

parentage (*C. speciosissimus* and *C. grandiflorus*) being half a night bloomer already, remaining open three nights, and if shaded from bright sun two days, so that recrossing with *C. grandiflorus* may not only add another part towards making it a true night flowerer, but may have the scent transmitted to *C. Maynardi*.

Raising seedlings, although so interesting, is a somewhat slow process, as, provided they thrive well, four or five years must elapse before any flowers appear, and in many cases a more extended length of time is necessary before the plants can be induced to

that in spite of all endeavours to induce it to bloom it persistently refuses to do so. Many more varieties of *Cercus* might be noticed, and they are all more or less beautiful, and well worthy of more extended cultivation.

The *Echinocereus* should receive a passing notice; some of the varieties being very beautiful when in bloom, and when not in flower their remarkable appearance are always objects of attraction. *E. Blanckii* is very handsome, and also very free both in habit of growth as well as flowering. *E. Fendleri* is a very desirable sort to

FIG. 19.—*CEREUS GRANDIFLORUS MAYNARDI*.

bloom. The seedlings mentioned above number between 200 and 300, and during the last four seasons we have had the pleasure of seeing many of them bloom. They include several new shades of colour, and the majority of them are considered to be improvements on the old forms, having larger blooms of more substance, and are altogether a most interesting young family. Another very beautiful *Cereus* is *C. tuberosus*, a variety obtained from the Continent a few years ago. It bears a most beautiful flower of bright rosy pink colour, and is sweet-scented. It is of small cylindrical growth, and is well worthy of notice. Amongst others might be named *C. candicans*, which, although being in the collection some thirty years, is only remarkable for its slowness of growth, and

grow, and it is said that in suitable positions is quite hardy, as are some others of the *Echinocereus*. The blooms of *Echinocereus* are more lasting than most other Cactus flowers. Some of them will open every day for a week, and in some instances longer than that.

Echinocactus, known as the Hedgehog Cactus, contains some very remarkable forms of growth and very beautiful flowers of various colours, and a few should be grown in every collection of plants of this description. *Echinopses* and *Mamillarias* are closely allied to the above, and contains amongst their number some of the most curious forms of vegetable life. These all thrive in a satisfactory manner if potted in a thoroughly porous soil. The pots

should not be larger than necessary for the plants to fit in, and abundance of drainage should be provided.

CEREUS GRANDIFLORUS MAYNARDI.

"THIS magnificent hybrid is unfortunately now rather scarce, yet its beauty and distinctness entitle it to prominent attention. In 1837 Mr. H. Kenny, gardener to Viscount Maynard, Easton Lodge, Dunmow, Essex, crossed *C. speciosissimus* with pollen from *C. grandiflorus*, and, the fertilisation proving successful, seeds were obtained which produced the plant under notice. This combined the characters of the parents in a striking manner, the habit of growth and form of the flowers of *C. grandiflorus*, with the addition of the rich colour of *C. speciosissimus*, rendering it invaluable. The flowers are 9 to 11 inches in diameter, and 7 to 9 inches long, the petals more cupped than in the ordinary *C. grandiflorus*; they are rich red with a tinge of orange, and usually last for two or three days, opening every evening. At its original home, Easton Lodge, now the residence of Lord and Lady Brooke, the plant had been quite lost, until recently, by the generosity of Mr. Major of Croydon, a specimen was furnished to the gardener, Mr. H. Lister."—(*Castle's "Cactaceous Plants."*)

HORTICULTURAL SHOWS.

TAUNTON HORTICULTURAL SOCIETY'S SHOW.—AUG. 16TH.

WHEN a provincial Society expends on a single day's exhibition between £500 and £600, out of which more than £250 is allotted for prizes, and when its leading prize amounts to the handsome sum of £20, it may be fairly classed as one of the principal societies in the kingdom; and it is no wonder that it attracts to it some of our foremost men. Such is the Taunton Deane Society, which has now for years held its annual Exhibition—unlike we poor creatures in this part of England, where a society of the most moderate dimensions can hardly be kept together, and where, when a show is held, even those who have subscribed do not use their tickets. The whole countryside is astir for the Taunton Show, the neighbouring gentry make a point of coming, the town is gaily decorated with flags, villagers troop in from all around, the streets are densely crowded, the most tempting delicacies are displayed on all sides, whelks and periwinkles, sour Apples, and hard Pears stop the gangway—and, in fact, all, gentle and simple, regard it as the great day of the year. The arrangements are all excellent, a first rate band is always engaged, a grand display of fireworks takes place at night, and when the weather is favourable a financial success is assured. The last two years have been unfavourable financially, but this year there was an increase all round.

One went to Taunton this year with some misgiving. The season was a late one, and as when I left home there was not a *Gladiolus* in bloom in my garden, and other flowers were late, I felt that there must, unless the climate of the West of England were very much milder, be a falling off in this respect; while I feared that the death of Mr. Cleave of Crediton would remove one of the largest exhibitors and deprive the Show of the fine plants grown by his able gardener, Mr. Lock. The former fear was realised, as will be seen when I come to note the cut flowers; the latter happily was not so. Mr. Cleave's nephew, I believe, has succeeded him, and intends to keep up the well-known fame of his garden. As is now the case at Taunton the arrangements of the Show were all that could be desired, and everything was done to make it agreeable to all concerned—exhibitors, Judges and visitors. The Committee worked with a will, and the indefatigable Secretaries were ubiquitous.

STOVE AND GREENHOUSE PLANTS.—These form a grand feature at the Taunton Show, and when such giants in plant culture as Mr. James Cypher of Cheltenham and Mr. Lock put forth their powers we may be quite sure that a fine display will be made. There are other exhibitors, but these are the giants. In the open class Mr. Cypher came first with a magnificent twelve. In these, of course, were some well known plants, which year after year seem to increase in size and in wealth of bloom, just caught to the very day that they are required. *Kalosanthes coccinea*, one of the best bloomed plants of the plant known in our younger days as *Crassula coccinea*, *Ixora Pilgrimi*, *Erica Thompsoni*, *Clerodendron Balfourianum*, *Allamanda grandiflora*, *Statice profusa*, *Phenocoma prolifera* Barnesi, *Bougainvillea glabra*, *Erica Irbyana*, *Erica Marnockiana*, and *Erica ampullacea* Barnesi. In Mr. Cleave's collection (which in no case had names attached to them) were *Allamanda Hendersoni*, *Bougainvillea glabra*, *Stephanotis floribunda*, *Phenocoma prolifera*, *Clerodendron Balfourianum*, *Statice Horsfieldi*. In the class for six stove and greenhouse plants the same exhibitors occupied the same positions. Mr. Cypher had smaller plants than those in the twelve class, but beautifully bloomed examples of *Statice profusa*, *Allamanda nobilis*, *Bougainvillea glabra*, *Erica ferruginea superba*, *Clerodendron Balfourianum*, and *Erica æmula*. In the class for foliage plants the order was reversed, Mr. Cleave taking first with grand specimens of *Kentia australis*, *Kentia Fosteriana*, *Cycas circinalis*, *Encelphalartos villosa*, *Croton Warreni*, *Croton Williamsi*, *Croton Johannis*, and *Dasyliiron*. Mr. Cypher was second with *Kentia Canterburyana*, *Latania borbonica*, *Kentia australis*, *Cycas revoluta*, *Croton Thomsoni*, and *Croton angustifolius*. Orchids are always strongly shown at Taunton, and all Orchid growers know that it is about the dead season for

them. Mr. Cypher had a good four, consisting of *Cattleya Gaskelliana*, *Saccolabium Blumci*, *Cypripedium Stonei*, and *Cattleya crispa superba*.

In the amateurs' division Mr. W. B. Cleave swept all before him, but as his plants were not named I am unable to give them; they, however, were mostly reproductions of those exhibited in the open class. Mrs. Pearce exhibited well, and her free-flowering plants were good examples of superior cultivation. Indeed I do not think that I have ever seen a plant of *Lapageria rosea* so well done as that exhibited in this case. It was small as compared with many others I have seen exhibited, but it was one mass of flower, and the flowers were large and highly coloured. Her other plants were *Erica obbata*, *Clerodendron Balfourianum*, and *Allamanda nobilis*. John Marshall, Esq., of Belmont, was a good second, but his plants were not fully in flower; there were beautiful plants of the *Peristeria elata*, *Clerodendron Balfourianum*, *Allamanda grandiflora*, and an *Ixora*. The class which has been lately instituted for a group of plants staged for effect brought some interesting collections together, but I do not think that there was anything very suggestive in them.

Pelargoniums are always a strong feature in the Taunton Show, indeed somewhat too strong, for as far as I know it is the only place where the Golden and Silver Tricolors are assigned a place. These classes have been considerably reduced. Nosegays used to be a separate class, and Gold and Silver Tricolors had each a class, but now the Nosegays are placed with the Zonals, and the two classes of tricolors brought together, as a prelude let us hope to their disestablishment. As usual Mr. Godding carried off the first honours in the open division, while Mr. Hellard did the same in the amateurs' division. Mr. Godding's flowers comprised in the Zonal and Nosegay class, Indian Yellow, Henri Jacoby, Lizzie Early, Pioneer, White Clipper, Lord Gifford, and Bonfire; while Mr. Hellard's first prize in the amateurs' division consisted of beautifully bloomed plants of Matilda, Meteor, Lotus, Lady Sheffield, Laura Stratton, and Louisa Smith. His doubles were also fine plants; they were Mr. Buckler, Wonderful, Henri Brunner, and Marie Lemoine.

Some good plants of Lilies were exhibited by W. Newton, Esq., Barton Grange. Mr. Drummond obtained first prize for *Odontoglossum Harryanum*. Mr. Godding's Begonias were very fine, indeed it would hardly be possible to conceive better flowered plants: they were Torey Laing, orange; Beauty of St. Albans, red; The Queen, white; Wonderful, semi-double; Lady Mary, scarlet; Leviathan, red; and Floribunda. Fuchsias were hardly as good as usual; the same may be said of Cockscombs, Petunias, Balsams, &c.

CUT FLOWERS.—It was here, as might undoubtedly be expected, that the effects of the season, its backwardness and coldness, would be most evident. I have always looked forward to seeing a grand stage of Mr. Kelway's *Gladioli*, but I met a friend the day before who told me that he had been over his grounds and that on all his twenty acres there was hardly a flower to be seen. Dahlias I know, too, must be very late, and I feared other cut flowers would be dirty and indifferent in character, and so it was. There was, with the exception of Mr. Kelway's stand, not a *Gladiolus* in the Show worth looking at, while, instead of the long bank which Mr. Kelway is in the habit of putting up, there was but a small stand of twenty-four, but, of course, these were worth lingering over. Amongst them were three, to which certificates were awarded—viz., Orbit, a brilliant scarlet flower with white centre; Faust, surely wrongly named, a delicate soft pink; and Regalia, a crimson pink with white centre; these were all fine flowers and formed a handsome spike, the first named being a particularly brilliant flower. Certificates were also awarded to Messrs. R. Veitch & Son for some yellow ground Carnations exhibited in their fine group—Dorothy, Annie Chambers, Annie Douglas, and Alina. Dahlias were very inferior, both in quality and quantity. One missed the fine collection of Dahlia blooms from Keynes, Williams and Co. of Salisbury. Asters were exhibited in better condition than I had anticipated, but I was somewhat disappointed that Roses were not more largely shown, for in the open division there were but two exhibitors, Dr. Budd and Messrs. Cooling & Son, and in the amateurs' division Dr. Budd and Mr. Hobbs of Bristol. One missed Messrs. Keynes, Mattock, and others who are wont to exhibit here, and I suppose that the very unpleasant season must have been the cause of their non-appearance. Dr. Budd fully sustained his reputation as a first-rate rosarian, and amongst his blooms were to be found fine blossoms of Duchess of Bedford, François Michelin, Ulrich Brunner, Alfred Dumesnil, Marquise de Castellane, Jean Ducher, Comtesse d'Oxford, Alfred Colomb, Mons. Noman, Jean Liabaud, Alba rosea, Abel Carriere, Madame Charles Crapelet, Hon. Edith Gifford, Madame Gabriel Luizet, Marie Verdier, Innocente Pirola, Comtesse de Nadaillac, Louis Corbie, Dingé Conard, Comtesse de Srenye, Rubens, Souvenir d'Elise, Baroness Rothschild. Messrs. Cooling had also fine stands, in which were good examples of A. K. Williams, Alfred Colomb, Baroness Rothschild, and many other well known varieties. There were some excellent boxes of cut blooms of Pelargoniums exhibited by Mr. Collard and Mr. Wellard, and as these were grown under glass they were not influenced by the weather as the other cut flowers were, nor would it do to pass by without notice the beautiful box of cut blooms of stove and greenhouse plants exhibited by John Marshall, Esq., of Belmont, they were very fresh and brilliant in colour.

TABLE DECORATIONS.—These have always been much encouraged at Taunton, and on this occasion four tables arranged for dinner were set up. The judging of these is a most difficult matter, and if not a thorny subject is a very "pinny" one, for shoals of ladies are quite ready to do anything to the Judges, whose decisions are always the subject of the most contemptuous remarks. When I have to judge these I

generally "make tracks" before the ladies come in. It is cowardly, no doubt; but then, I am of that very sensitive nature that a lady's adverse criticism crushes me. However, it is no laughing matter, and there is this knotty question to be decided—The fashions in these things change, and are we to decide as to which is the best table according to the prevailing fashion, or the best according to our ideas of what the true canons of taste are? Now, on this occasion there were tables arranged according to the present fashion, with satin down the centre, and flowers arranged in low receptacles on it; and others, like that of Mr. Cleave, arranged with the three upright stands in the centre of the table, most elegantly and gracefully arranged. I have no doubt the lady who put up the former was "down upon" the Judges pretty hard, and it is a moot point. If judgment is to be according to fashion this no doubt would be correct; but I rather incline to the view that we have nothing to do with fashion, but with what we consider to be good taste; although I am perfectly aware no judgment will alter fashion, and that you might as well expect ladies nowadays to wear pork pies instead of the lofty towers they place upon their heads now, as to alter what they have graciously pleased to decree shall be the fashion. There were some very handsome bouquets exhibited, and although one might very well take exception to their size, yet here again fashion carries the day, and perhaps had there been any moderate sized ones exhibited they would have been placed before these huge and unwieldy things. Some pretty stands of wild flowers were also shown.

I can say nothing as to the fruit and vegetables, for I had not even time to go into the tents where they were exhibited; but I have no doubt other correspondents will supply this. I have attempted to give a general view of the floral departments, but to have done this as it deserved would have required a much larger space than you can afford to give.—D., Deal.

FRUIT.—A better collection was staged than anticipated, the only appreciable falling off being in the hardy fruit classes. Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, was first for a collection of ten dishes, having good stands of fairly well coloured Madresfield Court and Buckland Sweetwater Grapes, a fine Smooth Cayenne Pine Apple, Searlet Invincible Melon, Exquisite Peaches, Pine Apple Nectarines, Black Tartarian Cherries, Negro Largo Figs, Moorpark Apricots, and Jargonelle Pears, all of good size and well ripened. Mr. Iggulden, gardener to the Earl of Cork, staged a collection similar to that he had at Weston-super-Mare two days previously, and it was questionable if he received justice at the hands of the Judges. Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, was third, the Grapes in this collection being very fine. Mr. W. Daffurn, gardener to Donald Cox, Esq., was placed first for four dishes of fruit, these consisting of fairly good Madresfield Court Grapes, Blenheim Orange Melon, Noblesse Peaches, Elruge Nectarine. Mr. Pratt was second, and ought to have been first. The third prize went to Mr. Crossman, gardener to J. Brutton, Esq., for a creditable lot, and another very pretty lot was left out in an unaccountable manner. The class for Black Hamburgh Grapes was a fairly good one. Mr. Pratt was well first with bunches and berries of good size and colour. Mr. Iggulden was second with large and rather overripe bunches, and Mr. G. Cooper, gardener to C. L. Collard, Esq., third with fine compact bunches. In the class for Muscat of Alexandria Mr. Ward was first, his bunches being well coloured but stale. Mr. Pratt was second with much finer bunches, which, however, were not well coloured, and Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., a good third. The first prize in the class for any variety of black Grapes, Mr. W. Daffurn was placed first for Madresfield Court, large but not well finished, Mr. Ward being second with Gros Maroc beautifully finished, the third prize going to Mr. J. H. Virgo for loose examples of Madresfield Court. The strongest competition was with any white variety of Grapes, the first prize going to Mr. J. Webber, gardener G. F. Zuttrell, Esq., who had large but rather green Buckland Sweetwater. The second prize was awarded to Mr. J. Lloyd for perfect Foster's Seedling, which ought certainly to have been first. Mr. Cooper was third with fine but scarcely ripe bunches of Foster's Seedling. Melons were not largely shown, but the quality of the winning fruit was decidedly good. Mr. Crossman was first with a fine fruit, Hero of Lockinge, Mr. Ward second with the same variety, and Mr. Iggulden third with Golden Gem scarcely ripe. Mr. Iggulden was placed first for a highly coloured dish of Sea Eagle Peaches, Mr. Daffurn being second with a handsome dish of Grosse Mignonne. The last named was first with a handsome dish of Elruge Nectarine, and Mr. Crossman second with the same variety. The best Apricots were staged by Mr. R. Huxtable, gardener to F. W. Newton, Esq.; Mr. E. Bradbeer being a good second. Mr. C. Lucas had the finest dish of Pears, staging good Jargonelle, and Mr. Daffurn was second with the same variety. Plums were fairly plentiful and good, and Cherries were very fine. Apples were plentiful, the culinary varieties being very fine. Other hardy fruits were less numerous, but the quality was good.

A remarkably fine number of vegetables were shown both by professional gardeners and cottagers. Messrs. Webb & Sons offered prizes for six varieties, and with these Mr. G. Garraway was first, Stourbridge Marrow Peas being very good. Mr. H. Moore was a good second, and Mr. T. Tilley, gardener, to Mrs. Cotgrave, third. In another similar class the prizes were provided by Messrs. Sutton & Sons, and in this instance Mr. T. Tilley was first, Sulham Prize Celery, Sutton's Seedling Potato being especially good in this collection. Mr. G. Rieks was second and Mr. H. Moore third. The competition in both classes was keen. The Society offered good prizes for ten varieties of vegetables, and with

these Mr. T. Evry, Bath, was first, among these being very fine Webb's Chancellor Peas, Trophy Tomatoes, Duke of Albany Peas, Wright's Grove White Celery, and Snowball Turnips. Mr. J. Webber was a very good second, Sutton's Seedling Potato, Telephone Peas, Haekwood Park Potatoes being very good in this collection. Potatoes as usual were very plentiful and good. The best six varieties were shown by Mr. H. W. Ward, who had very handsome dishes of Schoolmaster, International Kidney, Prizetaker, Blanchard, Woodstock Kidney, and Vicar of Laleham. Mr. J. H. Virgo was second. Mr. Webber was first for a round variety, and Mr. Ward second, both having Reading Russet good. In the class for kidney varieties Mr. Webber was first for a grand dish of Sutton's Seedling, and Mr. Virgo second with the same variety. A variety of other vegetables were also largely and well shown in the various classes provided for them. Cucumbers as a rule were too large. Mr. Webber was first with a fine brace of Carter's Model and Mr. Crossman second. Ten good dishes of Tomatoes were shown, Mr. W. Iggulden taking the first prize for Carter's Perfection, large and handsome, the second prize going to Mr. J. Lloyd for Haekwood Park in good condition. Mr. W. J. Durk, gardener to H. J. Penny, Esq., was first for a basket of salad, Mr. Rieks being second. The last-named was first for a collection of Gourds.

MAIDENHEAD.

IN somewhat gloomy but fortunately dry weather the Maidenhead Horticultural Society held its annual Show on Thursday last in the grounds of Ray Lodge, kindly lent for the occasion. It proved a decided success. Specimen plants, groups for effect, and also fruit and vegetables were well shown. Several groups of plants and extensive collections of cut flowers contributed, not for competition, helped in a large measure to make a most successful exhibition. Specimen plants.—For six stove and greenhouse plants, half to be in flower, three exhibitors entered, the first prize going to Mr. J. F. Mould, nurseryman, Pewsey, Wilts; second to Mr. Aitken, gardener to Mrs. Meeking, Richings Park, Slough; and third Mr. Thomas Manley, gardener to F. H. Holmes, Esq., West Hill House, Henley. Mr. Mould's best plants were *Kentia Fosteriana*, *Cycas revoluta*, and *Allamanda Hendersonii*, while Mr. Aitken had good *Kentia australis*, *Croton Johannis*, and *Rondeletia speciosa*. Mr. T. Loekie, gardener to G. O. Fitzgerald, Esq., Oakley Court, Windsor, had the best eighteen fine-foliage plants in 8-inch pots, excellent half specimens. Conspicuous were *Crotons Weismanni* and *Queen Victoria*, *Kentia Fosteriana*, *Bambusa variegata*, and *Asparagus plumosus*. Mr. Griffiths, gardener to Col. Harvey, Springfield, Taplow, was second with smaller plants. For six stove and greenhouse Ferns Mr. Aitken was first with some good plants, especially so were *Gymnogramma peruvianum argyrophyllum*, *Pteris scaberula*, and *Goniophlebium subauriculatum*; second Mr. T. Manley; third Mr. Hughes, gardener to H. F. de Paravieini, Esq., Heathfield, Bracknell. Several exhibitors competed in the class for a single specimen stove or greenhouse plant in flower, and here Mr. J. Hanch, gardener to J. P. Weatherby, Esq., Melworth Lodge, Cookham, was first with a large and well flowered *Eucharis amazonica*, Mr. Aitken second, and Mr. Griffiths third. For a single foliage plant Mr. Aitken was first with a large *Croton Queen Victoria*, second Mr. Loekie, third Mr. Hughes. Mr. Loekie was first for six table plants, consisting of *Pandanus Veitehi*, *Dracena superba*, *Coeos Weddelliana*, *Geonoma gracilis*, *Croton Laingi*, and *Aralia Veitehi*, a very good selection. Second Mr. Waite, gardener to Col. the Hon. W. Talbot, Glenhurst, Esher. Third Mr. Aitken. Six *Fuchsias* were shown in fair condition by Mr. Hopkins, gardener to J. W. Burrows, Esq., The Elms, Cookham. The other exhibits were very poor.

Mr. Goodman, gardener to C. Hammersley, Esq., Abney House, Bourne End, contributed the best six Tuberous Begonias, large, well-bloomed plants of old varieties. Mr. Hopkins a good second. For six Zonal Pelargoniums Mr. Aitken was first with some fine plants, 3 to 4 feet in diameter, and well flowered, *Queen of the Whites*, Dr. Orton, and F. V. Raspail among the best. Coleuses were staged in quantity, the best plants coming from Mr. Paxton, gardener to the Hon. C. S. Irby, Hitcham Grange, Taplow; second, Mr. Hopkins; third, Mr. G. Squeleh, Boyne Hill.

Groups for effect formed one of the leading features of the Show, and were much admired, especially so the first prize group contributed by Mr. Aitken. The plants were required to fill a space of 12 feet by 10 feet, on low staging. Mr. Aitken had for his central plant a handsome *Coeos Weddelliana*, the groundwork composed of Maidenhair Ferns with a mixture of nice *Gloxinias*. The groundwork was raised in the centre, covering the *Coeos* pot. Springing out of the groundwork he had highly coloured *Crotons* and *Dracaenas*, *Tuberoses*, *Gladiolus*, *Francoa ramosa*, *Eulalia latifolia* var., *Hyacinthus candicans*, &c., and well finished at the sides with drooping *Panicleum*, Ferns, and *Caladium argyrites*, the whole forming a beautiful and well-arranged group. Mr. G. Hiatt, florist, Slough, was second, also with well-arranged plants, but wanting in finish at the sides. Third, Mr. R. Owen, nurseryman, Castle Hill, Maidenhead. The smaller groups, 6 feet by 5 feet, were poor, and too much packed by all the exhibitors. Mr. Hughes was first, Mr. Griffiths second, Mr. Mould third.

Cut flowers were staged in quantity, Mr. Walker, nurseryman, Thame, had the best twelve Roses, all very good. Mr. Hughes second. Mr. Walker was also first for twelve Dahlias and the same number of Asters. Mr. Broughton obtained a first prize for a bridal bouquet, Mr. Hiatt being second. In a ladies' competition for three vases of flowers arranged for the table, Mrs. Spencer was first with a very pretty arrangement, and Mrs. King second.

Fruit.—In the leading class, that for six dishes, Mr. Aitken was first

with a Queen Pine, good Black Hamburgh Grapes, rather green Muscats, Pine Apple Nectarines and Royal George Peaches, and a small Melon. Mr. Goodman was a very good second with much better dishes of Peaches and Nectarines, a grand dish of Kirke's Plum, Victory of Bristol Melon, and fair black and white Grapes. For four dishes, Pines excluded, Mr. D. Paxton, gardener to the Hon. C. S. Irby, Hitcham Grange, Taplow was first, having in his collection very good Foster's Seedling Grapes; second, Mr. W. Woolford, gardener to J. Mackmeiken, Esq., Little Missenden Abbey, and for four varieties grown in the open air Mr. Aitken first and Mr. Goodman second, Mr. Hughes third. Three bunches of Black Hamburgs were shown in fine condition by Mr. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, who was first, Mr. Hopkins second, and Mr. Goodman third. Mr. Osman was also first for three bunches black, any other variety, second Mr. Waite, third Mr. Goodman, all showing Alicante. White Muscats were poorly shown, but in the succeeding class for any other variety the competition was good. Mr. Paxton had large and well-coloured Foster's Seedling, and was first, Mr. Osman second with the same variety, Mr. Hughes third. Mr. Goodman was first both for six Peaches and the same number of Nectarines, and Mr. Waite second. Apples and small fruits were well shown by several exhibitors.

Vegetables made an imposing display, being staged in large quantities; the quality throughout was also good. Messrs. Sutton & Sons, Reading, offered prizes for six varieties, for which there were eight competitors, all showing well. Mr. Waite succeeded in obtaining first place, having extra fine Sutton's Perfection Tomato, New Intermediate Carrots, and Satisfaction Potatoes. Mr. Lockie was a close second, Mr. Manley third, Mr. Woolford fourth. Mr. Waite also won the first prize for six varieties offered by Messrs. Webb & Sons, followed by Messrs. Lockie and Woolford. In a strong competition Mr. Lockie was first for six dishes of Potatoes, having Sutton's Seedling, Satisfaction, Prizetaker, Snowdrop, Reading Ruby, and Reading Russet. Mr. Hughes was a good second, Mr. Woolford third. Many prizes were offered for single dishes of vegetables, in which the competition was extremely keen and the produce excellent.

Miscellaneous contributions, not for competition, helped to make up a most successful Show. Messrs. Sutton & Sons sent a large collection of cut flowers, chiefly of annuals grown from their selected seed stocks. They also staged a group of Gloxinias, of a beautiful strain and distinct from many varieties in commerce. It is called their "Netted Strain." Those shown were heavily veined with white on a bright red ground. A first class certificate was awarded. Messrs. Veitch & Sons contributed eight boxes of excellent Roses from their Langley seed grounds. Finely represented were *Senateur Vaisse*, *Merveille de Lyon*, *Marquise de Castellane*, *Heinrich Schultheis*, *A. K. Williams*, *La France*, *Eugène Furst*, *Fisher Holmes*, *Baroness Rothschild*, *Madame Victor Verdier*, and *Grace Darling*. From Mr. Owen came a group of fine Tuberous Begonias, single and double, also two boxes of cut blooms, and bunches of Dahlias in variety, *Pyrethrums*, *Chrysanthemums*, &c. Mr. E. F. Such sent a collection of cut flowers in variety, Mr. Broughton a group of Lilliums and Tuberose in a setting of Maidenhair Ferns, and Mr. Burdett a group of Begonias and Zonal Pelargoniums. Mr. W. Clark, horticultural builder, Reading, exhibited specimens of his patent glazing, which the Judges highly commended.

A word of praise is due to Mr. O. King, the courteous Secretary, whose arrangements throughout were excellent.—C. H.

WESTON-SUPER-MARE.—AUGUST 14TH.

FAVoured with lovely weather, and a grand all-round display of plants, cut flowers, fruit, and vegetables, a great success was almost unavoidable. Never before has everything gone so smoothly at this popular Show, and the arrangements made by Mr. Frank F. Perrett, the excellent Secretary, assisted by a hardworking Committee, gave the greatest satisfaction to the exhibitors generally.

There were four entries in the principal class, that for twelve plants, eight to be in flower, the prizes for which were fifteen guineas, ten guineas, five guineas, and three guineas, and in this Mr. J. Cypher, Cheltenham, was well first; Mr. George Lock, gardener to W. B. Cleeve, Esq., Crediton, second; Mr. Wills, gardener to Mrs. Pearce, Southampton, third; and Mr. W. Brooks, Weston-super-Mare, fourth. Mr. Cypher had very fine specimens of *Ericas Marnockiana*, *ampullacea*, *Barnesi*, *Thompsoni*, and *Irbyana*, an immense *Phœnocomia prolifera* *Barnesi*, a good *Bougainvillea glabra*, *Ixoras Reginae* and *Pilgrimi*, *Kentias Fosteriana* and *australis*, *Cycas revoluta*, and *Cordyline indivisa*, all in capital condition. Among Mr. Lock's plants were fine and beautifully coloured *Crotons Johannis* and *Williamsi*, an immense *Latania borbonica*, a good *Cycas circinnalis*, and well-flowered specimens of *Allamanda Hendersoni*, *Erica Fairrieana*, *Clerodendron Balfourianum*, and *Erica Eweriana*. Mr. Wills had a small but beautifully flowered *Lapageria rosea* and a good *Erica obbata purpurea*. Mr. Brooks, the local grower, also staged a few creditable plants. The best six flowering plants were staged by Mr. Cypher, and consisted of *Bougainvillea glabra*, *Statice profusa*, *Erica æmula*, *Clerodendron Balfourianum*, *Allamanda nobilis*, *Kalanthes coccinea*, all in capital condition. Mr. Wills was second, his best being *Eucharis amazonica*. Mr. Lock was well first with four flowering plants, these consisting of *Allamanda Hendersoni*, *Clerodendron Balfourianum*, *Stephanotis floribunda*, and *Erica Lindleyana*, all fresh and good. Mr. C. Holland, gardener to W. Ash, Esq., Weston-super-Mare, was a creditable second, and Mr. W. Brooks third. Three competed in the class for a greenhouse flowering plant, Mr. Cypher being well first with a fine *Erica ferruginea superba*, and Mr. Lock second.

Mr. Cypher was again first with a stove flowering plant, having a beautiful specimen of *Allamanda grandiflora*; Mr. Lock was a good second with *Clerodendron Balfourianum*.

In the class for six fine-foliaged plants Mr. Lock was well first, his group including wonderfully fine and well coloured *Crotons Princess of Wales* and *Warreni*, a good *Dasyllirion acrotrichum*, *Kentias Fosteriana* and *Belmoreana*, and *Cycas circinnalis* large and healthy. Mr. Cypher was a good second, and Mr. W. C. Drummond, Bath, third. The best four fine-foliaged plants were staged by Mr. Wills, Mr. James Lloyd, gardener to Vincent Stuckey, Esq., Langport, being a very creditable second, and Mr. W. Brooks third. Mr. Lock was well first for a single specimen, having a beautifully coloured *Croton Chelsoni*. Mr. Wills was second. The first prize for six *Adiantums* was awarded to Mr. C. Holland, *A. farleyense* and *A. cardioclæna* being the most noteworthy among the collection. Mr. Wills was second, and Mr. W. Pain, Weston-super-Mare, third. Mr. Lock had the best four *Adiantums*; Mr. W. Brown, gardener to the Rev. W. W. Aldridge, Weston-super-Mare, being second, and Mr. H. Marshall, gardener to R. Cox, Esq., Weston-super-Mare, third. The prizewinners with hardy Ferns were Messrs. G. Lock, W. Brooks, and Mr. E. Wills and Mr. C. Holland, while the prizes for Lycopods were awarded to Messrs. E. Wills and G. Lock in the order named in each instance. Mr. J. Cypher was easily first for four Orchids, these consisting of *Cattleya Gaskelliana*, *Cattleya crispa*, *Saccolabium Blumei*, and *Cypripedium Stonei*, all fresh and well flowered. Mr. Wills was second, and Mr. W. Brooks third. The first prize for a new and rare plant was awarded to Mr. Cypher, who had *Odontoglossum Harryanum* carrying a spike of nine large and very beautiful flowers; Mr. Lock was second with *Alocasia Sanderiana*.

All the foregoing were staged in one large tent, a variety of Ferns and commoner plants, as well as a grand display of Roses and other cut flowers, being prettily arranged in a second roomy structure. Mr. Lock had eight grand Ferns, including *Cibotium princeps*, *Marattia Cooperi*, *Davallia polyantha*, *Gleichenia spelunce*, and *Nephrolepis davallioides furcans*, and was awarded the first prize. Mr. W. Lewis, gardener to J. E. Cole, Esq., was a very creditable second, and Mr. W. Brooks a good third. With Gloxinias Mr. C. Holland was well first, and Mr. W. Lewis second. Mr. W. Brooks had a first for six well flowered trained Clematises, and Mr. W. Lewis was well first for four Achimenes. Mr. W. Lewis was also first for Cockscombs, and Mr. C. Holland second; while the first for six Lilliums was well won by Mr. W. Brooks, the second prize going to H. B. Farrington, Esq. Mr. C. Holland was first for a light Fuchsia, and Mr. Brooks second, these positions being reversed in the class for a dark variety. Mr. W. Brown was first for four double Tuberous Begonias, and Mr. G. Adams second. The best four single Begonias were staged by Mr. C. Holland, and with six varieties Mr. G. Adams was first. Mr. Holland staged six very pretty Coleuses, and was first, the second prize going to Mr. W. Brooks. The last named was first for Petunias, Mr. J. Dyer for tricolor Pelargoniums, Mr. Lewis for Balsams, and Mr. Sydney Birslee for Zonal Pelargoniums, the competition being keen in each instance.

A grand lot of Roses were shown, several noted growers being counted out. For twenty-four triplets Messrs. Perkins & Sons were well first, having *Duke of Teck*, *A. K. Williams*, *Countess of Rosebery*, *A. Colomb*, *Marie Baumann*, *Louis Van Houtte*, *Henry W. Eaton* (a doubtful sport from *Senateur Vaisse*), *Charles Lefebvre*, *Devienne Lamé*, *Mlle. Marie Rady*, *Horace Vernet*, *Maréchal Niel*, and *Eclair*, very fine and fresh. Dr. S. P. Budd, Bath, was a fairly good second, *Marie Baumann*, *A. K. Williams*, *Souvenir d'Elise Verdier*, and *Marie Van Houtte* being among his best. Messrs. G. Cooling & Sons, Bath, followed very closely, their best being *Marshal P. Wilder*, *Duc de Rohan*, *A. Colomb*, and *Lady Sheffield*. The first prize for twelve Roses was well won by Messrs. Heath & Son, Cheltenham, their best being *Countess of Rosebery*, *Niphetos*, *Annie Wood*, *La France*, *Duke of Edinburgh*. Mr. T. Hobbs, Bristol, was second, and Mr. W. Smith, Bristol, third. Dr. Budd was well first for twelve Teas, among these being good *Madame Lambard*, *Madame de Watteville*, *Comtesse de Nadailac*, *The Bride*, *Anna Ollivier*, *Marie Van Houtte*, and *C. Mermet*. Messrs. Cooling and Sons were second, and Mr. J. Mattock third, both having several good blooms, and others past their best. Messrs. Heath & Sons were deservedly awarded the first prize for twenty-four Dahlias; among these the best were *Buttercup*, *Prince Bismarck*, *J. Cocker*, *Statesman*, *Fanny Sturt*, *Mrs. Gladstone*, *John Wyatt*, *Harrison Weir*. Mr. S. Hobbs was first for twelve Dahlias, and Mr. W. Brooks second. Single varieties were fairly good, but flagged badly. Mr. A. A. Walters, Bath, was first, and Mr. T. Evry second. Messrs. G. Cooling & Sons were well first for cut Verbenas, and Mr. Walters second. Messrs. Cooling & Sons were first for quilled Asters, and Mr. W. S. Jones, Bath, second; and with French Asters Mr. G. Garraway was first, and Mr. W. S. Jones second. Mr. R. Richards was well first for twelve varieties of choice cut flowers, and Mr. C. Holland second. Mr. W. Brooks was first for Zonal Pelargoniums, and Messrs. Cooling & Son second. Mr. J. Ashwell, gardener to J. B. Braine, Esq., was first for a vase of flowers and fruit, Mr. Brooks second, and Mr. F. Edwards third. Several very fine bouquets were staged, Messrs. Perkins & Sons, Coventry, being first, and Mr. W. Garraway, Clifton, second, both having very tastefully formed bouquets, in which Orchids largely predominated.

On the whole excellent samples of fruit was staged, and the vegetables generally were remarkably good. The best collection of eight dishes of fruit was shown by Mr. W. Iggulden, gardener to the Earl of Cork, who had a good Queen Pine Apple, Black Hamburgh and Muscat of Alexandria Grapes, the latter not well coloured, a handsome Golden

Gem Melon, very fine Sea Eagle Peaches, Florence Cherries, Brown Ischia Figs, and Lord Napier Nectarine. The second prize was awarded to Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, who had good Alicante and Muscat of Alexandria Grapes, and very fine Figs, Nectarines, and Peaches. The third prize was awarded to Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, his Muscats and Hamburgh Grapes being very fine. With four dishes Mr. A. Crossman, gardener to J. Brutton, Esq., Yeovil, who had fairly good Muscat of Alexandria Grapes, a good Hero of Lockinge Melon, handsome Pine Apple, Nectarines, and Bellegarde Peaches. The second prize was awarded to Mr. W. Daffurn, gardener to D. Cox, Esq., Elruge Nectarines being very pretty, while Mr. J. Lloyd was third, a faulty Melon spoiling his chance for a better position. Mr. Lock was deservedly first for a Pine Apple, staging a very fine Smooth Cayenne. Mr. Pratt was well first for Black Hamburgh Grapes, having fine well finished bunches. Mr. W. Carpenter, gardener to A. Cole, Esq., was second, and Mr. J. Loosemore third. In the class for any other black variety Mr. Nash was first with beautifully clean and well finished Alicante. Mr. J. Lloyd being second with good Madresfield Court, and Mr. Daffurn third with the same variety. Mr. Pratt was awarded the first prize for Muscat of Alexandria, large in bunch and berry, but not ripe. Mr. W. Coates, gardener to Mrs. Miller, was a good second, and Mr. J. Lloyd third. The competition with any other white Grapes was good. Mr. J. Attwell, gardener to J. P. Brann, Esq., was first with well coloured Buckland Sweetwater, Mr. Iggulden being second with rather overripe Foster's Seedling, and Mr. F. Edwards third with the same variety. In the class for green-fleshed Melons Mr. Iggulden was first with a very fine fruit of Golden Gem, the second prize going to Mr. Pratt for a good fruit of Longleat Perfection. Mr. Iggulden was also first for a scarlet-fleshed variety, having Blenheim Orange in good condition; Mr. Holland being second with Sutton's Scarlet Invincible. Peaches were not largely shown. Mr. Daffurn was first for very fine Grosse Mignonne, and Mr. Iggulden second with the same variety. Mr. Daffurn was also first for Nectarines with very handsome Elruge, Mr. Iggulden being second with Pine Apple. Mr. Iggulden was first for Figs and second for Apricots, the first prize in the latter class going to Mr. T. Pople. Some fine Cherries were shown. Mr. Nash was first and Mr. Iggulden second. Nine good dishes of Tomatoes were staged, Mr. Iggulden being well first with very large fruits of Carter's Perfection.

The best eight dishes of vegetables were staged by Mr. Evry, Bathampton, these including good Duke of Albany Potatoes, Wright's Grove White Celery, Telegraph Cucumbers, Carter's Champion Runner Beans, Dwarf Erfurt Cauliflowers, Trophy Tomatoes, and Duke of Albany Peas. Mr. G. Tilley, gardener to Colonel Cotgrave, was a good second, and Mr. G. Garraway third. Mr. J. Lloyd was first for a pretty brace of Tender and True Cucumbers, and Mr. Garraway second. Potatoes, Peas, Onions, and other vegetables were also well shown in the various classes provided for them. Special prizes were offered for six varieties of vegetables by the Messrs. Sutton & Sons, Reading, and also by Messrs. Webb and Sons. For the former Mr. T. W. Gedge was first, and Mrs. Cotgrave second. For Messrs. Webb's prizes capital vegetables were also shown. Mr. G. Garraway was first, Mr. T. W. Gedge second, and Mrs. Cotgrave third.

WELLS.—AUGUST 15TH.

It is some years since a summer show has been held in Wells, and it is hoped the great success attending its resuscitation will lead to a second attempt being made. The Show was held in the historical and highly interesting grounds connected with Wells Palace, than which a better place could not well be found. Thanks to the active interest taken in the Exhibition by the Lord Bishop of Bath and Wells the attendance of fashionable visitors in the early part of the day was very good, while in the evening crowds of sightseers thronged the tents and grounds. Mr. Richard Harris was the Honorary Secretary, a staff of gentlemen rendering him good assistance on the Committee.

In the plant classes the best prizes were offered for a group of stove and greenhouse plants, the major portion to be in bloom. The first prize was well won by Mr. T. Wilkinson, gardener to C. C. Tudway, Esq., who had a very pretty arrangement in which a lot of well grown *Campanula pyramidalis*, both blue and white, good *Anthuriums*, *Begonias*, *Palms*, and *Ferns* were conspicuous, all being very tastefully grouped. Mr. G. Chislett, gardener to Mrs. Rees Mogg, Glastonbury, was second, his exhibit including several trained *Vineas* and other choice plants. The third prize was awarded to Mr. J. Golding, gardener to J. T. Hall, Esq., *Gloxinias*, *Begonias*, and *Ferns* predominating in this group. Mr. Chislett was first for *Fuchsias*, and Mr. W. Potter, gardener to A. Colson, Esq., second, and with *Zonal Pelargoniums* Mr. Potter was first and F. J. Clark, Esq., Street, second, both having creditable plants. Mr. E. Brown, gardener to C. Baily, Esq., Frome, was well first for six *Ferns*, the best of these being *Adiantum farleyense*, *Adiantum cuneatum* grandiceps, and *Adiantum cuneatum*. Mr. T. Wilkinson was a good second, and there were several creditable exhibits in this class.

Cut Roses were very fine, notably the first prize twenty-four distinct varieties, staged by Messrs. Keynes, Williams & Co. Among these were massive fresh blooms of *Ulrich Brunner*, *Mrs. John Laing*, *Charles Lefebvre*, *Her Majesty*, *A. Dickens*, *A. Colomb*, *Marshal P. Wilder*, *Duchess of Bedford*, *Annie Wood*, *A. K. Williams*, *Comtesse de Nadaillac*, *Beauty of Waltham*, *Comtesse de Serenye*, *Marie Van Houtte*, and *Duke of Wellington*. Messrs. G. Cooling & Sons, Bath, were second, their best being *Marshal P. Wilder*, *Madame Margottin*, *Mrs. J. Laing*, *Madame Lambard*, and *Comtesse de Serenye*. The third prize was awarded to Mr. W. Brown, Wells. Messrs. Keynes, Williams & Co. were

also well first for twelve varieties, among these being perfect blooms of *A. K. Williams*, *Mrs. John Laing*, *Marie Baumann*, *François Michelin*, and *Annie Wood*. Messrs. Cooling & Sons were creditably second, and Mr. F. Lindsey third. Mr. F. Lindsey was first for twelve *Dahlias*, the best of these being *Grand Sultan*, *Mrs. Langtry*, *Mrs. Gladstone*, *J. N. Keynes*, and *J. O'Brien*. Mrs. Kettewell was second. Messrs. Cooling and Sons were first for twenty-four *Asters*, staging capital quilled varieties. Mr. J. Payne, gardener to the Lord Bishop of Bath and Wells, was a good second, and Mr. J. Tbyer, gardener to H. Baily, Esq., third. Mr. E. Brown was first for twelve varieties of choice flowers; Mr. T. Wilkinson second, and Mr. W. Potter third. Messrs. Brown & Sons, Wells, had some excellent cut hardy flowering shrubs. Still more attractive were the several stands of *Tuberous Begonias* sent by Mr. B. R. Davis, nurseryman, Yeovil. Among these were several very fine named doubles, many of which were raised by Mr. Davis, as well as numerous extra large flowered single varieties.

The greatest attraction appeared to be centred in the dinner tables laid for six persons and decorated with flowers and fruit. These were set out in one of the corridors connected with the Palace, and it was much regretted that no more than three competitors entered for the prizes. Mr. J. Payne was well first, his table being very light and pretty. A centre *epergne* and two very pretty side pieces were tastefully filled with *Festuca glauca* and other Grasses, among which were intermingled a few *Eucharises*, white *Cornflowers*, and other elegant flowers. The centre of the table was covered with a square of salmon-coloured plush figured with old gold. On this were laid dark crimson *Roses* and foliage, this effectively showing off single flowers of the *Tulip Tree*. Six tastefully filled specimen glasses and four good dishes of dessert completed a very perfect table. Master C. H. Hoare, who was second, relied principally upon the foliage and flowers of the large white climbing *Convolvulus*, and other white flowers, laid on the cloth, the effect in this case also being good. Mrs. L. George was third. *Bouquets* and *vases* were also well shown.

The display of fruit was not extensive. Mr. J. Cray was first for a collection of eight, among which were fairly good *Black Hamburgh Grapes*, *Hero of Lockinge Melon*, and *Grosse Mignonne Peaches*. Mr. Payne was a good second. Mr. Cray was first and Mr. Payne second in the class for *black Grapes*, both having highly creditable *Black Hamburgh*. Mr. Cray was also first for *white Grapes* with good *Muscat of Alexandria*, Mr. T. Wilkinson being second with the same variety. With *Melons*, Mr. Payne was first for a good fruit of *Blenheim Orange*, the second prize going to Mr. E. Stokes, gardener to N. McLean, Esq. Mr. Cray was first for *Peaches*, and there were a few competitors with *Pears* and other hardy fruit.

The best collection of vegetables was staged by Mr. Hall, Mr. J. Payne being a close second, and Mr. E. Brown third. Mr. Chislett was first for a brace of *Cucumbers*, Mr. Payne second, and Mr. F. Lindsey third.

READING.—AUGUST 15TH.

THE annual summer Show of the Reading Horticultural Society was held in the Abbey ruins, by permission of the Mayor and Corporation, on the above date. The site of the Show was a most picturesque one, a huge double marquee having been erected between the thick Ivy-covered walls of the ruined Abbey. Within, high banks along each side afforded an excellent position for specimen stove and greenhouse plants, *Palms*, *Tree Ferns*, and groups, while lower parallel and end mounds were utilised with admirable effect for such brilliant flowering plants as *Fuchsias*, *Pelargoniums*, *Balsams*, and *Begonias*. Fruit, bouquets, and buttonhole flowers were arranged on central tables, and the vegetables in competition for special prizes offered by leading seedsmen were staged in a smaller side tent. Generally considered the specimens and groups were good and effective, fruit moderate, vegetables magnificent. Potatoes were splendidly shown. Onions, Tomatoes, and Cauliflowers also very fine.

Plants and Groups.—In division 1, open to all, the leading class was that for nine stove and greenhouse plants, prizes of £5, £2 10s., and £1 being offered. The first prize fell to Mr. Mould of Pewsey, whose collection included well flowered specimens of *Ericas* *Irbiana* and *retorta* major, *Dipladenia profusa*, *Ixora* *Dixiana*, *Phenocoma prolifera* *Barnesi*, and moderately good examples of *Allamanda Hendersoni* and *Gloriosa superba*. Mr. James of West Norwood had the next best group, but it was disqualified owing to his having overlooked the proviso in the schedule that two species or distinct varieties only of the same genus could be admitted, and having included three *Ericas*. A special prize was, however, awarded to him, fine examples of *Ixora* *Fraseri*, *Dipladenia boliviensis*, and *Plumbago capensis* being included in his group. Mr. Curry, gardener to Col. Pepper, Salisbury, was third. With six variegated or handsome foliage plants the last-named exhibitor carried off the premier award, his *Crotons* (*Queen Victoria*, *Weismanni*, and *Countess*) were models of health and good culture, a good *Kentia Fosteriana*, and fair examples of *K. australis* and *Latania borbonica* completing his collection. Mr. Howe, gardener to Sir R. Sutton, Benham, followed, his best plants being a fine *Latania borbonica*, *Alocasia macrorrhiza*, and *Anthurium crystallinum*. Mr. James took the remaining prize.

Mr. Dockerill, gardener to G. W. Palmer, Esq., Reading, won with six stove and greenhouse *Ferns*, the species best represented being *Alsophila australis*, very fine, *Dicksonia antarctica*, *Nephrolepis exaltata*, and *Microlepia hirta cristata*. The second prize fell to Mr. Howe, who had *Dicksonia antarctica*, *Nephrolepis davallioides* *furcata*, *Platycerium alcicorne*, and *Gymnogramma chrysophylla* in good condition; the remaining

prize went to Mr. James. A fine, healthy, and well flowered specimen of *Erica oblongata* secured the first prize for Mr. Mould in the class for one stove or greenhouse plant in flower. Mr. Bright, gardener to J. Karlslake, Esq., Whiteknights, being second with the Hon. Mrs. Hay Fuchsia. The two prizes for specimen new or rare plants went to Messrs. Woolford (gardener to A. Palmer, Esq., Reading), and Dockerill. The former was first with *Schubertia grandiflora* bearing large pure white richly scented flowers, his opponent being represented by a neat plant of *Dracena Lindenii*. Messrs. Best, gardener to C. W. Clute, Esq., Palmer and Waite, gardener to Col. the Hon. W. P. Talbot, Esq., were the prizewinners with table plants, those for *Lycopodiums* going to Messrs. Mayne (gardener to Lord Saye and Sele, Reading), and House, Southcote. These were small but very fresh and attractive. Greenhouse plants, such as *Achimenes*, *Fuchsias*, *Balsams*, *Cockscombs*, *Liliums*, *Coleuses*, *Palms*, *Pelargoniums*, and *Begonias* formed a very attractive feature, and the principal prizewinners were Messrs. Balehin, B. Simonds (Reading), Howe, Best, Midwinter, Bright, Mayne, Booker, Woolford, Dockerill, House, Mayo, and Bowerman, gardener to C. House, Esq., Hackwood Park.

The groups were a decided improvement on last year. Mr. James in particular being represented by an arrangement at once light, gay, and pleasing; that of Mr. Phippen, of Reading, who followed, was also fairly effective, but a little heavy. Mr. Sumner, gardener to — Hounslow, Esq., of Reading, was third.

Cut Flowers.—The *Phloxes*, *Dahlias*, *Roses*, *Zinnias*, &c., made a highly attractive display. Mr. Walker of Thame was first with eighteen *Dahlias*, distinct varieties, and occupied a similar position in the class for twelve, showing even, fresh, and well coloured blooms in each case. The second prizes went to Messrs. Mortimer, nurserymen, Farnham, and Cheal & Sons, Crawley. The last named exhibitors were unopposed with single varieties, but their stand was a splendid one and would have held its own in the severest competition. *Roses* were best shown by Messrs. Perkins of Coventry, who were first in both classes, minor prizes falling to Messrs. Cheal and Walker. *Hollyhocks* were passed over as not being sufficiently distinct, and the Judges recommended that in future nine varieties only instead of eighteen should be asked for. With *Phloxes*, *Asters*, *Gladioli*, double *Zinnias*, bunches of cut flowers, bouquets, and buttonholes the chief prizewinners were Messrs. Walker, Phippen, Midwinter, Woolford, House, Mould, Turton (gardener to J. Hargreaves, Esq.), Tranter of Henley, Durman (gardener to T. W. Workman, Esq., Reading), Balchin, Such, Maidenhead, and Booker. Mr. Turner of Slough, exhibited a magnificent stand of yellow ground *Picotees*, the varieties being *Colonial Beauty*, *Almira*, *Dorothy*, *Agnes Chambers*, *Annie Dundas*, and *Terra Cotta*, and the Judges recommended the award of a certificate of merit to each. Messrs. Oakshott & Millard, Reading, showed a collection of cut flowers, not for competition, and a splendid lot of cut *Roses* were staged by Messrs. Jas. Veitch & Sons, Chelsea, Messrs. Perkins also having a few stands.

Divisions 2 and 3 for amateurs and ladies comprised some interesting exhibits, but none which called for special comment.

FRUIT.—Neither in quantity nor quality could this section of the Exhibition be considered equal to that of last year, traces of the adverse season being painfully apparent. There was but one exhibitor in the class for eight dishes, distinct kinds — viz., Mr. Goodman, gardener to C. Hammersley, Esq., Bourne End. His *Grapes* *Muscat of Alexandria* and *Black Hamburg* were but moderate, but the *Neectarines* and *Peaches* were very good. *Plums* (*Kirke's*) and *Apricots* (*Hemskerk*) were of fair quality, but the *Figs* (*Brown Turkey*) were moderate. Mr. Maher, gardener to A. Waterhouse, Esq., Yattendon, was awarded the first prize for a collection of six, but there was no opposition. He showed *Gros Colman* and *Foster's Seedling Grapes* fairly well, *Elruge Nectarine*, *Hero of Lockinge Melon*, and *Singleton Fig* moderately, and a good dish of *Morello Cherries*. *Black Hamburg Grapes* were best shown by Mr. Osman, gardener to J. Baker, Esq., Ottershaw Park, the bunches being of medium size, well ripened, and well coloured. Mr. Turton's second prize clusters were good in point of size, but unfinished; Mr. Kneller, gardener to W. S. Portal, Esq., Malshanger Park, being a poor third. For a similar number of bunches of any other black kind Mr. Osman was first with *Alicante*, well coloured, but the berries somewhat small; Mr. Waite, second with *Gros Maroc* in fair condition; and Mr. Maher, third with *Madresfield Court*. The last named was to the fore with white *Muscats*, the berries small, but well ripened. Mr. Ashby, gardener to Mrs. Fanning, Whitechurch, was second, and Mr. Osman third, the bunches in each case being of good size, but not well ripened. For any other white *Grape* Mr. Maher was once more to the front, showing *Buckland Sweetwater*, moderately good; Messrs. Kneller and Turton following. Mr. Pounds, gardener to G. May, Esq., Caversham, was first with six *Peaches*, one variety; he was represented by very fine well ripened fruits of *Neectarine*. Messrs. Waite and Mortimer were second and third. Mr. Goodman won with *Neectarines*, showing *Lord Napier* fairly, but the opposition was weak; Mr. Bowerman was second, and Mr. Waite third. *Apricots* were unripe, and only the third prize was awarded, a poor dish of *Moor Park* winning this for Mr. Howe. The latter was the only exhibitor of *Figs*, and was placed first for *Brown Turkey*. With *Plums* Mr. Goodman won, his opponents being disqualified for duplicates. It was too early for *Apples* and *Pears* to be shown in anything like the proper condition. Messrs. Hinton, gardener to J. Leslie, Esq., Reading; Turton, Howe, House, Goodman, and Read, gardener to F. Wilder, Esq., were the prizewinners. Mr. Goodman won with a collection of miscellaneous fruits, followed by Mr. Read. These deserve a word of commendation, Mr. Goodman having a basket of about

twelve kinds, all in good condition. Messrs. Sutton & Sons, Reading, offered four prizes for the best single specimens of either of their three *Melons*, *Scarlet Invinible*, *Imperial Greenflesh*, and *Hero of Lockinge*, but the last named variety represented the prizewinner in each case. Mr. Kneller was first; Mr. Palmer, gardener to Hume Dick, Esq., Thames Ditton, second; Mr. Maher, third; and Mr. Hashim (gardener, Mr. G. Swettenham), Calcot, fourth.

VEGETABLES.—These were the finest feature of the Show, some splendid produce being exhibited for prizes offered by several large seed firms. Messrs. Sutton & Sons offered five prizes for collections of vegetables, six distinct varieties, to include several of their specialities. Mr. Kneller won the first prize of £3 3s. with a very fine lot, comprising *Veitch's Autumn Giant Cauliflower*, very fine indeed, *Matchless Marrow Peas*, *Rousham Park Onion*, *Snowdrop Potatoes*, *New Intermediate Carrots*, and *Perfection Tomatoes*. Mr. Waite showed *Perfection Tomatoes*, *Satisfaction Potatoes*, *Duke of Albany Peas*, and *Intermediate Carrots* of very high quality, and had a very close contest with Mr. Kneller, but had to put up with second place; Mr. Bowerman was third, also showing well; Mr. Lye, gardener to W. H. Kingsmill, Esq., fourth; and Mr. Pope, gardener to the Earl of Carnarvon, High Clere, fifth. *Potatoes* were splendidly shown, Mr. Pope being first for nine dishes (Sutton's), with *Lady Truscott*, *Reading Russet*, *Early Regent*, *Early Border*, *First and Best*, *Satisfaction*, *Reading Ruby*, *Woodstock*, and *Prizetaker*. Mr. Flott, gardener to Major Alfrey, was a creditable second, the remaining prizes going to Messrs. Lye, Palmer, Read, and Springbett, Sulham. With seven specified varieties (Sutton's prizes), including several of those already named, Mr. Flott was first, Messrs. Pope, Lye, and Read following.

Messrs. Carter & Co. offered prizes for the best nine dishes of vegetables grown from their seed. The first fell to Mr. Lye, who showed *Standard Bearer Celery*, *Stratagem Peas*, and *Model Cucumber* excellently amongst others. Mr. Beckett was second, and Mr. Waite third.

Mr. C. Fidler, Reading, offered prizes for collections of *Potatoes* and six distinct kinds of vegetables, Messrs. Pope, Beckett, and Lye being first, second, and third in the order named in each case.

Messrs. Webb & Sons, Wordsley, Stourbridge, offered prizes for the best collections of six distinct kinds, to include two of their varieties. Mr. Lye was first with a very fine lot, including *Monster White Onion*, *Early Puritan Potato*, and *Chancellor Pea*, very good indeed; Mr. Waite was second, *Stourbridge Glory Potato*, *Kinver Cauliflower* being good; Mr. Kneller was third, and Mr. Rye fourth.

Messrs. Oakshott and Millard's champion prize for the best dish of fruit in the Show was carried off by Mr. Goodman's exhibit, while the champion prize offered by the same firm for the best dish of vegetables was won by Mr. Chamberlain with *Satisfaction Potato*.

ST. ALBANS.

THE above Society held its second annual summer Show on the 15th inst. The Exhibition was in itself a success, and showed a marked improvement on that held last year. The improvement was specially noticeable in the cottagers' division. From some parts of the Society's district vegetables were sent which would well have held their own on any exhibition table. There is also a marked improvement in the general cultivation of the allotments, while the interest the various holders of allotments take in the Society is plainly shown by the fact that eighty-four entries were sent in for prizes offered by the Society for the best kept and cultivated allotments. Including the entries for allotments there was something like 900 entries for the Show itself. This must be very gratifying to the promoters, and also to the very energetic Hon. Sec., Mr. W. F. Emptage. Last year the Society had to depend to a great extent upon non-competitive exhibits, the funds not permitting an open class, or a class in which gentlemen's gardeners could exhibit. This season, however, they were enabled to offer several prizes open, the result being that there was a fair competition amongst the gardeners of the neighbourhood. Owing, no doubt, to the very backward season fruit was not well represented, the most prominent exhibits being the *Muscat of Alexandria Grapes* from Mr. Nutting, gardener to J. B. Maple, Esq., M.P.; *Black Hamburgs* by Mr. Faint, Maiden Hill, Hertford; *Peaches* and *Melon* shown by Mr. Nutting. *Exotic Ferns* were well shown by Mr. Emptage, gardener to J. S. Hill Esq., Hawkswick, St. Albans, and by Mr. Nutting. The exhibits in this class were exceedingly close, each lot finding a deal of favour with the visitors. The Judges, however, placed the *Hawkswick* collection first. In the six foliage plants the decisions were reversed, Mr. Nutting being a good first. The same exhibitor was also well to the fore with twelve table plants, being an easy first. Mr. Nutting also secured the first for four stove and greenhouse plants in bloom. In the competition for groups for effect there were four entries. Mr. Shaw, gardener to Rokeby Price, Esq., Clementhorpe, St. Albans, was placed first, Mr. Emptage second, Mr. Nutting third. None of the groups call for any remarks, the first and second being huge closely packed banks of plants, while that from Mr. Nutting showed a want of finish.

Vegetables were well shown by Mr. Faint, Mr. Pepper, gardener to G. Burnand, Esq., Tewin Water, Welwyn, and Mr. Reynolds, gardener to — Green, Esq., Oaklands, St. Albans. Mr. Pepper also secured Messrs. Cutbush's prize for *Mushrooms*. In the amateurs' classes the exhibits were highly creditable, while, as before stated, the cottagers' exhibits were exceptionally good. Messrs. W. Paul & Son, Waltham Cross, staged some fine *Roses* in their well known effective style. Messrs. Cutbush & Sons had a fine group of plants, in which were some good plants of *hardwooded Heaths*. They also staged several good boxes of

Roses. Messrs. Watson, New Zealand Nurseries exhibited some exceedingly fine single Begonias. Mr. Spriggins also assisted with a good display of Roses and plants; and Messrs. Wood & Son, Wood Green, showed samples of their various specialties.

SUTTON (SURREY).

THE Sutton and Cheam Horticultural Society held their twenty-fifth annual Show on the 15th inst. in the charming grounds of H. L. Antrobus, Esq., at Lower Cheam House. There was a large attendance of visitors; the weather being all that could be desired induced many from Croydon and the surrounding district to visit one of the best shows this Society has yet had. The well kept pleasure grounds, kitchen gardens, and the houses, which are under the able management of Mr. T. Knowles, the gardener, were open to all who cared to "look round," and hundreds availed themselves of the opportunity, proving how much the kindness of Mr. and Mrs. Antrobus was appreciated. Mr. W. King, gardener to Philip Crowley, Esq., Waddon House, Croydon, was to the front again in the class for twelve stove and greenhouse plants, having fresh and admirable grown specimens of *Dracæna Lindenii*, 10 feet high, furnished with leaves to the pot; *Alocasia macrorrhiza variegata*, 10 feet through; *Anthurium crystallinum*, 6½ feet through; and *Anthurium Andreanum*, with fifteen spathes; his other plants being among the best to be seen near the metropolis. Mr. T. N. Penfold, gardener to Canon Bridges, Beddington House, was a good second, his foliage plants being large and healthy, but the flowering ones were not so good as usually shown by him, excepting *Statice profusa*, which was well bloomed. For a specimen plant in bloom, Mr. King was again first with a magnificent *Clerodendron Balfourianum*, loaded with bloom. The same exhibitor was first for six exotic Ferns, *Davallia fijiensis plumosa*, *D. polyantha*, *Asplenium nidus-Avis*, and *Woodwardia radicans*, all large and well-matched plants; G. Smith, gardener to G. Orme, Esq., and Mr. J. Acock, gardener to G. A. Bacon, Esq., following with smaller plants. Mr. King always shows *Selaginellas* in remarkable condition, and for six of these he was deservedly placed first, and Mr. Smith second. Mr. S. Broughton, gardener to W. F. Hughes, Esq., Sutton, took all the leading prizes for *Fuchsias*, *Balsams*, *Cockscombs*, and *Gloxinias*; he was also a successful exhibitor in the classes provided for local gardeners only.

The greatest attractions were the groups of plants arranged for effect, Mr. King taking first honours with a light and graceful arrangement. Several *Cattleya Gaskelliana* were peeping out of the groundwork of *Maidenhair*, and at the back stood a large plant of *Dracæna Lindenii*, bearing a flower spike 2 feet in length. Mr. T. A. Glover, gardener to E. Ellis, Esq., Manor House, Wallington, was a close second. In the centre was a finely flowered *Oncidium Laneanum*, *O. crispum*, and *Odontoglossum Alexandræ*, with some choice *Begonias*, were conspicuous. In another class, from which nurserymen were excluded, G. Flemwell, Esq., Sutton, was the only exhibitor, but he merited the award of the first prize, and was doubtless disappointed to find he had no competitors to defeat.

The principal prizetakers for cut flowers were Mr. W. Slade, gardener to G. Foster, Esq.; Mr. A. Carter, gardener to Alderman Evans, Ewell, for herbaceous cut flowers, the latter being first again for both *Asters* and *Dahlias*. Mr. King and Mr. Penfold had the best two collections of twenty-four varieties of cut blooms. Several boxes of *Roses* were staged, Messrs. Broughton and Penfold taking the lead with blooms of good quality, considering the lateness of the season.

Fruit was not so good as generally shown here, but the Peaches from Mr. Carter and the Nectarines from Mr. G. Smith were large and well coloured. Vegetables were well represented, Mr. Osman, from the South Metropolitan District Schools, showing in his usual good style, followed by Mr. Blurton, gardener to H. Cosmo Bonsor, Esq., M.P., and Mr. Spinks. The amateurs and cottagers were in good force, especially the latter, as their productions were plentiful and good, which rendered the smaller tent an important part of the Exhibition.

Several nurserymen and others assisted with plants and flowers to make the Show a success. Messrs. J. Laing & Sons, Forest Hill, had a tastefully arranged group containing bright flowering *Begonias*, &c., a telling plant being their new white *Anthurium Laingi*. Seedling *Hollyhocks* of merit and *Roses*, including good blooms of Mrs. J. Laing, Alfred Colomb, and Her Majesty. Mr. J. Appleby, Dorking, had also good boxes of *Roses*, as had Mr. J. Peed, Roupell Park Nursery; good blooms of A. K. Williams, Captain Christy, Pride of Waltham, and White Baroness were the best. From Messrs. Thompson & Son, Wimbledon, came a choice assortment of 100 bunches of hardy and herbaceous flowers, including Iceland Poppies, *Geum coccineum*, *Chelones*, *Harpalum*, *Gaillardias*, *Potentillas*, and *Phlox*; this exhibit was much admired. Mr. J. Box, Croydon, had a capital group of plants, his named and seedling *Begonias* being large and showy; he also had a collection of Turner's new *Carnations* and *Picotees*. Mr. T. Butcher, Croydon, exhibited a fine lot of Shirley Poppies in variety of colour. Messrs. Cheal & Sons, Crawley, and Mr. E. Morse, Epsom, both showed well, the former having some grand boxes of *Dahlias*. From the gardens of the Right Hon. G. Cubitt came ripe fruit and foliage of *Monstera deliciosa*. Six large well coloured bunches of Black Hamburgh Grapes came from Mr. Beckett, gardener to T. R. Bryant, Esq., Juniper Hall. To Mr. J. Flemwell (Chairman of the Committee) and Mr. W. R. Church (the Secretary) much credit is due, and each year these gentlemen appear to be taking more interest in and working harder for the benefit of the Society. Money boxes were placed in the tents by the local secretary of the Gardeners' Orphan Fund, and many gave their mites.

TAVISTOCK.

IT is forty years since the Tavistock Cottage Garden Society came into existence. Its first exhibition and several subsequent ones were held in the assembly rooms of the "Bedford Hotel;" a move was afterwards made to the Corn Market, until the show grew to such proportions that the market hall was not too large for the display of its wealth of flowers, fruit, and vegetables. Under the supervision of Messrs. H. Spry, E. Cornelius, T. Palmer, H. Blatchford, and S. J. C. Blanchard the building was tastefully and skilfully embellished. From the ceiling gay banners and moss-covered baskets of Ferns depended, and the arcades were decorated with evergreens, which were studded with rosettes and surmounted with flags; a fountain, as usual, played in the centre of the building. There was a falling off in the number of exhibits from the conservatories of gentlemen residing in the neighbourhood, only four being represented—namely, Mr. D. Radford, of Mount Tavy; Mr. F. Bradshaw, of Lifton Park; Mr. E. Marshall, of Parkwood House, who is the President for the year; and Mr. Turner, of Morfe Lodge, Tavistock. The florists who had stands were Mr. Yole, of the Tavistock Nursery; Messrs. Lecombe, Pinee & Co., of the Exeter Nursery; Messrs. Hender & Son of Plymouth; Mr. Williams of Compton, Messrs. Dingle of Saltash, and Messrs. Curtis, Sanford & Co., of the Devon Roseries, Torquay. The flowering plants made a magnificent display, and there was a decided improvement in the way in which some of them were arranged. The fruit department showed a slight falling off, and there was a marked diminution in the number of cut flower exhibits. This was no doubt largely attributable to the unfavourable season, but it has also been suggested that the money prizes are not large enough in amount to induce hearty competition, and it may be well for the Committee to consider the advisability of giving larger sums next year. The vegetables were a splendid collection, and the quality of the baskets of mixed vegetables were so high that the Judges experienced great difficulty in awarding the prizes. The stand containing the floral exhibits of Mr. F. Bradshaw, of Lifton Park (gardener, Mr. G. H. Mounsdon), occupied its old position at the further end of the building. The arrangement of the stand was remarkable for the judicious admixture of flowers with Ferns, and the whole of the specimens were well grown. The *Achimenes* were the best in the Show, also *Plumbago capensis*. A choice show of *Begonias*, *Adiantums* in varieties, and *Coleuses* were also particularly noticeable. On one of the central stalls stood the principal part of the collection of Mr. E. Marshall, of Parkwood (gardener, Mr. C. Chanter). It was an excellent stall of plants, comprising *Begonias*, ornamental foliage plants, Ferns, and *Geraniums*. The stands, however, appeared at a disadvantage on account of the limited space at the command of the gardener for effective arrangement. A supplementary stall at the side of the main one contained a beautiful collection of seedling *Gloxinias*. The exhibits on the stands of Mr. D. Radford of Mount Tavy (gardener, Mr. Lowday), were of great merit, and the grouping was excellent, but had the staging been carried higher its contents would have been shown to greater advantage. Its speciality consisted of a number of well-grown ornamental foliage plants. A very fine *Adiantum farleyense* was especially worthy of notice, as were also some well-grown specimens of *Geraniums*, *Colosias*, *Achimenes*, *Fuchsias*, and *Cockscombs*. Mr. Turner, of Morfe Lodge, Tavistock, also exhibited a stall of well-grown plants, consisting principally of *Begonias* and Ferns.

The largest and most attractive display sent by florists was that of Messrs. Lecombe, Pinee & Co., of the Exeter Nursery. It contained some fine Palms, *Erias*, *Allamandas*, and *Dipladenias*; also some excellent *Oreids*, including the *Cattleya crispa*, the *Cypripedium Lawrencianum*. Among the ornamental foliage plants was the *Alocasia Sanderiana*, and the cut blooms embraced choice *Carnations*, *Picotees*, a box of *Phloxes*, and another of *Roses*, among the mixed herbaceous plants being a specimen of the new *Gaillardia maxima*, and also *Wahlenbergia grandiflora alba*. The exhibits of Mr. E. Yole of the Tavistock Nursery included some particularly fine *Dahlias* in twenty-four distinct varieties, *Carnations*, *Marigolds*, *Antirrhinums*, and the finest collection of *Begonias* in the Show, the flowers and foliage being remarkably well developed. They were in fourteen distinct colours, including pure white, orange scarlet, dark pink, and salmon, the whole being tastefully bordered with Ferns. Messrs. Curtis, Sanford & Co. of the Devon Roseries, Torquay, were represented by magnificent specimens of the best varieties of the "queen of flowers." Their *Dahlias* were also very fine. Messrs. J. Dingle & Son, of St. Stephens, by Saltash, showed a good collection of *Petunias*, *Carnations*, *Pelargoniums*, *Verbenas*, *Pansies*, *Dahlias*, *Abutilons*, *Pentstemons*, and *Gaillardias*. The stand of Messrs. Hender & Sons, of the Mannemead Nurseries, Plymouth, was remarkable for its rich variety of *Petunias*; they also showed some good specimens of *Pampas Grass*. Mr. J. R. Williams of the Compton Nursery, Plymouth, exhibited a model fernery, suitable for a fire-screen. It had reflectors at certain angles, each of which reflected the plants placed in the fernery, producing a very charming effect. He showed a plant of *Amorphophallus Rivieri*, and his other specimens included a Japanese Poppy (the Mikado), *Fuchsias*, and *Coleuses*. Messrs. Monk and Waldron were the only exhibitors who sent plants for competition, which were well grown. The cut flowers most worthy of mention were the *Pompon Dahlias*, the *Pelargoniums*, the *Asters*, the *Marigolds*, and the *Roses*.

Turning to the vegetables, as we have already stated they were of an exceptionally good quality. The number of dishes and plates of Potatoes was larger than last year, and no one would think, judging from the excellence of the specimens in the Exhibition, that the season had

been such a disastrous one. The Cos Lettuces and the Scarlet Runners were of an indifferent description; of the last-named there were very few exhibits. The Carrots were fine. The Cauliflowers were the best that have been seen in a Tavistock exhibition for many years, and the Broad Beans were of extraordinary length, some measuring 15 inches. Of the baskets of vegetables we cannot speak too highly. They evoked the greatest admiration, and as the Judges found it a task of such difficulty to award the prizes, it must have been very satisfactory to them, and it could not fail to have inspired confidence in their decisions, when it was discovered on comparing results that W. Palmer, W. Thorne, and S. Miles, who took prizes in the order named for the best kept gardens were also recipients of the first and second prizes for baskets of vegetables, Messrs. Thorne and Miles being equal in this competition. In the fruit department three fine bunches of Grapes were exhibited by Mr. Marshall, and two bunches by Mr. D. Radford. Messrs. Dingle and Sons sent some exceptionally large Black Currants and Gooseberries. In the competitive classes the exhibits were of a creditable description. A large Melon was exhibited by Mr. W. H. Tuckett, of Mannamend, Plymouth, and three fine ones by General McArthur, of Brooklands, not for competition. Mr. R. B. E. Gill contributed £10 towards the prize list for the best kept cottages in the town and country, and there was plenty of competition. There were no exhibits of honey, although prizes were offered, but some excellent specimens of butter and cream were shown. The highly satisfactory manner in which the arrangements for the Show were carried out was in no small degree due to the untiring energy of the Secretary, Mr. H. E. Monk.—(*Tavistock Gazette*.)

CUCKFIELD COTTAGERS' SOCIETY.

THIS flourishing Society held its twenty-seventh annual Show on Wednesday, the 15th inst., in the vicarage field. This is simply a cottagers' Society, including the districts of Haywards Heath and Staplefield, the parishes of Balcombe, Bolney, and Slaugham, and is chiefly supported by the liberal donations of the resident ladies and gentlemen of those parishes, whose subscriptions amount to something like £70 or £80 annually. The Committee is composed of representative gardeners from each parish and tradesmen and others of the town of Cuckfield. Cuckfield cottagers have always been noted for their vegetables, and the present occasion was no exception of the rule. There were eighty exhibitors came forward, and the entries were 938, nearly 200 more than last year. Potatoes were well represented. In six classes there were 140 entries, which, with those entered for special prizes, made close upon 250 plates of splendid Potatoes. Broad Beans, Peas, Turnips, under-ground Onions, and Celery were very good. Runner Beans, Carrots, Parsnips, and spring-sown Onions were not so good as those produced last year on the "dry system." Small fruit was fairly well shown, but Apples and Pears were a poor lot. There is also an amateurs' class, but when the fruits, flowers, and vegetables shown by them are compared with those of the cottagers, one is obliged to come to the conclusion that the former would cut a poor figure in the prize list were the two sections amalgamated.

The centre stage in the cottagers' tent was filled with fine collections of plants kindly sent by R. A. Bevan, Esq., Horsgate (Geo. Stringer, gardener), who staged by far the best lot of plants, and they were as effectively arranged as they were well cultivated. W. Payne, Esq., Hatchlands (T. Burtinshaw, gardener); T. W. Erle, Esq., Mill Hall (H. Seutt, gardener); G. Knott, Esq., Knowle Lodge (W. Stovell, gardener); T. W. Best, Esq., Harvest Hill (J. Singley, gardener); and F. Huth, Esq., Hinmead Hall (T. Feist, gardener), also sent good groups of plants, all arranged in this tent. In the amateurs' tent similar exhibits of plants came from T. T. C. Lister, Esq., Borde Hill (R. Inglis, gardener), and Mrs. Meberly Mytten (J. Mitchell, gardener), while a fine lot of plants and cut flowers from Messrs. Balchin & Sons, Hassocks; several fine boxes of Roses from Mr. Piper of Uckfield; collections of dried grasses and hardy flowers, &c., from Messrs. Roots, Cuckfield; and a miscellaneous collection of Dahlias, plants, &c., from Messrs. Cheal & Sons, Crawley, made up a display well worthy of the town and district.

A few special prizes are offered for gentlemen's gardeners. Mr. Manton, gardener to Mrs. Clifford-Borrer, Bolney, secured Messrs. Sutton's prize for a tray of vegetables with splendid samples, all good. Mr. J. Mitchell was first for a similar prize given by Messrs. Cheal and Sons. Mr. Stringer was awarded Mr. Pannett's (of Chailey) prize for twelve Dahlias, with fine blooms for the season. Messrs. Balchin's prize for black Grapes was easily won by Geo. Warren, gardener to Mrs. Hankey, Balcombe Place, with well coloured, though rather loose, bunches. Mr. T. Burtinshaw was awarded Mr. Piper's prize for twelve Roses. Here let me state a fact not quite creditable to the tradesmen of Cuckfield. Out of nine special prizes offered only two are given by men residing in the district. The Show was well attended, and the receipts at the gate satisfactory. The duties of Secretary was ably carried out by J. Tugwell, sen.

PORTMADOC.

THIS excellent Society held its ninth annual Show as above in the park in what may fitly be termed Queen's weather. On the whole the exhibits were neither as numerous, nor perhaps as meritorious, as have been brought together here in former years, a variety of circumstances contributing towards this result. The Society is, however, in a flourishing condition, and promises well for future successes.

Mention should be made of special awards given by Messrs. Barr and Sen, London; Messrs. Daniels Bros., Norwich; Messrs. W. Clibran and

Son, Altrincham and Manchester; and Mr. T. Cumming, which elicited a good competition.

Several meritorious stands were put up "not for competition," R. M. Greaves, Esq., Wern, having a choice collection of Ferns and Palms. Mrs. Osmond Williams, Dendroth Castle, most tastefully arranged water bouquets and decorative plants, reflecting credit upon her able gardener, Mr. Ward. Trade exhibits were confined to Messrs. Dickson, Chester, and Messrs. W. Clibran & Son, Oldfield Nurseries, Altrincham, the former with stands of cut Roses and herbaceous flowers in their usual style, and the latter with a large stand of decorative, foliage and flowering plants coming in for unstinted attention, and some stands of Roses highly creditable for such a season. From their cut flower depôt also an exhibit of special merit was sent, consisting of wreath, anchor, and bouquet, all of which were greatly admired.

The fruit exhibited was certainly good, first for black and white Grapes falling to, and well merited by, J. E. Greaves, Esq., Crickieith (Mr. Morgan, gardener), second in both cases secured by J. Vaughan, Esq., Nannau (Mr. Cooke, gardener), with excellent bunches but not quite so well finished. Peaches.—Mr. Cooke was well to the fore here, Mr. Pereival being second. H. J. Ellis Nanney, Gwynfryn, was first with a green fleshed Melon (Mr. Roberts, gardener); Lady Ewing, Bettws-y-Coed, first with a scarlet flesh; Mr. Townhend (gardener, Mr. Roberts), taking second.

In the plant classes we come upon three Achimenes, which secured for Mr. Roberts, gardener, Gwynfryn, first prize, and which for size, training, and bloom were admirable. Other successful exhibitors in plants were J. E. Greaves, F. S. Pereival, R. Pugh Jones, Ynysgain, Mrs. Osmond Williams, Lady Ewing, and R. M. Greaves.

Cut Flowers.—Capt. Wynn Griffith, Llanfair Hall, took first honours with Asters and double Dahlias (J. Ellis, gardener); Carnations, D. Homfray, Esq., Portmadoc. Pansies.—Mr. Cooke, Nannau, as usual took first; second, J. M'Lean, Minford. Collection of Cut Flowers.—First, Mr. Cooke; second, Miss Rae, Tanybwch; third, Capt. Wynn Griffith. Buttonhole Bouquet.—First, Mr. Cooke; second, F. S. Pereival. Bridal Bouquet of Outdoor Flowers.—First, Mr. Cooke; second, F. S. Pereival; third, Mrs. Osmond Williams. Bouquets of Stove and Greenhouse Flowers.—First, F. S. Pereival; second, R. P. Jones.

Vegetables are always strongly shown, this year being no exception, amateurs and cottagers being particularly good. It is sufficient testimony to the good work of the Society to see the exhibits that are brought here annually, and to see throughout the season the humblest cottager improving his own and no less his neighbour's condition by striving hard and constantly for the honour of winning a prize or series of prizes on the great show day.

One of these hardworking men carried proudly away from the Show no less than nineteen prizes, notwithstanding the keen competition. One of the old-hand gardeners, too, is to be congratulated on taking away thirteen prizes, ten of them being first.

KITCHEN GARDEN.

LIFTING AND STORING EARLY POTATOES.—The disease we anticipated some weeks ago has come, and some varieties are badly affected. Some of the early ones have escaped; the latest are not touched, but the second early and midseason sorts are the worst. Unfortunately these are not ripe, or we should advise their being dug up and stored at once; but it would be a mistake to do this until they are matured, but all early Potatoes should be lifted and stored at once. When the weather is favourable let them remain in the air for a few hours after lifting to dry, but do not expose them to much light afterwards. Remove any affected with disease, and store all that can be secured. We have been so exempt from disease for a few years that little attention has been given to it of late, but this year is a disagreeable reminder, and those who cultivate a large quantity of early Potatoes will be lucky. Indeed, there is no better way of securing a crop free from disease than to grow a large proportion of early ones, and all who suffer from the disease this year should bear this in mind at planting time next spring.

OLD CABBAGES.—Plants which have been heading during the summer are now over, and the question is what to do with them. If other kinds of winter greens are good and plentiful the Cabbage stumps may be drawn up and thrown away, and the ground filled with winter Spinach or some other crop; but if vegetables for the early winter are likely to be scarce the Cabbages should be kept, as they will produce many side shoots that will form useful little heads, and these are valuable in times of need. When it is decided to do this the decayed leaves should be cleared from them and the weeds hoed out. Some time ago we planted some spring-sown Cabbages. These are about half grown now, and by October they will be ready for use; but we are never in a hurry to throw the old plants away, as they frequently turn in most useful when vegetables are scarce.

AUTUMN ONIONS.—Onions sown last year did not bulb very well in

the fore part of the summer, but of late they have swelled rapidly, and at the present time we have bulbs of Trebons weighing 1½ lb. This is a grand Onion for sowing in autumn; indeed it is the best, and we have just sown 6 ozs. of seed. Giant Roeca is the commonly sown variety, but in many cases it splits and fails before the bulbs are really in good form, and it does not keep very well; we are not sowing it this autumn, but put in a few White Tripoli for the early crop and depend on Trebons for the main supply. All matured autumn Onions should now be drawn and cleared from the ground, but only the best should be stored. They must be laid in the sun for a time before cutting off the stems.

CELERY.—We are never troubled with Celery bolting, but some complain of it, and where many of the plants are running to seed they may interfere with the supply, as seedling plants are useless at all times; and if late plants have been retained in the seed bed a quantity should be planted out to take the place of those that are seedling. A deficiency of Celery is often severely felt in the kitchen, and the supply should be kept up by all means. The American White Plume is now ready with us. It is really very good, and as it requires no earthing up it may be cultivated very cheaply. Plants intended for use in October and November should not be fully earthed up, but late plants need not be earthed until they have gained considerable size.

WINTER TURNIPS.—Turnips always bulb best when well thinned, and although it is very necessary to thin them freely in summer, it is still more so with the winter crop. Those intended for winter have been thinned once, and they are now 4 or 5 inches apart, but this is much too close, and we are about to thin them all to 15 inches apart. This is a good distance for winter Turnips, and it is much better to thin them when small than allow them to grow and then find they are too close. Bulbs produced in this way are never so fine or hardy as those properly thinned out from the first.

RUNNER BEANS.—We never knew Runner Beans to be so scarce in August as they are this year. Some pods are much in advance of others, and all of these forward pods should be carefully gathered at once. If left they would soon become too old and check the main supply which is yet to come. Should the weather remain dry a good soaking of liquid manure occasionally would greatly benefit the crop.

GLOBE ARTICHOKE.—Cut the old stems from these, and should all the heads not have been used and some of them become too old remove them also, as by doing this some of the forward growths may be induced to throw up young stems, which will produce small useful heads in October or November.

SOWING CAULIFLOWERS.—Where Cauliflowers are wanted early in the spring a good mode of securing them is to sow the seed in the autumn, winter the plants in a frame, and have them ready for planting the first opportunity in spring. The present is the proper time to sow. We prefer sowing the seed in a little bed on a warm sunny spot in the open, lifting the plants and putting them in the frames in October, to the plan of sowing them in a frame altogether. Plants raised in the open are always robust and generally pass the winter well. The secret of having good Cauliflower plants in spring is to keep them hardy in autumn and never protect them until it is necessary to do so.

FRUIT FORCING.

VINES.—*Earliest House.*—Trees in this house will be casting their leaves, and should have all the ventilation practicable, and the border allowed to become as dry as is consistent with preservation of the roots. The Vines should be pruned at the end of the present or early part of next month at the latest, the house thoroughly cleansed, repaired, and if required painted, the Vines being dressed, removing no more than the loose bark, and washing the rods with a solution of softsoap, 8 ozs. to the gallon of water. If there be any scale or mealy bug a wine-glassful of petroleum may be added, with flowers of sulphur to bring it to the consistency of cream. Apply it to every part, after mixing thoroughly with a brush. The borders, both inside and outside, should be cleared of the old mulching material and the loose surface soil, and have a top-dressing of turfy loam, with about a fifteenth part of bone dust incorporated. If the border be dry a moderate watering should be given, and the house kept as cool as possible.

Houses Started Late.—This is a great mistake, particularly when the varieties are late, which as a rule require a long time to ripen, necessitating, especially in a season like the present, sharp firing to have the fruit well ripened by the middle or end of next month at latest. Maintain a night temperature of 65° to 70°, to 75° or 80° by day up to 85° or 90° with sun, this being the period to make up for lost time instead of deferring firing until the Grapes show colour, as they may not do until September is well advanced, prolonging the ripening into October or later. Grapes so ripened do not keep plump or satisfactory to a late period. The atmospheric moisture, as well as that at the roots, must be kept up in proportion to the condition of the Vines and the temperature maintained, accompanied with free ventilation so as to accelerate the ripening process. Vines in other houses that were started in good time will be well advanced towards ripening, and should have the atmospheric moisture reduced gradually without giving more fire heat than is necessary to keep up a circulation of dry warm air, to secure well-ripened wood and highly finished fruit.

Vines from which the Grapes have been cut must have all the laterals closely stopped, and a dry warm atmosphere with abundant ventilation maintained to insure the thorough maturation of the wood. With a view to the preservation of the foliage, give a good washing

with the garden engine on fine evenings, especially if there be traces of red spider.

PINES.—Suckers obtained from the summer fruiting plants will soon be ready to be repotted. Transfer the strongest to pots 10 and 11 inches in diameter according to the variety, affording the plants a position near the glass in a light airy house, keeping them gradually growing throughout the winter months, under which conditions they will start into fruit readily about the following May or June, and afford a good supply of early autumn fruit. The remaining portion of the plants above referred to should be wintered in 7 or 8-inch pots, and placed in larger pots in spring. These, with suckers of Smooth-leaved Cayenne and Charlotte Rothschild started last March, will without much difficulty provide a successional supply of ripe fruit throughout the winter months, and be supplemented by Queens and others which were started at the same time. At this period of the year it will be necessary to effect a re-arrangement of the plants which were started as suckers last autumn, many of the free-fruited varieties now having fruit swelling; and these should be separated from the others, as plants not in that condition will by this time have completed their growth, and will more readily start into fruit at the required time by subjecting them to more liberal ventilation during the next six weeks when the temperature exceeds 80°, the temperature at the roots being kept at 75° to 80°. For plants that have been recently repotted 90° at the roots is suitable, but for plants well established a mean of 80° is best. When fruit is swelling the atmosphere should be kept moderately moist, and a little air admitted at the top of the house early in the morning to dispel superfluous moisture before the sun's rays act powerfully on the fruit. Ripe fruit required to be kept must be moved to a shady house and have abundant ventilation. Shading should be dispensed with except for rootless suckers.

MELONS.—In pits and frames the last plants will have set or be setting their fruits. Ours are well set, the atmosphere having been kept dry, and are swelling away freely. We now sprinkle the plants with tepid water and close early in the afternoon at 80° to 85°, admitting air at 75°, increasing with the advancing sun heat to 85° or 90°. Those in frames should be attended to as required with linings of sweetened fermenting material as the nights become cold, so as to prevent the temperature falling below 65° in the morning, and if mats are placed over the lights after the sun leaves the frames, and removed shortly after the sun has risen, very much better results will be had with late Melons than usually results from frames.

Maintain a night temperature of 60° to 70° at night, and 75° by day in Melon houses heated by hot water. As the days are shorter lessened supplies of water will be required, yet give sufficient to keep the soil in a moist state whilst the fruit is swelling, but after it is full sized or ceases swelling afford no more than to maintain the foliage from flagging. Keep the laterals well stopped to one leaf, and rub off superfluous shoots as they show, allowing nothing to interfere with the principal leaves or to retard the swelling of the fruit. Plants with fruit advanced for ripening should be kept dry at the roots and have air very liberally, with, if practicable, an advance of temperature, avoiding a close moist atmosphere, which invariably results in cracking of the fruit or inferior flavour. The last plants will have been placed in houses and are growing freely. The leader must not be stopped until it reaches the trellis, when it may be pinched out if more than one leader is wanted, or may be allowed to grow two-thirds of the distance up the trellis if only one leader is wanted, and then be stopped, removing every alternate lateral directly they can be handled. Maintain a moist and warm atmosphere—70° to 75° by artificial means, with the bottom heat at 80° to 85°. Keep a sharp look out for canker at the collar and upon the stem, rubbing quicklime well into the parts affected, striving to maintain a clean growth and healthy collars to the last.

PLANT HOUSES.

Camellias.—The earliest plants will be swelling their flower buds rapidly, and weak stimulants will prove beneficial. They need assistance more at this than at any other stage of their growth. Strong stimulants should be avoided, for they are liable to overforce the plants, with the result that the buds will eventually fall. Weak stimulants, such as clear soot water, light sprinklings of Clay's fertiliser, or that made from cow manure liberally diluted with water may, with advantage, be given weekly until the flowers commence expanding. The utmost care must be taken that the plants receive no check or disappointment will follow. Water liberally and syringe freely twice during the day. Disbudding may be practised at once by the removal of all small and badly placed flower buds. If insects exist upon the plants syringe them with petroleum and water at the rate of 3 ozs. to 4 gallons of water. This will do no harm to the buds or plants, but if very strong doses are used the effect may be visible about the time the blooms should expand. Later plants just completing their growth must be carefully treated, for in this stage they are liable to start again into growth. Give abundance of air and maintain a drier atmosphere until the buds commence to form, when the syringe may be used and the moisture in the atmosphere increased.

Azaleas.—Plants of narcissiflora, amœna, indica, and such varieties that have been forced into bloom early for several years past will be swelling their flower buds rapidly. Some of these are coming forward too quickly, and it will therefore be necessary to carefully harden them and place them outside in a northern position. They should have been out before now, but the wet weather would have proved serious to the well-being of these plants. Plants that are not too

forward should have a sunny position, their pots only needing protection from the burning rays of the sun. A northern position is only advised for the purpose of retarding them. While they are outside syringe them morning and evening when the weather is bright, and be careful that they do not suffer by an insufficiency of water at their roots. Those about to complete their growth should have abundance of air and as much light as possible, provided they are not exposed to such an extent that the sun will brown their foliage. Plants that flowered in May must be pushed on so that their growth can be brought to a standstill as early as possible.

THE BEE-KEEPER.

THE LESSON OF THE YEAR.

THE advantage of using large roomy hives capable of containing a good supply of food has been made more manifest than ever during the last two months. Those bee-keepers who in anticipation of the harvest contracted the broad nest in order to compel the bees to go into the supers have no doubt had time to repent at leisure. A body box crammed with bees and brood in every stage of growth, yet containing but a small quantity of honey, must have been an encouraging feature during the storms and rain of last June and July. The knowledge that stocks so treated are ever on the brink of starvation must have given zest to the bee-keeper's disappointment, and have filled his cup of sorrow to overflowing. Most people learn by experience, and if experience is a hard teacher her lessons are all the more perfectly taught and indelibly impressed upon her unwilling pupils.

The constant fidget and anxiety of knowing that a stock is short of food and yet crowded with bees, the inconvenience of having to remove supers in order to remedy this evil, and the consequent disturbance of the stock must be patent to all, and yet many bee-keepers reduce their stocks to poverty to induce them to work more zealously in supers. In fine warm weather such a course of management may partially succeed, but when cold, wet, and sunless days intervene before the supers contain any honey at all then the stock is in imminent danger, and the bee-keeper may well fear to lose—and richly does he merit the misfortune—all chance of a harvest. Such a fatal result may be prevented we know by timely feeding, but where is the common sense of making feeding necessary by taking away the food already provided? Yet this is constantly done.

How different the result when a little common sense and forethought are brought into play! Then we see a different system of management, and as a consequence a larger result. The man who uses a roomy hive and always keeps a good supply of food in reach of his bees has no cause to fear that a week's bad weather will ruin his stocks unless he renders them constant assistance. He knows that sufficient food is stored to guard against all normal bad weather, and may rest easy with the assurance that a few days' rain will not do much injury, and that even a longer period of inclement weather will not damage his prospect to any considerable extent. But it may be urged that bees in large hives are not so ready to work in supers. Is this so? Provided a stock is strong in numbers, and supers are placed at the proper time—before, that is to say, the stock has determined to send out a swarm, and yet not until the hive is crowded with bees—supers are readily taken possession of by the bees, and the work makes rapid and satisfactory progress. Of course when stocks are not really strong enough to enter supers, then by contracting the space in the body box, the bees are compelled to find a proportionate amount of room elsewhere, and consequently it is only necessary to contract the brood nest sufficiently to compel the bees to enter and remain in supers. Now for the result of such a masterly policy of activity. The laying space of the queen is diminished, therefore the number of bees reared in such a stock is limited; the queen cannot find room to deposit the eggs with which she is heavy, therefore the desire to swarm is engen-

dered; there is not sufficient room for brood alone, therefore every cell formerly taken up by honey is, when such honey is consumed, used for brood; the frames being filled with brood there is no food supply, and as a result a few days of bad weather endanger the well-being of the stock.

By using roomy hives all these evils are averted. The queen has sufficient space for the exercise of all her powers; no desire to swarm is therefore, under normal conditions, engendered. The stock continues to grow daily more populous, and the bees are encouraged to rear brood because there is a proper supply of food to encourage them, and supers are entered when the population of the hive is in excess of that which it is able to accommodate. Now, the swarming mania killed, a large population constantly increasing, and an absence of want give to the bee-keeper a much better prospect of surplus than starving stocklets artificially compelled to enter supers by the measures of a bee-keeper who calculates that by taking away space in the place a proportionate space must be afforded elsewhere to accommodate the population thus crowded into a smaller space than they have previously occupied with comfort. If this year of loss has taught the lesson which some bee-keepers decline to learn by looking at the experience of others such loss will not be without some gain.—FELIX.

TO CORRESPONDENTS

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Grapes (*Andromeda*).—When editorial letters are directed to the publisher in connection with matters of business some delay is inevitable in their delivery, the departments being distinct and conducted by separate staffs of officials. That is the reason your letter did not reach us till after the arrival of the Grapes last week; the reply, however, and reference we gave would meet your case. The collapse of Grapes, what is known as scalding, has been very prevalent this year.

Mushrooms (*Inquirer*).—The specimens you send are of the Horse Mushroom, *Agaricus arvensis*. They are safely eaten when gathered dry and in a fresh state, before the laminae or gills assume a dark or blackish colour, but lack the delicate flavour of the true meadow Mushroom, *Agaricus campestris*. They are freely used for making ketchup. Your letter arrived too late to be answered last week. This reply will be recognised, though your name is omitted.

Young Vines (*J. E.*).—We are glad to hear our advice has answered so well. The leading shoots we understand reach the top of the house. Some growers would let them run down the back wall, and further allow all the laterals that might push to grow unchecked to "encourage root action;" others, of which Mr. William Taylor, who grows Grapes so well, would top the growths and pinch succeeding laterals to a leaf as soon as their points could be seized with the finger and thumb. That is evidently Mr. Abbey's plan, as you may gather on reading an able article containing reasons for it on page 114.

Grapes Splitting (*Devonian*).—We have received the berries, and regret to say if you have no means of applying heat to dry the atmosphere that you are almost powerless to check the evil if dull wet weather continue. All you can do is to ventilate early and as fully as possible on all occasions when it would dissipate the moisture in the house, every part of which should be kept dry in your proverbially damp district. The cold and wet have prevented the fruit swelling outdoors, and injuriously affected the Lilliums. The season has been abnormal, and we must hope for better weather and results next year.

Under Gardener Leaving (*T. S.*).—The man who has given you a month's notice to leave, and informs you that he is legally entitled to

two half days in each week for the purpose of seeking other employment, and to be paid for that time, which is implied, is in error. No such right exists under the circumstances, and there is no custom generally recognised on which he could base such claim. Like yourself, many or most gardeners and employers would grant a man reasonable time for making personal application in the case of a known vacancy; but a right to a roving commission as suggested is visionary. The man is under a misapprehension, and has perhaps been misled, therefore may be excused for making a demand instead of asking a favour.

Arranging Pipes (H. H. C.).—Your question cannot be satisfactorily answered without particulars as to the position of the boiler, feed cistern, and length of pipes; indeed, a plan of the proposed arrangement drawn to scale is essential. It may be stated that as a rule a dip such as you mention impedes the circulation, and in all probability the water would flow more freely if the pipes were taken over the doorway; and if they were conducted just under the eaves of the house, so to say, and close to the base of the rafters, they would answer the purpose as well, and possibly better than placed along the ground or just above it. But wherever the pipes are, the bottom of the feed cistern should be on a level with the highest part of them, or they cannot be filled.

Answering Questions (A. McD.).—We assure you it is no "trouble" whatever to us to answer such questions as we are able to answer on gardening matters for our regular subscribers. The fact that you have only asked two, and in "both cases had to write again" before you received replies, is, to say the least, unfortunate. The last letter we received was answered promptly. There was no delay about that certainly, and the other event of four years is beyond our recollection. We have had many thousands of letters since then that have passed out of mind. It is almost a pleasure to be found fault with a little when you do it so generously, praising our work at the same time. We regret it is not in our power to prevent an occasional letter going astray.

Tomato Plants Flagging (H. F. S.).—Your general treatment, as described, appears to be good, so far, at least, as regards soil and watering; but we are not so sure the method of ventilation is all that it should be. When we are told the doors of houses are used as ventilators we always have a suspicion that there is room for improvement. The most successful cultivators do not make it a practice of leaving the doors of their houses open, though Tomatoes will endure this as well as most things. Do you open the top sashes early enough in the morning? They should be opened to some extent as soon as the sun shines on them. No amount of late ventilation can atone for the fault of leaving houses closed too long. Have you top-dressed the bed in which the plants are growing? If not, do so with rough turfy loam, surfacing with good short manure. This, kept moist, will incite the production of the "small white fibrous roots the plants lack." Constant applications of liquid manure are not conducive to the increase of such roots, and especially if rather too strong, as yours may be, though it looks weak. Try the top-dressing, giving water very copiously when the soil appears in the least dry, alternating with liquid manure, or giving it weaker. After much dull weather the leaves of most plants are liable to flag when the sun comes out suddenly and shines brightly, Cabbages in the garden being no exception. The absence of fibrous roots, with faulty and possibly too late morning ventilation, are, we suspect, the main causes of what you describe as the collapse of your plants.

Value of Prizes (F. Walker, Launceston).—When a prize is offered for the "most successful exhibitor" at a show in England, to be determined on the prizes won, it is customary, and we think fair, to allow three points of merit for first, two points for second, and one point for third prize, special prizes, when only one is offered in a class, ranking as firsts, and counting three for the purposes of adjudication. According to this exhibitor A in your contest must lose by five points, his total being thirty-one, that of B thirty-six. According to your method, in which it appears no third prizes were provided, the Judges and Committee were right, and according to the "English method" the defeat of A would appear to be still more conclusive; and if A had been B he would, perhaps, not have thought himself "wronged" if all the points of merit were credited to him to which he was entitled. In regard to Tomatoes, they can undoubtedly be grown cheaper in Tasmania than in England. The prices vary considerably. This year they are high, and fine fruits grown under glass are now selling at a shilling a pound in fruiterers' shops, but large consignments from southern Europe have been sold retail at from 2d. to 3d. a pound. Large quantities of canned Tomatoes come from America, and probably also Tomato sauce, but we do not think there are exact records of the extent of the importations. Tomato sauce is variable in quality and price. Tomatoes grow and ripen in fields in America as well as in Tasmania. Possibly your best method of acquiring the information you need will be by writing to such London firms as Messrs. Crosse & Blackwell, Soho Square, W.; R. Pink & Sons, 7, Eastcheap; and E. Lazenby & Sons 18, Trinity Street, Borough, S.E.

Mrs. Pearson Grape Failing (H. B.).—You appear to have waited till the last moment before sending the Grapes and letter, and thereby waited too long for receiving a reply last week. Every berry, again, arrived split and broken, we presume through shaking about in the tin box, for you would scarcely have enclosed a letter with fruit in such a wet state, and some of the writing is obliterated. You have perhaps not had much experience in sending soft fruit through the post, and it may be useful for you to know that it should be so packed as to be immovable in boxes. The leaves now sent show plainly that the

Vines are in a very enfeebled and unhealthy state, and the presence of roots on the rods suggest that those in the soil are defective. It is quite certain they are not supplying what the Vines need. How the evil has been brought about we have no means of knowing, possibly overcropping when the Vines were young, though you say nothing about their age nor the composition of the border. Your method of ventilation appears to be sound, and we have no fault to find with the temperatures. Unless a special desire exists to grow this variety we should uproot the Vines, for it will be a task of no small difficulty restoring their lost vigour. If they must be retained the fruit should be cut and the roots placed in fresh soil, cropping lightly, if at all, next year. Mrs. Pearson Vines usually grow freely, and there is something wrong with your soil or management. If you remove them the space can soon be filled with additional rods taken from other healthy Vines near without injuring these in the least under good cultivation. Possibly when the Vines were planted the canes were not sufficiently shortened, but borne too soon along their entire length. There is more we should have liked to know that you have omitted, but we can scarcely put questions and give answers too.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once. (*P. O., Chertsey*).—1, *Crinum amabile*. 2, *Clethra alnifolia*. 3, *Ophiopogon variegatum*. 4, *Kaulfussia amelloides*. 5, *Sansevieria zeylanica*. (*C. R., Cheshire*).—No numbers were attached to the specimens received, but those with blue, purple, pink, and white flowers are seedling varieties of *Centaurea Cyanus*; the others appear to be good varieties of *Chrysanthemum segetum*. (*R., Surrey*).—1, *Masdevallia Harryana*. 2, *Odontoglossum crispum*. 3, *Odontoglossum maculatum*. (*H. W.*).—*Salvia Sclarea*.

COVENT GARDEN MARKET.—AUGUST 22ND.

MARKET quiet, the soft fruit being nearly finished. Currants higher. Other fruit easier.

FEEDING MIXTURES AND MANURES.

PROTECTION from fraud in purchased food for animals of the farm, and in all fertilisers included under the comprehensive and popular term of artificial manures, is being sought more and more by farmers generally, and this sensible conduct is undoubtedly part and parcel of the wholesome economy enforced by hard times. Retrenchment in everything possible has been and is still going on, and among the waste and losses arising from ignorance and carelessness to which thorough-going reform is being applied, feeding cakes and mixed or prepared manures hold a leading place.

The Royal Agricultural Society of England, the Bath and West of England, and kindred societies all hold out a helping hand in this useful work by the facilities enjoyed by their members for having analyses made at a nominal cost by Dr. Voelcker and other chemists whose ability and character are altogether above suspicion. Full reports of this work are published periodically, and they certainly disclose a lamentable condition of things which have doubtless been long in existence, and which have tended in a remarkable degree to injure, and in many an instance to hasten the downfall of many a worthy farmer. Sweeping and unsparing is the condemnation of those firms who are thus shown to be trading upon the confidence reposed in them; but what is so very alarming is the well proved fact that it is quite the exception to meet with cake or manure which passes with impunity through the ordeal of the chemist's laboratory.

In the annual report for 1887 of the consulting chemist of the Royal Agricultural Society of England he wisely lays down that "there never was a time when farmers should more strongly insist upon having only pure cakes supplied to them, and make a point of getting a guarantee for the cakes being so. It is a frequent practice for a manufacturer or dealer to put forward an analysis giving merely the per-centage figures of the different constituents. But it must be remembered that it cannot be a matter of indifference whether what is stated in an analysis as 'oil' is *linseed* oil or some other of inferior value; and similarly whether the nitrogen and other elements arise from *linseed* or from some less valuable material. I would urge this necessity of insisting upon pure cake being used, inasmuch as so soon as admixture of any kind is admitted, there is no limit to its quality or its nature." He suggests that the requirements which a linseed cake should satisfy in order to be fairly termed a pure one are:—

- 1, That it be made from sound seed of not less than 95 per cent. purity, subsequently well screened.
- 2, That it contain no ingredients of a poisonous or deleterious nature.
- 3, That it be entirely free from sophistication of any kind.
- 4, That it contain not more than 2 per cent. of sand.
- 5, That it be sold in good merchantable condition.

As showing how largely aid is sought in this matter now we may mention the fact of 1615 samples being analysed in 1887, and the number will probably be still higher this year, as so many glaring examples of adulteration by firms of repute were detected. To quote a few examples we may take the following. Of linseed cake, "this is adulterated cake, containing quantities of locust bean, also cotton husk, and other foreign seeds, besides over 5 per cent. of sand." Of boiled bones, "this sample is adulterated with sulphate of lime (gypsum), and has over 2½ per cent. of salt." Of a patent carbon fertiliser for Oats, "a material not worth a sixth of what it costs." Then we are told of manure bought as dissolved bones which is not dissolved bones at all; of other

samples of cake containing an immense quantity of weed and other seeds, or which were impure and nasty, containing besides 4 per cent. of sand, cotton husk, niger seed, and other impurities.

Clearly, all this teaches that neither manufactured cake or manure should ever be bought without a guarantee of purity, and subject to analysis. Better still would it be to avoid such doubtful articles altogether. As our readers know we have done so for a considerable time, and prefer to select and mix our own manures, notwithstanding the labour, time, and care involved in doing so, for we have the satisfaction of knowing that we thus avoid all risk of loss from adulteration, and that the soil is rich in fertility. By careful management the use of cake may also be avoided, as much as possible home-grown corn and fodder should be used, and uncrushed linseed may enter largely into the dietary of our cattle. But for real fattening purposes we desire nothing better than a well balanced mixture of Beans, Oats, Barley, and Peas, either crushed or ground to meal. Of Oats we have such an abundant foreign supply at such low rates that is only under first-class culture we desire to use land for Oats at all.

WORK ON THE HOME FARM.

If the haymaking was at first tedious it became brisk and satisfactory enough towards the end, but for Clover, Sainfoin, and grass it extended over a period of nearly two months, and were therefore a tedious and costly process. We have some fine stacks; they are thatched and insured, and are therefore well off our hands for the moment. We must own to feeling some anxiety about rather heavy arrears of hoeing amongst root crops, especially in the later sowings of white Turnips. This is all the more serious because harvest is upon us and we shall have to manage as best we can by means of what extra labour can be had. This sounds like an outcome of bad management, but it only exists at two of our farms where the haymaking was exceptionally heavy, and we may add that with several hundred of acres of hay to save in a wet season, the most well-considered plans are liable to be upset.

Peas, Oats, Rye, and Wheat are the corn crops now ready for and being mown. The rate of pay is from £7 to £8 per man, and the average acreage is about thirteen per man, including the reaping, binding, carting, and stacking. We shall use no self-binders this season, for so much of the best Barley is beaten down that binding is out of the question, and the actual reaping will prove by no means an easy matter. Many Oats and Peas are already in stack, and on light land Wheat follows closely. There is much difference in the Wheat crop this season, much of the late sown Wheat being still quite green, but we are glad to find anything like blight or disease is the exception and not the rule this season. Our chief anxiety in connection with the harvest is about the Barley. The grain is so far excellent if only we can save it without much exposure to heavy rain, so as to ensure quality in combination with quantity. The outlook for both green fodder and hay next season is excellent; never were young Clover and other layers more luxuriant or a fuller plant, and we appreciate this success all the more from the very general failure of layers last season. Owing to this failure both Clover, hay, and home grown seed will be scarce, and it is probable that very few old layers will be left over till spring. We are folding sheep upon them, and ploughs follow in preparation of the soil for Wheat sowing.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

12th.—Fair, but generally overcast except for an hour or two at midday.

13th.—Spots of rain early; bright day with strong wind.

14th.—Bright and fresh.

15th.—Overcast morning; fair afternoon, with a little sunshine, but cool throughout.

16th.—Bright early; cool and generally cloudy day.

17th.—Overcast and cold throughout.

18th.—Dull morning and fair afternoon, but cool.

A rainless week following a dry one. Temperature lower, and weather generally dull.—G. J. SIMONS.

VINES IN POTS.

WHATEVER may be urged in favour of "cut-backs" for early forcing (that is, canes of moderate size, or those suitable for planting) or the reverse, it cannot be questioned that firm, stout, well-ripened canes can be produced in one season from eyes. The system of using cut-backs for this purpose in many establishments is practically obsolete. Keen competition and principles of economy have had much to do with this, for all must admit it is needless to grow a plant two years if the same results can be achieved in one. Good canes that will fruit freely can be produced in one, but they bear no comparison for early forcing with those that are the result of two years' growth. But the growth and treatment of the two, while in some respects they are the same, must in others be totally dissimilar. This assertion will, I think, be largely borne out by the practice of those who have to force them and produce the fruit in a ripe condition. Those grown from eyes are suitable for forcing after Christmas, and for that period of the year are equally as good as two-year-old canes, but for the production of ripe fruit by the first week in May they are not suitable. It may be necessary for comparison to trace briefly the two systems of culture.

Cut-backs, such as I have described, have in some establishments given place to a much smaller kind of cane for the purpose. These are the latest of those raised from eyes, and are only shifted once from the pot in which the eyes were started. As a rule they are accorded a makeshift place, and finally grown under the shade of those intended for fruiters. This is not always the case, but they usually have second-rate positions. They are allowed to attain from 15 inches to 2 feet in height, and are then pinched as many times during the season as requisite to keep them in that condition. Young Vines of this description are preferable to cutting back planting canes only from one point of view, and that is because they do not entail the same labour or take up the same amount of space. I have never viewed these stunted youngsters in a favourable light. Grown in the shade and confined at their roots, they cannot possibly be in the most satisfactory condition for growing vigorously the following season. The principle of pinching them is right, provided they were placed in 8, instead of 6-inch or smaller pots, and grown and ripened under the influence of full light and sunshine. Such Vines would be much better than the ordinary cane grown 6 or 7 feet in length and then pinched. The latter concentrates its energies in the production of plump buds and wood at the top, while the other thickens at the base and has bold buds from which to start the following season. Canes grown either from cut-backs or these small Vines are no better for the production of canes for early forcing if they are only pushed along side by side with those that are grown from eyes. By February they should have 2 to 3 feet of growth, and from that time extend rapidly until the desired length has been attained, and then stopped. By the middle of May they will have developed almost to their full size and the work of solidity be well advanced. However good the treatment of those from eyes may be, they cannot attain this condition for at least three months later. The one by that time is thoroughly matured, the other has to mature. Which, then, is the best for early forcing, a cut-back well and properly grown, or one from an eye? There is no comparison, for the first has enjoyed a good season of repose before the other loses its foliage, if that is cared for in its last stages. If Vines raised in a season are used

for early forcing, the foliage is removed prematurely, they are robbed of a season of rest; refusing to start into growth by gentle means, it must be forced out of them, and Vines subjected to such treatment seldom perfect their crop of fruit.

Cutting back canes of the ordinary planting stamp is not regarded with much favour, because, as a rule, they rarely make such good canes as those grown from eyes. Under any circumstances they are the thickest at the base, but do not attain the same size and strength at the top. Three reasons may be adduced why cut-backs do not succeed as well as those raised from eyes, due entirely to the system of culture accorded them during their latter stages of growth and the method of potting adopted. For some years it has been the practice to turn Vines outside in full leaf during September after the canes have turned brown. Early frosts would destroy the whole of the foliage in a night. Sudden or untimely destruction of the foliage means destruction to the greater part, if not the whole, of the fibry roots. They are in an immature state, and must naturally perish as well as the leaves. The practice of turning out Vines may be more successful in the southern parts of the country than in the north; but the system has extended to the north. It is an uncertain plan, and the risk is great anywhere. The foliage should be preserved as long as possible—that is, all the main leaves, until they naturally present an autumnal appearance. Towards the end of August, or at the latest by the middle of the following month, when the temperature in which they are growing is considerably lowered, remove all the laterals, so that the energies of the plant can be concentrated in storing food for future use and the full development of the buds. Leaving the laterals on until the foliage ripens is only a waste of material. Who would think of destroying the whole of the foliage in a late vinery directly the fruit was ripe? To do so would be regarded as madness. A pot Vine raised from an eye is in exactly the same condition, and yet they are too frequently subjected to such barbarous treatment, and are then expected to fruit or do well another season when they are cut back. I have dealt rather more fully with this part of the subject than I intended, as it is of such importance that it is necessary to impress upon those who grow Vines for sale the desirability of providing shelter for them in their last stages of development.

The third reason is due to the system of potting. If we suppose those to be cut back have matured their foliage and roots, considerable quantities of the latter are destroyed by disentangling them and shaking away the whole of the old compost. This is a serious check to the Vines, and one, if not the main reason, why cut-backs do not give satisfaction the second season. For years I have failed to see what advantages could follow such a severe system of root-pruning. If we dig up an Apple or Pear tree we do not expect it to grow with the same vigour the following season, and why should the Vine be an exception to this rule? When the Vines are to be fruited and then thrown out there is not the slightest occasion for shaking them out when repotting them. If the roots would not take kindly to the new compost then the case would be different, but when potted the roots take possession of the new soil with as much freedom as those of any other plant. If well-ripened canes are wanted from cut-backs they must be started into growth early on the same principles as established Vines, and not plunged in strong bottom heat to force root activity before the top growth is sufficiently advanced. This is too often done in the hope of assisting Nature, and thus gain greater achievements, while the very opposite results.

I have repeatedly proved that cut-backs can be grown into stronger canes when they are potted with the ball of soil intact, merely removing the old drainage, surface soil, and a little round the top of the ball, than can be accomplished by shaking the whole of the soil from them. Cut-backs of this description and strong fruiting canes as well potted will fill their pots with roots during the season. When the Vines are repotted does not matter in the

least; it may be done just as they are breaking into growth or while they are in a dormant state.

I cannot help thinking that with permanent Vines no advantage results from following the orthodox principle of shaking away the soil and spreading out the roots. Canes planted on this principle certainly do not make such a rapid growth the first season as those that are planted without disturbing the roots. For a time, it is true, that the greater care is needed in watering by the latter method, but they soon root out in all directions, and are practically independent of the old ball. If they are in a moist state at planting time, and the soil pressed firmly about them, there is no difficulty in keeping them in that condition.—W. B.

GLADIOLI.

THERE was in the early part of the year a little controversy about this charming, though fickle, daughter of Flora, and it is a question whether the present season does not add considerably to the character of fickleness in this autumn beauty. One of the points under discussion was the means of inducing late varieties to flower in any season in the north, and in seasons like the present to have more than a few to flower, with the no less important matter of maturing the corms. It may be remembered that I advocated starting the plants in much the same way, and for the same reason, that Potatoes are sprouted. I had some experience of the utility of this process, and again did myself this year what I had advised others to do. The results may be somewhat interesting, and I propose to send a few notes as to the times of flowering of the varieties, appending to this note a list of those now in flower in this the worst season. Some folk will have it that we have never had a worse since 1879, when very few Gladiolus flowered in this district. The plants, it may be noted, were much crippled by the cold easterly frost which did such harm in early June, the tips of the leaves of many plants having been killed, and the foliage then expanded, as a whole, much damaged. All those noted were started in boxes and planted out with good roots in the end of April.

Gandavensis hybrids in flower:—2 Horace Vernet; a fine sort. 1 Carnation. 2 Amiral Courbet; a pleasing bright purplish-rose variety. 3 Arsinoë. 3 Amalthée. 1 Penelope; soft pleasing colour. 1 Dumont d'Urville. 4 Caprice; very beautiful shell-like petals. 9 Shakespeare; a most useful sort. 1 Panorama. 1 Diamant; a flimsy but lovely flower. 1 Orphée; very good. 1 Albion; a good light variety. 1 Archduchess Marie Christine. 1 Opale; a lovely light sort. 2 M. A. Brongniart; one of the very best.

Of Lemoine's hybrids I have only about sixty plants, of these the following are flowering:—2 Lemoinei; very beautiful. 1 Etoile; much the same shades as above, but quite distinct; fine. 2 Mons. G. Henry; a bright-coloured variety. 1 President Grévy; a lovely flower. 4 Lafayette; very large, 4 inches across the flowers, looks somewhat like Shakespeare with a dash of yellow suffusing the white; very good. 1 Lamartine; as large as the above, and of a pleasing and peculiar shade.—B., *East Lothian*, August 24th.

ARTIFICIAL MANURES.

THE enlightened state of your correspondent, Mr. H. Dunkin, is to me a matter of considerable satisfaction; not that I wish to take credit for all the truths that have at last dawned on the controversial horizon of my doughty opponent, but rather let me compliment him on his diligent research amongst scientific authorities, and the interesting and useful facts he has brought forward in the vigorous defence of his views.

Now that the favourable turn of opinion in regard to "combinations" is given in such a candid manner by Mr. Dunkin, I cannot but admire the ingenious way in which he makes the admission. "Judicious combinations" he has discovered in the tenor of my arguments, and yet "properly proportioned combinations" he formerly used as a target for his sarcastic shaft. Where the delicate line of demarcation comes in would, I think, be difficult to decide; whether we call the system we follow by one name or the other, whether it be in the compounding of a perfect plant food, or in the manipulation of the powers we use to attain the object of our desires, the search after perfection will, I still contend, be conducted on these lines.

Artificial manures are even now, in the majority of instances, clumsy compounds, and their application even worse, although a vast improvement is taking place in the host of new plant foods that annually appear, and also in their application at the hands of many cultivators. A good general knowledge of plant life and the science of its support seems to be more general. Not only does the science of plant foods benefit the horticulturist, but to the agriculturist the "knowledge is

power," especially in these times of keen competition; and though much has been said and written in derision of the scientific farmer, I am firmly of opinion that he will, with the scientific gardener, pursue his calling to a pecuniary successful issue.

Nothing now remains for me but to thank my ex-opponent for the deep consideration he has given to the questions at issue, and I hope at some future time we may again have the pleasure of crossing a friendly pen. Meanwhile I leave him to continue his scientific studies in peace, and if his efforts should possibly produce a perfect plant food, I will do my best to accord him all the honour due.

To the Editor I tender my thanks for space allowed, and a general apology to long-suffering readers, some of whom are no doubt glad to see this somewhat tedious controversy draw to a close.—M. COOMBE, *Ashton Court Gardens, Bristol*.

CABBAGES FOR SPRING.

IT is very important to have Cabbage in as early as possible in spring as other vegetables are often scarce at that time, and any addition is valuable. I find that Cabbages are not thought much of during the summer, but as soon as the frost cuts down such tender vegetables as Beans, Cabbage are in request, as also are Savoys. I like to have a good breadth of Coleworts ready. Rosette Calewort, Sutton's Little Gem, and Ellam's Early are sown during the last week in May, and sometimes the first week in June. These have never failed to give me plenty of good heads during November and December, and although I have often had some left until the spring, they have all bolted then, and had to be used as greens.

For spring Cabbage I always sow about the 10th, and again about the 20th of July. In 1886 Ellam's Early, sown about the 10th, nearly all bolted in the following spring, and the small plants from the late sowing gave us the best Cabbage in 1887; and yet the same variety, sown at the same date last year, hearted in this spring without one bolting. It would certainly not do to depend entirely on seed sown here (midlands) as early as the 10th of July of the small early sorts. I always prick my plants out in a nursery bed as soon as they have two leaves beside the seed leaves. They are generally ready to plant about the first or second week in September. I do not think we always know the cause of bolting. I believe it is sometimes caused by bad strains of seed, sometimes by the mild weather during winter followed by a very sharp frost, and mild weather coming again suddenly, then if the plants are large they will often bolt. Sometimes it is caused by sowing the seed thick and letting the plants stand in the bed too long, and then planting them in loose rich soil.

As to varieties, I think no one should condemn a variety until he is sure he has the true one. I find that some seedsmen do not send all varieties out true, they generally send out their own particular sorts true, and these can be depended on; they have each their improved strains to which they wish their customers to give the preference. I think I have tried nearly all the varieties of Cabbages, and I find Myatt's Offenham the best for spring. With me it is as early as Ellam's, and has much larger heads, with very little outer leaves. I grew Early York at two or three different times, but it was not so good as some other varieties.—J. L. B.

[We have a reply from "A Kitchen Gardener" to "A Yorkshire Cabbage Grower." It is short and sweet, but cannot be inserted this week.]

ROYAL HORTICULTURAL SOCIETY, CHISWICK.

FRUIT AND VEGETABLE COMMITTEE.—A meeting of this Committee was held on the 21st inst. at Chiswick. Present—Mr. W. Warren, in the chair; Messrs. Howe, Cheal, Barr, Denning, Smith, Wright, Marshall, and Cummins. The following crops on trial this season were inspected:—

1, *Potatoes*.—A collection of eighty-six varieties being grown. With very few exceptions they were found to have suffered severely from the disease, the early varieties more especially so. The following varieties proving to be good croppers and of fine appearance were subjected to the test of cooking—viz.: Governor (Dean), Lavington Conqueror (Lye), Epicure's Delight (Smith), Vegetarian (Dean), Renown (Webb & Son), Dêbûtante (Ellington), Castle Morton (Collins), Nelly Blue Eyes (Dean), Basford Beauty (Howard), Bluebeard (Dean), Purple Beauty (Dean), Stirling Castle (Murdoch). None of them was considered of superior quality, being somewhat watery, a result attributable to the excessively wet season.

2, *Cabbages, spring sown*.—A collection of forty varieties. The following were selected as the most desirable varieties to cultivate for use at this season—viz., Early Etampes (Vilmorin), Early Paris Market (Vilmorin), Leeds Market (Rutley & Silverlock), Prince's Nonpareil, Early Dwarf York.

3, *Tomatoes*.—A collection of fifty-two varieties grown in pots. None of these were considered superior to sorts certificated in 1887, and now in general cultivation.

FLORAL COMMITTEE.—A meeting of this Committee was held on the 24th inst. Mr. H. Herbst in the chair. Present—Messrs. Walker, Dean, Laing, Noble, Goldring, Masters, Lowe, Hibberd, Rollett, Bates, Dominy, Fraser.

The collections of Stocks and Asters on trial in the gardens were examined. Of the large-flowering Ten-week Stock from Messrs. Vilmorin the following colours were selected as the most distinct, and awarded three marks—viz., white, sulphur, lilac, blood red, violet, light violet. Of the same section from Messrs. Benary the white, dwarf

white, brick red, and light blue received three marks; also of the Dwarf German Chamois and those of the new Giant Perfection (Benary), sulphur yellow and light blue, received three marks, and the dark blood red from the Novelty Company.

Amongst the Asters the following received three marks. Half dwarf: Multiflora, white; ditto, light yellow (Vilmorin); Globe Paouy-flowered, copper coloured, white edge (Vilmorin). Dwarf: Chrysanthemum, rose (Vilmorin); and ditto, scarlet red (Vilmorin); Dwarf Queen, crimson (Benary); Dwarf Queen, white (Benary); Mignon (Benary). Pyramidal: Hedgehog or Needle, dark crimson (Benary); large flowered rose, dark scarlet (Benary); Triumph (Novelty Company). The following assortments of various colours from Benary were commended—viz., double dwarf, early flowering, fourteen vars.; dwarf bouquet flowered (Boltzes), eight vars.; dwarf Chrysanthemum flowered, ten vars.; dwarf pyramidal flowered, twelve vars. The later varieties will be further examined.

THE COLD STORAGE OF FRUIT.

It will be remembered that the Royal Horticultural Society, desirous of ascertaining the practicability of preserving soft fruits under the influence of cold, appointed a Committee to conduct experiments in co-operation with Mr. D. Tallerman of the Leadenhall Cold Storage Company, whose cold chambers were obligingly granted for the purpose in question. The Committee met on Thursday last at the Company's offices in Gracechurch Street, T. Francis Rivers, Esq., in the chair. They had both a warm and a cold reception, for it was necessary to linger in the engine house in a temperature of 90° or more till preparations could be made for further progress, and then pass into very snowy surroundings. It was a change from the torrid to the frigid zone in a moment, and not an experience for persons in delicate health. The cold in the three rooms was reduced by steam to about 36°, 25°, and 22°. Several half-bushel baskets of Cherries were placed in the chambers on August 8th, wet, and some of them decayed. Some were frozen like marbles, others were abnormally firm, but not actually frozen, others remaining soft. Those that were not frozen were in the same condition as when stored fifteen days previously, and those that were decayed then had not in the slightest degree communicated decay to others pressing against them. Those in the coldest freezing chamber were spoiled. Soft fruits must evidently not be frozen, and the point to determine is the amount of cold that suffices to arrest fermentation, and this settled, it is not unlikely that soft fruit can be kept for some weeks or months. Various kinds of fruit will be tried under differing conditions in the hope of acquiring information of substantial value.

NORTH AMERICAN ORCHIDS.

Most of the Orchids indigenous to the United States of North America are hardy in this country, and several of the Cypripediums constitute the most showy of the Orchids grown out of doors here. A writer contributes an interesting article on the plants to "Vick's Magazine," and from this we take the following notes:—

The Showy Orchis, considered by late botanists our only true Orchis, and Putty-root, are known to me only by reputation. Orchis grandiflora and O. orbiculata, the Habenaria or Platanthera fimbriata and P. orbiculata, of Gray, are likewise strangers. Cypripedium acaule was a friend of my Massachusetts school days, growing in the edges of Pine woods, but I have never found it here, perhaps because there are no Pine woods. Careful search in a swampy woodland was rewarded with Cypripedium pubescens and C. parviflorum, much alike in general appearance; the latter smaller, with deep yellow fragrant flowers, while those of C. pubescens are scentless.

In late summer a patient tramp through bush and briar in the same woods may be rewarded with the lilac spray of Habenaria pycnoides, the smaller Purple-fringed Orchis, an exceedingly beautiful plant, which has a provoking trick of disappearing from its home when that has been discovered. I have found it growing in its delicate beauty, plucked the flower stem carefully not to injure stalk or root, taken the bearings of trees and under-shrubs, returning the next summer to search for rods around in vain. It had disappeared as completely as the Tulip bulbs I used to plant in the garden in the fall did by spring. The blame in the latter case was laid to ground moles. Did some ground mole or field mouse serve Orchis roots as a dainty at some winter festival?

The Ragged Orchis, Habenaria lacerata, with yellowish-green flowers, is not unlike H. pycnoides in appearance of plant, though quite inconspicuous as to blossom. But to a victim of the Orchid mania beauty of colouring is not an essential feature of a plant's claim to regard. We admire it for its grotesqueness, its curious arrangement of parts, because it is unlike anything else—in short,

because it is an Orchid. This Ragged Orchid I have found without very much trouble in wet meadows and pastures in late summer. The "intervalles," or hollows in the wet meadows that are skipped in the mowing, are often treasure gardens of flowers in late summer. The mowing cuts off so many stems before they bloom; some send up a feeble growth and a few flowers later, many give up the attempt for the season.

In similar places grows *Spiranthes cernua*, which is plentiful enough to gather by handfuls, the only Orchidaceous plant I am inclined to call common, from my experience, unless I except *Goodyera pubescens*, though on some hillsides and in hedgerows *Spiranthes gracilis* is not rare. Both are called Lady's Tresses. The most noticeable difference between them is that the flowers in *S. cernua* are in three ranks or rows on the spike, while those of *S. gracilis* are in one spirally twisted row. The leaves of *S. gracilis* commonly wither away before the flowers open, leaving the prim little stalk standing stiff as if in a child's play garden, where the flowers are but blossoms pulled and stuck in the earth.

One of the handsomest of our members of "the royal family" is *Calopogon pulchellus*. It scarcely has a common name. Wood mentions "Grass Pink," but that is misleading, and is frequently applied to a far different plant. I first met it on a warm day of early summer, the pink-purple blossoms seeming to float in the air as the wind swayed their delicate grass-like stems. A certain bog pasture supplied these floral butterflies for some years with tolerable regularity, but for some years past I have failed to find them. It may be I did not time my visit aright, and hours of careful search when not in bloom would hardly reveal their slender stems amid the lush growth of midsummer.

Among my relics of school days is a pressed plant of *Pogonia ophioglossoides*, earlier and paler than *Calopogon*, which it yet resembles considerably. I found it then in a moist hollow in an old pasture, but a patient search in similar spots in this locality has never been thus rewarded.

Goodyera pubescens and *Corallorhiza* are not infrequent in the woods where the Yellow Lady's Slipper grows. The leaves of *Goodyera* are so peculiar that the plant can be easily recognised at any season of the year. It is the most conspicuous of our plants with mottled foliage. The nearest approach to it that I know of is *Hieracium venosum*, Rattlesnake Weed, often seen in our woods and hillsides. That has root-leaves veined and mottled with purple, but it has not the exquisite lace-like appearance of *Goodyera*. *Corallorhiza multiflora* is the only species of Coral-root I know of in this section, but they are much alike. The writer of the article published in January wonders why most plants destitute of green herbage wait for the late summer. If they are, as generally supposed parasites, fastening their roots to those of other plants, and drawing thence the nourishment for their strange growth, it may be a provision of Nature in order that the nurse plant may not have the drain on its vitality till its own season of most rapid growth is past. I do not wish to say that such is the solution; some of the Broomrapes flower in spring, but the trees on whose roots they appear to feed are not likely to feel the loss of sap enough to support such pigmy dependents. The only one of these "royal" neighbours I have ever attempted to domesticate is *Goodyera pubescens*. It failed to survive the winter, perhaps for lack of the warm coverlet of leaves the autumn wind tucks so neatly over it in the hollows of its native woods.

CONFERENCE OF FRUIT GROWERS AT THE CRYSTAL PALACE.

A MEETING of the Executive Committee of the above Conference was held in "Anderton's Hotel," Fleet Street, on Tuesday last, August 28th, T. Francis Rivers, Esq., in the chair. The principal business was the consideration of a number of communications received by the Hon. Secretaries, Messrs. Lewis Castle and Wm. Earley, offering papers and suggestions, and the determination of the programme for the Conference. The Committee now comprises about seventy of the leading fruit growers, nurserymen, and amateurs throughout the kingdom, all of whom had expressed their hearty approval of the scheme, and their desire to assist in rendering the meeting both useful and interesting. After considerable discussion it was decided that the subjects should be taken in the following order, each paper to occupy about twenty minutes in reading to allow ample time for discussion. The Conference will be held in the Crystal Palace (the place will be notified on the morning of each day) on September 7th at 3 P.M., and September 8th at 2 P.M. On September 7th the first subject will be "Fruit Culture for Profit," by Francis T. Rivers, Esq., to be followed by Mr. Coleman, Eastnor Castle Gardens, and others. The second subject will be "The Packing, Carriage, and Marketing of Fruits," by Mr. Webber of Covent Garden and Mr. Samuel Rawson of Birmingham. On September 8th Mr. Tallerman will deal with "Fruit Distribution," Mr. Manning with "Fruit as Food," and Mr. Albert Bath with "Land Tenure in Relation to Fruit Cultivation." All who intend taking part

in the discussion will facilitate the arrangements if they send in their names to the Hon. Secs., Mr. Lewis Castle, South Wimbledon; Mr. Wm. Earley, Ilford; or to the Chairman on the day of the meeting.

CULTURE OF EUCHARISES.

THE Eucharis plants here have been subject to the disease for some time. No special experiment was tried to eradicate it, only what I should call careful treatment. To commence with, all the plants early in January were turned out of their pots, and the bulbs were dipped into Fir-tree oil. A selection was then made, placing all the large bulbs together, and these and the small ones being potted separately. The compost given consisted of good fibrous loam, the soil being well shaken out, a liberal dash of coarse sand, charcoal, and soot. Pots 12 inches in diameter were employed, carefully drained about one-third of their depth, putting about a dozen large bulbs in a pot, the small ones more; these were potted firmly, taking care not to bruise the bulbs.

After potting a little bottom heat was necessary to assist them

and plants preserved in winter or forced in early spring. All we can do in such a case is to give our friends a choice of three plans—a lean-to pit, a half span, and a full span, leaving them to select the one that may be deemed the most suitable.

Fig. 20, prepared by Mr. E. Luckhurst, shows sections of three houses: A, a snug little lean-to—propagating, Melon, or Cucumber house. B, a semi-span, possessing all the advantages of A, with the important additional one of a stage for stove plants and Orchids; or it could be turned to account for a variety of useful purposes, especially the early forcing of Roses, flowering shrubs, such as Deutzias, Weigelas, Lilacs, as well as Lily of the Valley and bulbs, or for wintering bedding plants. This house would also answer admirably for Vines in pots and Kidney Beans. C Shows a section of a loftier elevation—a lean-to, forming the most simple style of vinery as well as the most efficient. Sweep away all internal fittings—the stage, the inner wall, the soil and rubble; put plenty of pipes near the floor, not on it, but just elevated a few inches upon pipe stands, so as to turn all the heat to account and let none of it be wasted by absorption into walls and floors, as is too often the case; pierce the front wall and plant Vines in the soil, and we do not see what more a skilful Vine-grower would require, or what advantage a more elaborate state of

FIG. 20.—COMBINED SECTION OF PROPAGATING PIT, MELON HOUSE, AND VINERY.

to make fresh roots and growth. A little fermenting material was placed in the Cucumber house, in which the plants were plunged when the temperature decreased to about 90°. In this position they remained for about ten weeks, attention being paid to the shading and the supply of tepid water. When removed they were not shifted directly from the plunging material, but the pots were lifted, the bed levelled, and then replaced so as not to give any check after the strong bottom heat, but gradually hardening the plants to the house temperature; from this they were taken to the stove.

The system of resting that is greatly practised in many places is to remove the plants from the house where growing to a lower temperature, keeping them dry for five or six weeks. I have seen plants lose their roots and fall into ill health through this practice. Here the plants remain in the same temperature as when growing, keeping them dry for a month or so, but never allowing the soil to become dust dry. The culture as mentioned has proved most satisfactory, some of the plants being now 4 feet in diameter and carrying nine and ten large spikes of flowers, few traces of disease being left.—FOREMAN, *Besborough, Cork*.

PITS FOR MELONS.

Two correspondents write to us on the same subject, but neither of them appears to know exactly what he wants; one plainly indicates that he does not, and the other simply asks for a plan of a Melon house without saying anything about its shape, whether span-roofed or lean-to. Pits appear to be coveted in which Melons can be grown in summer

things would confer upon a non-skilful one. Leaving, however, the vinery out of the question, the semi-span roofed pit would be excellent for Melons.

We now reproduce a pit from a plan of Mr. R. Inglis (fig. 21), and cite his remarks thereon:—

"In the erection of pits, the conservation of heat by the means of 'mother earth' is very often under-estimated, if not ignored altogether. I think there is nothing we can do with more advantage to our plants than endeavour to have them rather under ground than above it. The further a house or pit is raised above ground the more it catches the bitter blast in winter. The roof we must have exposed; but why have the walls also exposed, when they can be built for less money, and heated at less cost afterwards, by having nothing exposed to the elements but the glass roof? And not only is it of advantage in heating in winter, but it is of great advantage in the maintenance of more genial moist atmosphere in hot dry weather in summer, as everyone can testify who has had experience of such pits, or given the thing serious consideration. For a range of useful pits I would suggest something like what is represented in the accompanying section. Supposing *a a* to be the ground line, mark off and level the soil where the outside walls are to be, and run it hard so that there is no chance of its sinking. On this build your outside walls, placing at intervals of 6 or 8 feet under the wall a right-angle elbow 3-inch sanitary pipe, socket end up, as shown at *b b*. By placing three bricks on edge round its end and breaking off the end of the brick just above this pipe, a connection with the inside of the pit is secured. Another pipe, placed in the socket at *b*, will rise above the eaves of the pit; and to prevent wet entering, a tin or zinc cover can be supported 3 inches above the pipe by three pieces of stout wire, to fit inside the sockets. These will form ven-

tilators which may in most cases be left open, except in severe weather; but when desirable to have them at command, a small shutter to each inside can easily be applied. When the mortar is sufficiently set, the spaces between the walls *d d* and also *e e* may be filled up with the soil excavated for a footpath *c*, building a wall on each side in the usual way. The space between the pits should be in the form of a gutter, asphalted, and made to carry the water to tanks inside the pits. These gutters should be 18 inches or 2 feet wide, and if the ventilators are placed alternately there will be plenty of room for cleaning out, attending to shading in summer, or applying mats or other coverings in the winter. A drain-pipe under the ashes in the beds will carry part of the water (otherwise wasted) back to the tanks. The inside arrangement of this pit is specially adapted to the growing of decorative plants of dwarf growth, such as *Cyclamens*, *Primulas*, *Cinerarias*, *Bouvardias*, *Achimenes*, *Begonias*, *Poinsettias*, and dozens of other plants, which will do far better than in houses of any other description. But with a little modification of the arrangements it can be made equally suitable for propagating, forcing winter-flowering plants, growing pot Vines, Melons, Cucumbers, Tomatoes, &c.

"The great objection to these sunken pits is the necessity of having steps down to the doorways. This, however, is not always necessary. If they are built on sloping ground they may be so arranged as to be wholly under ground, except the ends in which the doors are placed. In such a case the end walls would have to be built first, the mean height of the soil ascertained and levelled in the same way as you would form a terrace, and upon this level, properly consolidated, commence to build as on level ground. In building a number of such pits a large tank should occupy the opposite end to the door, and these should not only be connected with each other, but should be made one tank, so that the water will run direct from the gutter into it. In every such tank a flow-and-return hot-water pipe should be placed, for the use of cold

FIG. 21.

water in watering plants works untold mischief wherever it is applied in heated structures."

For growing early Melons and Cucumbers it would be desirable to make larger excavations at *e e*, down to the floor line, providing two pipes for bottom heat as in fig. 20, in rubble, with soil above them for the plants. With sliding shutters in the wall any excess of bottom heat might pass into the house or pit, then two pipes instead of three would suffice for top heat, in a sunk pit of the kind shown, 8 feet from the floor to the ridge, and 10 feet wide. Top ventilation should be provided as in the preceding plan, fig. 20; in the sunk pit the bottom ventilation is admirably devised, as the cold outside air in spring must be warmed before it reaches the plants.

POISONED BY BUTTERCUPS.

A CORRESPONDENT sends the following note clipped from a daily paper, and desires further information respecting the poisonous properties of Buttercups:—"Farmers in Bedfordshire are at present feeling considerable anxiety in consequence of several horses and other animals having died in a manner which suggests the belief that they have been poisoned through eating some noxious plant. Two horses belonging to Mr. Wm. Gray of Mill Street, Gamlingay, which were grazing in a meadow on the farm, were suddenly taken ill, and both succumbed in a very short time. A veterinary surgeon on examining the bodies found that where some partially digested food lay the coating of the stomach was covered with blisters as if from the effect of some vegetable irritant. Two valuable cows were also lost from Warsley Park, it is supposed from a similar cause. Suspicion attached to a variety of Crowfoot which during the late rains has largely increased in growth in boggy parts of the meadows. Several specimens of this plant were forwarded to the Botanical Secretary of the Bedfordshire Natural History Society (Mr. J. Hamson), who has come to the conclusion that the plant which has poisoned the animals is the Lesser Spearwort (*Ranunculus flammula*), a very poisonous variety of Crowfoot. It is rather uncommon, but the wet season seems to have been favourable to its development."

The appended particulars are given in Dr. Hogg's "Vegetable Kingdom" concerning the active qualities of the British species of *Ranunculus*:—"Of the *Ranunculeæ*, *R. bulbosus*, *acris*, *sceleratus*, *flammula*, *auricomus*, *thora*, *arvensis*, and many others, have very powerful acrid properties; and their fruits, when green, appear to be the parts in which this acidity is most intense. If the fresh-bruised leaves are applied to any part of the body a more or less active inflammation will soon appear, followed with hard swellings, which will speedily become a true blister. Recourse may therefore be had to these plants, as is the case in Norway and the Highlands of Scotland when cantharides cannot be obtained, or when the irritant action of these on tender plants would be injurious. Taken internally, the juice or extract of *Ranunculus acris* causes an intense inflammation of the digestive organs, and if the dose has been considerable it is a true acrid poison followed by very serious results, and even death. The juice of *R. bulbosus*, applied to the nostrils causes sneezing, and a portion of the root has been found to act beneficially on the gum of an aching tooth. Haller informs us that the Swiss hunters chew *R. alpestris* as a restorative after fatigue, and as an antidote to giddiness; and Withering states that in the case of poison having been taken, *R. flammula*, which produces instantaneous vomiting, is preferable to any medicine. With the juice of *R. thora* the Swiss hunters were wont formerly to poison their darts, by means of which the wounds inflicted on wild beasts were speedily fatal and incurable. The distilled water of *R. sceleratus* is eminently acrid, and when cold deposits crystals, which have been found to be utterly insoluble, and of an inflammable nature; yet, notwithstanding its poisonous properties, it is eaten when cooked by the shepherds of Wallachia. *R. aquatilis* forms an exception to all just mentioned, having been found to be not only innoxious, but nutritious to cattle. Dr. Pulteney says that in the neighbourhood of Kingswood, on the borders of the Avon, cottagers support their cattle almost entirely on this plant. They collect a quantity every morning, and bring it in a boat to the edge of the water, where the cows eat it with great avidity. One man kept four cows and one horse so much upon it that they had not consumed more than half a ton of hay throughout the whole year. There is no doubt that the continued immersion in the water is the cause, as we have already stated, of the destruction of the acrid principle in this plant. *R. repens*, or Buttercup, has less of the acrid quality than most of the genus, and is said to be eaten as a potherb. Cattle, however, do not feed on it willingly, and yet in many grass fields it makes a considerable part of the pasturage. *Ficaria ranunculoides* is also less acrid than some of the others; but although its leaves are used as a potherb when cooked, yet its roots are acrid and bitter. It is said that wood pigeons eat the root with great avidity, and its growth is sometimes encouraged in the vicinity of gardens to prevent their depredations in winter."

HAMPTON COURT GARDENS.

IN such a peculiar season as the present one horticulturists will not expect to see any brilliant displays in the metropolitan parks, and the majority of gardeners have had a somewhat doleful experience of conventional "bedding-out" defects in a wet summer. Zonal Pelargoniums, say the county reports, are extraordinarily vigorous in growth and foliage, but the flowers are scarce, and with few exceptions this corresponds with what we have seen. Such beds, when devoid of flowers, have a poor appearance, and those flower gardeners who have not relied exclusively upon Pelargoniums to furnish the colour considered requisite in some gardens have gained materially by their precaution. Pelargoniums are of unquestioned usefulness, and they can be employed with excellent effect in moderation; but where beds of dazzling scarlet are provided too liberally the result in hot sunny weather is at least fatiguing and often nauseating. It always seems strange that we should have in our gardens an array of the brightest colours at a time when the eye needs rest and finds the greatest relief in the fresh green turf or varied green tints of trees and shrubs. Probably this is one reason why carpet bedding has been extended so much of late years; its softer colours afford an agreeable contrast to those of the Pelargoniums, and when the designs are not too intricate or laboured such beds are welcomed for the diversity they provide. Certainly this season nothing can be urged against them on the score of excessive brightness, for the *Alternantheras*, upon which the effect of these beds is mainly dependent, have refused to assume their usual tints. *A. amœna*, *A. versicolor grandis*, and *A. amabilis* have until quite recently had an uncommonly dull appearance, the only ones which seem to have profited by the frequent rains being the golden varieties of *A. paronychioides*.

At Hampton Court we always look for excellent representations of the carpet bedding style, as the superintendent, Mr. Graham, has made it a special feature for some years, and this season visitors will not be disappointed in the designs, although the colouring is necessarily deficient. A few of the most effective beds may be briefly noted, but it is difficult to convey an accurate idea of these designs by mere verbal descriptions. As a groundwork plant *Herniaria glabra* is largely employed, and though this looks particularly well in bright weather when the *Alternantheras* are in their true character, it is a little too dark and dull in a season like the present. The *Leucophyton* also has not grown so freely as usual, and consequently some of the lines are rather thin. The dark *Iresine Wallis* takes the place of *Alternantheras* in one or two beds with evident advantage, its rich dark foliage contrasting capitally with lighter leaved plants of the *Meibomia* or *Leucophyton* character; it requires, however, to be kept closely pinched. The grey

leaved *Veronica incana* is freely employed as a groundwork plant with good results, but the *Mesembryanthemum cordifolium variegatum* looks the best, having both grown and coloured satisfactorily. *Echeveria Peacocki* is one of the Hampton Court specialities, and in its admirable condition, the ordinary *Echeveria secunda glauca* and *Sedum glaucum* with a few other succulents, appear much better than might have been expected.

The majority of the carpet beds are oblong in form, and of so large a size that only bold, well defined designs and close planting can render them satisfactory; a multiplicity of minute panels would have a very disappointing effect, as indeed they do in most cases. One good design consists of a series of S-like scrolls in the centre of *Alternanthera paronychioides* major upon a groundwork of *Mesembryanthemum cordifolium variegatum*, with seven small alternate circles of *Leucophyton* and *Alternanthera versicolor grandis*. On the outside of this are bands of *Herniaria* and *Alternanthera paronychioides*, and scrolls of *A. magnifica*, with *Mesembryanthemum*, also on a ground of *Herniaria*. The edging is of *Echeveria secunda glauca* and *Sedum glaucum*. Another carpet bed of similar form has a centre of *Echeveria Peacocki*, surrounded by bands of *Mesembryanthemum*, at each side being harps of *Alternanthera versicolor grandis* on a ground of *Leucophyton*, three "strings" being formed of *Alternanthera aurea* and two of *A. amoena*. The corners of the bed are filled with *Alternanthera aurea*, which has coloured remarkably well, panels of *A. amoena* and crescents of *A. purpurea* being employed in the same bed. This is effective, but there is a little too much artificiality in the design to please some tastes. In a third bed is a centre of *Pachyphyton roscum*, surrounded by bands of *Abutilon vexillarium variegatum*, two bold crescent-like panels being placed on each side of the centre of *Alternanthera versicolor grandis*, which has assumed a fairly rich colour. The principal groundwork is of *Herniaria*, the ends of *Mesembryanthemum*, with panels of the Golden *Alternanthera*, *Echeveria Peacocki*, a few small circles of the dark *Iresine Wallisi*, and scattered plants of *E. metallica glauca*.

But the flower garden attractions of Hampton Court do not rest exclusively upon the carpet beds, as numbers of large and small beds are occupied with "mixtures," "combinations," "harmonies," or "contrasts" to suit the fancies of all. The system of associating several different kinds of plants in one bed, not in formal quadrangular figures or hard angular designs, but freely and naturally, has extended greatly in recent years, and as carried out in the London parks it has proved reliable when other systems have failed. It presents a wide range for the exercise of ingenuity in forming fresh "combinations," and there is practically no limit to the variations that can be introduced. In the absence of these beds the garden this year would have had a much duller appearance.

One of the "mixtures" that looks well comprises *Salvia patens*, *Abutilon naevium maculatum*, and a dwarf *Tropæolum*, edged with *Iresine Wallisi*. Near this is a bed of *Petunias*, *Iresine Lindeni*, and *Acer Negundo variegata* pegged down, the whole edged with *Abutilon vexillarium variegatum*. A third includes *Pelargonium Henry Jacoby*, bordered with Golden Harry Hiever and *Viola Tory* mixed. Another of a similar character has *Pelargonium Amaranth* in the centre, with a broad mixed border of *Pelargonium Mrs. Pollock* and *Viola Tory*, edged with variegated *Alyssum*. A handsome mixed bed is formed of the variegated *Pelargonium Manglesi* and dark blue *Violas*, bordered with *Iresine Lindeni*, most effective and beautiful. Larger beds of standard *Roses* with the ground carpeted with *Heliotrope*, or of dwarf plants of *Rose Souvenir de la Malmaison* mixed with *Pelargonium St. George* also attract notice. Similar ideas are followed out in many other beds, though there are also some of the ordinary "massed" beds of *Pelargoniums*, and amongst these *Henry Jacoby* is far and away the best, being in fact almost the only Zonal *Pelargonium* which has endured the wet season satisfactorily.

The borders of herbaceous plants are gay *Phloxes*, looking especially well, and *Boconia cordata* has flourished surprisingly. Other conspicuous plants are *Helianthus multiflorus*, *Lilium auratum*, the yellow *Achillea ægyptiaca*, with *Clematis Jackmanni* on the walls. It is almost needless to say that the gardens are kept in the admirable condition which has so long marked Mr. Graham's superintendence.

COMMERCIAL FLORICULTURE AND AMERICA.

[Read before the Massachusetts Horticultural Society by Mr. W. J. Stewart of Boston.]

THE whole history of commercial floriculture in this country is progress—progress so rapid and so remarkable that it seems almost incredible. What is commercial floriculture? What is a florist? So great has been the development in all lines of business connected with the introduction, culture, and sale of floral productions that our language even has not kept pace with the business; and so we find a great combination of industries for which we have no distinctive or generally accepted names. Thirty years ago, when one spoke of a gardener or a florist everyone knew what was meant. What is a gardener now? Who are the florists?

I am sure that if I were to confine this essay to a narration merely of the progress in the culture of flowers for commercial purposes, I should not be fulfilling the duty expected by your Committee. They desire also to hear something about the great modern marts, where cut flowers are distributed, arranged, and sold, and which a few years ago did not exist. But what have those places to do with floriculture? Many of those employed in them never potted a plant, never syringed a house; many of them know as little of the details required to perfect

the flowers they sell as they do of the manufacture of the wire and tin-foil they use, or the baskets they fill, yet they occupy an important place in the florist's business of to-day. The little industry which forty years ago was only in the embryo state has during the past twenty years made such strides, and its present rate of growth is so great, that it looks as though the future will have to coin new words if it will keep up with the florist's trade.

The commercial idea, this trading in cut flowers by the dozen or hundred, I am well aware is an unwelcome subject to some well-meaning people. I recall a conversation with a gentleman whom you all know, and whose fame as a botanist is world wide, in which he made some inquiries regarding my employment, and I shall never forget the look of disgust which overspread his face as he said, "Yes, yes, peddle them out so much a barrel, just as you would Potatoes." There are doubtless many people who agree with him; they grow a flower for itself, they say, and not for its value in dollars and cents. But where do our most beautiful flowers, our most luscious fruits come from, and whom shall we thank for them? They are in many cases, no doubt, primarily the result of the labours and studies of men who have done the work for the love of it alone; but had it not been for that ever-present and all-powerful element in human nature, the desire for gain, and the energy and enterprise begotten of business methods, these prized results of love's labour would have stayed in the spot where they first saw the light, in the possession only of their originator or his immediate friends, and the millions who have enjoyed them would have never known that pleasure.

In these latter years, however, some of our most earnest students of plant life, and of methods of fertilisation and propagation, those who are striving hardest to discover or to produce new varieties, are not amateurs, nor are they enthusiasts, working solely for love of the work, but they are men who know the value in hard cash of anything meritorious. The spirit which has spanned the Continent with railways, and covered it with a maze of telegraph wires, which lines our streets with magnificent buildings and tasteful stores, and which has thrown the treasures of the whole world at our feet, is the same identical spirit as that which animates and spurs on our great hybridisers and rosarians, and which ransacks every corner of the earth, braving the dangers of the wilderness and the pestilence of the tropics in the great quest for something new or rare.

The florist of a generation ago was in most cases a rather humble and obscure individual. He was generally a man who was employed by one or several parties to keep their grounds in order, and occupying as he did a station socially about on a plane with the coachman and ostler he was expected to be as expert at milking the cow and wheeling out the ashes as he was at tying bouquets. His hothouses were of the crudest pattern; small, inconvenient, poorly heated, and set with but little regard to fitness of location or aspect. Our modern devices for heating, ventilating, and propagating were unknown to him, and he was as innocent as a child regarding the much-discussed questions of the comparative merits of hot water and steam, theories of circulation and radiation, and many other problems that interest his more fortunate brother of the present day. His stock of plants was more of a museum than anything else, and occasionally it was mainly a hospital. The hospitals in some instances are unfortunately still to be found. His bouquets, if we could see them now, would be regarded as curiosities. With a stick in the middle to keep them straight, and the flowers wound on as tightly as they could be packed together, they were indeed marvels of workmanship. About the only designs attempted besides bouquets were wreaths and a few crosses. These were fashioned on sticks or hoops.

(To be continued.)

ROSE CLARE CARNOT.

I CAN only remember one instance in which any correspondent has brought the claims of this Rose before the readers of the Journal, and yet for a late blooming variety we have no other that is so generally satisfactory. Being of a rambling habit we allowed it to have pretty much its own way as to how it will grow, only cutting back when personal comfort or the well-being of a neighbouring plant necessitates it. Its clean growth is particularly pleasing, and the truss of bloom which terminates each shoot rivals the more popular W. A. Richardson in delicacy of shape and depth of colour. Coming into bloom just as most other Roses are waning is a point in its favour which ought not to be overlooked. Though by no means suitable for exhibition, it worthily deserves a place in every Rose garden.—M. D.

AUTUMN ROSES.

IT is said the wood of plants and trees must be ripe to ensure floriferousness, and that much sun is essential for the maturation of growth. This year we have not had much but little sun, therefore the wood of Roses cannot be so ripe as is usual at this season, and consequently we ought not to expect such a good autumn bloom as usual; yet I have seen very fine stands of Roses at flower shows during the past

week, and the few trees in my garden are flowering very well. What is the condition of Roses generally? Information respecting the best autumn bloomers would be acceptable.—L. PAGE.

ROSE SPORTS.

MR. W. E. RAILLEM's article in your number for August 23rd induces me to forward a curious case of duplex variation in a Rose, Countess of Oxford, which has already been the parent of two sports new in commerce, Pride of Reigate and Pride of Waltham.

About seven or eight years ago a small shoot appeared on one of my plants differing most remarkably from the normal form. The leaves were mottled and veined with yellow, and the flower, instead of the dark red proper to the Rose, to which it belonged, was striped pink (not red as in Pride of Reigate) and white. It was irregular in shape, and the ends of the petals ragged, owing to the white portions not advancing in growth proportionally to the pink. In itself it was worthless, but out of curiosity, and to see whether it might improve, I inserted the only two buds I could get into good Briar-cutting stocks. They took, but the flowers did not improve, while the growth remained dwarf, only the leaf variations disappeared.

This went on for five or six years, and the plants would have been taken up, but that they stood in a corner which was not especially wanted. In 1886, however, I was surprised to see a very much stronger shoot, which in due time produced a Rose differing entirely both from the original and first sport. This I have propagated, and it has come true up to the present time. The flower is a brilliant pink flesh colour, brighter and better (in my possibly partial judgment) than Pride of Waltham, a vigorous grower, but different from Countess of Oxford, more bushy, and with a greater tendency on the part of the flowers to come in clusters.

It has not as yet been seen in public, but I hope to submit it to the judgment of my friends next summer. In the meantime I think that the various complications in flower and growth in this duplex sport are worthy of attention.—DUCKWING.

THE WEATHER AND GARDEN CROPS.

WE have received more communications than we anticipated in response to our invitation, and a few more remain to be published; our correspondents are thanked for the attention they have given to the subject.

BERKSHIRE.

I CANNOT give you the exact quantity of rain that has fallen in this district of late, but it has been much above the average for June and July. Garden crops, such as Peas, have run to haulm too much, and the pods would not fill. It suited Celery, Carrots, and other winter vegetables.

Bedding Pelargoniums have scarcely any flowers; Heliotropes are flowering freely, also Lobelias, Verbenas, herbaceous Phloxes; the scarlet Lychnis, Antirrhinums, and Pinks, have been very gay with us.

Pears are a fair crop on the walls; Apples are far below the average; Plums are very plentiful; Apricots, Peaches, and dessert Cherries under glass coping are an excellent crop, had to be thinned; Morello Cherries are above the average.—CHAS. HOWE, *Benham Park Gardens, Newbury.*

CHESHIRE.

I THINK your correspondent from Cheadle takes a somewhat gloomy view of the season now hastening to its close. The only downright failure here (two miles from Cheadle) is in Strawberries, other small fruits, especially Raspberries, being fully up to the average. Peas, Carrots, Lettuces, Onions, Turnips, and Celery are first-rate. Cabbages and Cauliflowers were rather late, as the severe winter destroyed all Cabbages unprotected, and the dry spring retarded the Cauliflowers. I cut my first Vegetable Marrows on August 16th, and have plenty more ready. Up to date Potatoes have been first-class. For the last three years I have pinned my faith to Sutton's Early Regent; it is a good early, better for second early, and better still as a keeper. In the matter of Roses I agree with your correspondent about Général Jacqueminot, but I should like to put in a plea for Marie Baumann, which has fully kept up its good reputation.—CONTANGE.

DERBYSHIRE.

THE weather in this part of Derbyshire during the month of May was very dry, with extremely cold cutting E. and N.E. winds. June and July were very wet and cold. We had two fine, bright and hot days on June the 18th and 26th. Taken on the whole I cannot remember so cold, wet, and sunless a July as that which has recently passed. Vegetation consequently was in a very backward state. Many Apple trees in this locality were covered with bloom, and as we escaped frost, there is on some trees an abundant crop of fruit. Plums and Pears are a moderate crop. Cherries, especially Morellos, good. Gooseberries, Currants, and Raspberries a very heavy crop, the fruit fine and clean, but short of flavour. Strawberries have been fairly good with us, fruit large and clean. On the whole, I think I may safely say that the general condition of outdoor fruit in this district will compare favourably with some more favoured localities.

Turning to vegetables, Peas have, till recently, proved unsatisfactory. the long continued wet weather causing an undue development of growth. Now, with finer and warmer weather I trust the later crops
